Organic Chemistry.

Preparation of $\Delta^{\alpha\gamma}$-Butadiene and its Homologues. BADISCHE ANILIN- & SODA FABRIK (D.R.-P. 252499).—When hydrogenated hydrocarbons of the benzene series containing at least one double bond are heated at high temperatures at the ordinary or (preferably) reduced pressures with an indifferent gas (such as nitrogen), they yield derivatives of butadiene. Isoprene is thus obtained from the lower-boiling fractions furnished by the decomposition of 1-methyl-Δ^1-*cyclo*hexene; or of 1-methyl*cyclo*hexan-2-ol, whilst *cyclo*hexene yields $\Delta^{\alpha\gamma}$ butadiene (erythrene), and 1-methyl-Δ^2-*cyclo*pentene furnishes piperylene, $CH_3 \cdot CH{:}CH \cdot CH{:}CH_2$.   F. M. G. M.

Preparation of Isoprene. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 251216).—When *as*-dimethylallene (b. p. 39—41°) is dropped on to strongly heated aluminium oxide, preferably under a pressure of about 20—30 mm., it is converted into pure isoprene; the aluminium oxide can be replaced by other catalytic agents, and the formation of higher polymerides must be avoided.   F. M. G. M.

Preparation of $\beta\gamma$-Dimethylerythrene. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 253081. Compare A., 1912, i, 741).— The preparation of $\beta\gamma$-dimethylerythrene by heating pinacone (1 part) with dilute sulphuric acid (10 parts) is described in the literature; it is now found that the most favourable proportions are 1 part of sulphuric acid (20%) to 10,000 parts of pinacone heated at 130—140°,

when a yield of over 70% of $\beta\gamma$-dimethylerythrene is obtained. The sulphuric acid can be replaced by methanedisulphonic or naphthalene-1 : 5-disulphonic acid.   F. M. G. M.

The History of Distillation and of Alcohol. HERMANN SCHELENZ (*Zeitsch. angew. Chem.*, 1912, **25**, 2526—2527).—Polemical against von Lippmann (A., 1912, i, 824 ; ii, 897).   C. H. D.

Preparation of Homologues of Pinacone. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 251330, 251331).—The homologues of pinacone can be readily prepared in satisfactory yield by the action of aluminium amalgam on the homologues of acetone.

$\gamma\delta$-*Diethylhexane*-$\gamma\delta$-*diol*, OH·CEt$_2$·CEt$_2$·OH, m. p. 27—28°, b. p. 116—119°/17 mm., is thus obtained from diethyl ketone. $\gamma\delta$-*Dimethyl-hexane*-$\gamma\delta$-*diol*, OH·CMeEt·CMeEt·OH, b. p. 78—79°/3 mm., is prepared from methyl ethyl ketone, whilst methyl propyl ketone furnishes $\delta\epsilon$-*dimethyloctane*-$\delta\epsilon$-*diol*, OH·CMePr^a·CMePr^a·OH, m. p. 95°, b. p. 116—170°/15 mm. These reactions can be carried out in either benzene or carbon tetrachloride solutions.

II. States that magnesium and mercuric chloride in the presence of cuprous chloride can replace the aluminium amalgam in these preparations.   F. M. G. M.

The Formation of Polyatomic Rings. ADOLF FRANKE and O. KIENBERGER (*Monatsh.*, 1912, **33**, 1189—1203).—In a repetition of the work of Alberti and Smieciuszewski (A., 1906, i, 619) the authors converted $\alpha\kappa$-dihydroxydecane into the chlorohydrin, but found that the product contained also about 15% of the corresponding dichloride, and that the mixture could not be satisfactorily separated ; the constitution of the chlorohydrin was proved by re-conversion into the glycol. Heating the impure chlorohydrin with sodium hydroxide and sand gave rise to a mixture of substances of high molecular weight, but no indication of the heterocyclic isomerides, $C_{10}H_{20}O$, described earlier (*loc. cit.*).

Endeavours to prepare cyclic molecules from $\alpha\kappa$-dibromodecane (Franke and Hankam, A., 1910, i, 460) by the action of ordinary zinc dust in aqueous alcohol produced *n*-decyl alcohol, whilst the action of sodium in ether gave *n*-decane, together with a *substance*, $C_{20}H_{40}$ or $C_{20}H_{42}$, silky needles, m. p. 36°.   D. F. T.

Halogen Ethers. A. KARVONEN (*Chem. Zentr.*, 1912, ii, 1266—1271; from *Acad. Sci. Fennicae.*, A, 3, 1—103. Compare A., 1909, i, 202). The boiling points and densities have been determined for a number of carefully purified halogen ethers of the series RO·CH$_2$X, RO·CH$_2$·CH$_2$X, and RO·CH$_2$·CH$_2$·CH$_2$X, where R = H, Me, Et or Pr, and X = Cl, Br or I. They have been compared with some ethylene- and trimethylene-halogen hydrins, and with some simple alkyl haloids.

In the case of metameric halogen ethers, the removal of the halogen atom from the oxygen atom frequently causes a lowering of the boiling point, but as the molecule becomes more symmetrical with regard to the groups R and (CH$_2$)$_n$X, the boiling point rises. As the distance

of the halogen atom from the oxygen atom increases, the differences between the boiling points of the chloro- and bromo- and bromo- and iodo-compounds diminish. The difference between the boiling points of the methyl and ethyl members of a homologous series is less than that between the ethyl and propyl members. The boiling points of halogen ethers with three, four, and five members in the chain are higher than those of the corresponding alkyl haloids, but with six members in the chain the ethers boil at a lower point. The hydrins boil at higher temperatures than the halogen ethers. As for the densities, the removal of the halogen atom from the oxygen atom causes an increase in density, and the halogen ethers take a mean place between the hydrins and the alkyl haloids. In general, the simultaneous separation of two negative substituents in the molecule causes an increase in density.

General methods for the preparation and purification of these compounds are discussed. The a-halogen ethers were usually prepared by the action of the hydrogen haloid on a mixture of the alcohol with trioxymethylene (compare Litterscheid, A., 1904, i, 364); the β-chloro- and bromo-ethers by the action of the phosphorus haloid on alkyloxylated alcohols, and the γ-ethers by the action of alcohols or alcoholates on alkylene haloids, the halogenating of ethers, or by the transformation of ethers into one another. The halogen ethers are all colourless, mobile liquids. The a-ethers have pungent, aldehydic odours and fume in the air, but the β- and γ-ethers are agreeable.

The following compounds are described :

A. *a-Halogen Ethers.*—Chloromethyl ether, b. p. 59·1°/766 mm., gives a *pyridine* compound, Py,CH$_2$Cl·OMe, colourless, hygroscopic tablets ; *platinichloride*, (Py,CH$_2$Cl·OMe)$_2$PtCl$_4$, reddish-yellow needles, m. p. 189°. Bromomethyl ether, b. p. 87·2°/740·6 mm. ; *pyridine* compound, Py,CH$_2$Br·OMe, very hygroscopic powder. Iodomethyl ether, b. p. 25°/13 mm. Chloromethyl ethyl ether, b. p. 83°/763·1 mm. ; *pyridine* compound, Py,CH$_2$Cl·OEt, colourless, hygroscopic tablets ; *platinichloride*, (Py,CH$_2$Cl·OEt)$_2$PtCl$_4$, reddish-yellow prisms, m. p. 182°. *Bromomethyl ethyl ether,*

$$OEt·CH_2Br,$$

from ethyl alcohol, trioxymethylene, and hydrogen bromide, b. p. 109·2°/745·7 mm. ; *pyridine* compound, Py,CH$_2$Br·OEt, white, hygroscopic. *Iodomethyl ethyl ether*, OEt·CH$_2$I, with hydrogen iodide, b. p. 31°/11 mm. ; *pyridine* compound, Py,CH$_2$I·OEt, colourless, hygroscopic. Chloromethyl propyl ether, b. p. 109°/759·7 mm. ; *pyridine* compound, Py,CH$_2$Cl·OPr, colourless, very hygroscopic; *platinichloride*, (Py,CH$_2$Cl·OPr)$_2$PtCl$_4$, m. p. 185°. *Bromomethyl propyl ether*, OPr·CH$_2$Br, from normal propyl alcohol, trioxymethylene, and hydrogen bromide, b. p. 133·9°/744·4 mm. ; *pyridine* compound,

$$Py,CH_2Br·OPr,$$
colourless, hygroscopic lamellæ. *Iodomethyl propyl ether*, OPr·CH$_2$I, with hydrogen iodide, b. p. 39°/5 mm. ; *pyridine* compound,

$$Py,CH_2I·OPr,$$
colourless.

B. *β-Halogen Ethers.*—Methyl β-chloroethyl ether,

$$OMe·CH_2·CH_2Cl,$$

by the action of phosphorus pentachloride on ethylene glycol monomethyl ether, $OMe \cdot CH_2 \cdot CH_2 \cdot OH$, and not by Fileti and Gaspari's method, b. p. 89·4°/763 3 mm. *Methyl β-bromoethyl ether*, $OMe \cdot CH_2 \cdot CH_2 Br$, from methyl β-iodoethyl ether and bromine, b. p. 110·3°/759·4 mm. Methyl β-iodoethyl ether (A., 1909, i, 202), $D_1^{20} = 1·8241$. Ethyl β-chloroethyl ether, from ethylene glycol monoethyl ether and phosphorus trichloride, b. p. 107°/751·8 mm. Ethyl β-bromoethyl ether, b. p. 40°/24 mm., from ethyl β-iodoethyl ether (*ibid*). Propyl β-chloroethyl ether, from ethylene glycol monopropyl ether and phosphorus pentachloride, b. p. 130°/756·3 mm. *Propyl β-bromoethyl ether*, $OPr \cdot CH_2 \cdot CH_2 Br$, from ethylene glycol monopropyl ether and phosphorus tribromide or hydrogen bromide, b. p. 149°/757·8 mm., 42°/11 mm. Propyl β-iodoethyl ether, $D_1^{20} = 1·5464$ (*ibid.*).

C. *γ-Halogen Ethers.*—Methyl γ chloropropyl ether, b. p. 110·4°/756·6 mm. *Methyl γ-bromopropyl ether*, $OMe \cdot [CH_2]_3 \cdot Br$, from trimethylene bromide, methyl alcohol, and zinc oxide, b. p. 132°/764·4 mm. *Methyl γ-iodopropyl ether*, $OMe \cdot [CH_2]_3 \cdot I$, from the chloroether and calcium iodide, b. p. 158—158·5°/761·8 mm. Ethyl γ-chloropropyl ether, b. p. 129°/754·7 mm. Ethyl γ-bromopropyl ether, by Noyes's method (A., 1898, i, 59), b. p. 147·8°/750 mm. *Ethyl γ-iodopropyl ether*, $OEt \cdot [CH_2]_3 \cdot I$, from the chloro-ether and calcium iodide, b. p. 172 5°/778·7 mm.

D. *Halogen Hydrins and Alkyl Haloids.*—Ethylene chlorohydrin, $OH \cdot CH_2 \cdot CH_2 Cl$, from ethylene glycol and hydrogen chloride, b. p. 129·5°/761·1 mm. Ethylene bromohydrin, $OH \cdot CH_2 \cdot CH_2 Br$, with hydrogen bromide, b. p. 45·6°/11 mm. Ethylene iodohydrin,

$$OH \cdot CH_2 \cdot CH_2 I,$$

from the chlorohydrin and sodium iodide, b. p. 61°/7 mm. Trimethylene chlorohydrin, $HO \cdot CH_2 \cdot CH_2 \cdot CH_2 Cl$, from trimethylene glycol and hydrogen chloride, b. p. 160°/734·1 mm. Trimethylene bromohydrin, $HO \cdot CH_2 \cdot CH_2 \cdot CH_2 Br$, b. p. 62°/5 mm. Trimethylene iodohydrin, $HO \cdot CH_2 \cdot CH_2 \cdot CH_2 I$, b. p. 88°/4 mm.

n-Propyl chloride, b. p. 46·6°/770·5 mm.; *n*-propyl bromide, b. p. 70·8°/769·2 mm.; *n*-propyl iodide, b. p. 101·9°/765·5 mm. *n*-Butyl chloride, b. p. 77·8°/762 7 mm.; *n*-butyl bromide, b. p. 100·2°/745·6 mm.; *n*-butyl iodide, b. p. 129·4°/746·4 mm. *n*-Amyl chloride, b. p. 105·7°/759·3 mm.; *n*-amyl bromide, b. p. 127·9°/762·4 mm.; *n*-amyl iodide, b. p. 35°/7 mm. *n*-Hexyl chloride, b. p. 132·9°/764·7 mm.; *n*-hexyl bromide, b. p. 153 4'/766·3 mm.; *n*-hexyl iodide, b. p. 51°,6 mm. J. C. W.

Preparation of Carbonic Esters. RUDOLF SCHEUBLE and A. HOCHSTETTER (D.R.-P. 252758).—*Glyceryl carbonate*, m. p. 148°, crystallises from pyridine, and is obtained in theoretical yield when anhydrous glycerol (2 parts) is heated at 140° with phenyl carbonate (7 parts) and the phenol subsequently removed in a vacuum; in this case the glycerol is fully esterified. When twice this proportion of glycerol is employed and the product extracted with a small quantity of acetone, any of the foregoing ester is left insoluble, and the acetone furnishes a complicated mixture of esters in which the glycerol is not fully esterified. These compounds can also be prepared by the action

of ethyl carbonate or carbonyl chloride on glycerol dissolved in an indifferent acid absorbing medium, and find employment in pharmacy.

F. M. G. M.

Preparation of Halogen Formyl Esters. EMANUEL MERCK (D.R.-P. 251805. Compare A., 1912, i, 877).—Chloroformyl esters can be obtained by the interaction of hydroxy-compounds with carbonyl chloride in the presence of an indifferent base or acid absorbent:

$R \cdot OH + COCl_2 = RO \cdot COCl + HCl.$

Methylhexylcarbinyl chloroformate, a colourless oil, b. p. 75°/6 mm., is obtained when a cooled benzene solution of methylhexylcarbinol (130 parts) is treated with carbonyl chloride with the subsequent slow addition of pyridine (79 parts) dissolved in 500 parts of benzene; when treated with ammonium hydroxide, it furnishes the corresponding known carbamyl ester (m. p. over 55°).

Thymyl chloroformate has b. p. 106°/10 mm., and menthyl chloroformate, b. p. 96°/5 mm.

Ethyl bromoformate, an oil with a characteristic odour, b. p. 132°/760 mm. with partial decomposition, is obtained from carbonyl bromide and ethyl alcohol in absolute ethereal solution in the presence of quinoline, whilst ethyl chloroformate is analogously prepared in the presence of methylaniline.

F. M. G. M.

Preparation of Esters of Butenol. CHEMISCHE FABRIK AUF AKTIEN VORM. E. SCHERING (D.R.-P. 252160).—When Δ^{ay}-butadienes of the general formula $CH_2 \colon CR \cdot CH \colon CH_2$ (where R is hydrogen or alkyl) are treated with a fatty acid in the presence of a condensing agent (such as sulphuric acid, zinc chloride, or potassium hydrogen sulphate), they furnish esters which are readily purified, have a characteristic odour, and on hydrolysis yield the corresponding alcohol.

Methylbutyl acetate, an oil, b. p. 100° (about), D 0·870, and saponification number 418 (about), is obtained when isoprene (100 parts), acetic acid (300 parts), and concentrated sulphuric acid (1 part) are heated together during five hours at 50°.

F. M. G. M.

The Mercury Compounds of Ethyl Nitroacetate. W. PRAGER (*Monatsh.*, 1912, **33**, 1285—1289).—The formation of ethyl mercuri-*aci*-nitroacetate anhydride, $O{<}^{NO}_{Hg}{>}C \cdot CO_2Et$, from the interaction of ammonium *aci*-nitroacetate and mercuric chloride (Scholl and Nyberg, A., 1906, i, 563), is probably preceded by the formation of a compound, $CO_2Et \cdot CH \colon NO_2 \cdot HgCl$, ethyl mercuri-*aci*-nitroacetate chloride, which, however, could not be isolated. In agreement with this idea, the yield of ethyl mercuri-*aci*-nitroacetate is increased by the addition of an equivalent quantity of sodium acetate.

The solution of ethyl mercuri-*aci*-nitroacetate in sodium hydroxide solution contains *ethyl sodium mercuri-aci-nitroacetate hydroxide*,

$CO_2Et \cdot C(\colon NO_2Na) \cdot Hg \cdot OH,$
which can be obtained as a greenish-yellow substance by evaporation with exclusion of atmospheric carbon dioxide. Ethyl mercuri-*aci*-

nitroacetate anhydride dissolves also in potassium cyanide solution, forming presumably the analogous *cyanide* compound,

$$CO_2Et \cdot C(:NO_2K) \cdot Hg \cdot CN.$$
Attempts to obtain substances of analogous structure to the above from nitroacetamide, dinitromethane, and ω-nitrotoluene produced only substances of the type $CHR:NO_2 \cdot HgCl$; nitroacetamide gave a *substance*, $Hg(NH \cdot CO \cdot CH:NO_2 \cdot HgCl)_2$; the potassium derivative of dinitromethane with mercuric chloride gave yellow needles of an explosive *substance*, $NO_2 \cdot CH:NO_2 \cdot HgCl$, together with an amorphous, yellow *substance* also containing chlorine.   D. F. T.

Action of Aluminium Chloride on Acetic Anhydride. JACOB BOESEKEN and MEYER OLUWEN (*Rec. trav. chim.*, 1912, 31, 367—369).—When acetic anhydride is added to warmed aluminium chloride, acetyl chloride distils off, leaving a heavy, white precipitate of aluminium monochlorodiacetate, which forms an *additive* compound with ether, $OEt_2, 2AlCl(OAc)_2$, in large, limpid crystals.   J. C. W.

Soaps. ALBERT REYCHLER (*Bull. Soc. chim. Belg.*, 1912, 26, 485—495. Compare Krafft and Stern, A., 1894, i, 439, 440; Krafft and Wiglow, A., 1896, i, 80; Krafft and Strutz, A., 1896, ii, 467; Krafft, A., 1899, ii, 471, 472, 473).—When sodium palmitate is crystallised from its aqueous solution, an acid soap separates, and the mother liquor becomes alkaline. Recalculation of the data given by Krafft shows that as the sodium palmitate solution decreases in concentration, so also does the concentration of sodium hydroxide in the mother liquor, the latter value, however, finally becoming constant. This is confirmed by experiments performed by the author, who, however, contrary to Krafft, finds that fatty acids are also retained in the mother liquors.

Krafft has shown that palmitic acid may be almost completely extracted from solutions of sodium palmitate by treatment with successive quantities of toluene. The author has performed a number of experiments on the quantitative extraction of the acid by a single treatment of aqueous solutions of sodium palmitate and oleate with measured amounts of toluene, and finds that the extractability depends both on the m. p. of the acid and on its solubility in toluene. The percentage of acid extracted is inversely proportional to the concentration of sodium hydroxide in the soap solution.

The bearing of the above results on the divergent action of soap is discussed, and the conclusion drawn that this action lies rather in the power of the soap solution to emulsify the grease than in the saponification of the latter by alkali. A partly rancid fat should thus be readily emulsified by a solution of soap of suitable concentration, whilst, on the other hand, a neutral fat would first acquire the necessary acidity by extraction of a portion of the acid from the soap solution.   H. W.

Dissociation Constants of Aliphatic Hydroxy- and Alkyloxy-acids. MATTI H. PALOMAA (*Chem. Zentr.*, 1912, ii, 595—597; from *Ann. Acad. Sci. Fennicae*, 1911, *A*, 3, 1—34).—The dissociation constants of a number of aliphatic hydroxy- and alkyloxy-acids have been

determined with a view to ascertaining how this constant is affected by the positions of the oxygen atoms in the ·OH or ·OR group with respect to the carboxyl group. In general, the dissociation constant diminishes with increasing distance between the two groups, until in the δ-compounds it is nearly as low as in the normal fatty acids. Attempts to calculate the effect of distance on the specific influence of the ethereal oxygen atom by means of the equations $(y/y + 2·66)^{-\lambda} = K_0^g/K_0^g$ and $(y/y + 2 \times 2·66)^{-x} = K_5^g/K_5^g$ showed that $x = 2\cdot6$ in methoxy-compounds and 2·9 in ethoxy-compounds, the values of y being 1·45 and 1·78 respectively for the same compounds.

The following substances are described: n-*Butoxyacetic acid*, D_4^{15} 1·0256, D_4^{20} 1·0213, b. p. 113—116°/9—10 mm., K 0·0219, is a colourless liquid with a not unpleasant odour. iso*Butoxyacetic acid*, D_4^{15} 1·0117, D_4^{20} 1·0074, b. p. 114°/9 mm., K 0·0214, is a colourless liquid. α-*Ethoxypropionic acid*, b. p. 97°/11 mm., K 0·0246. β-*Methoxypropionic acid*, D_4^{15} 1·1064, D_4^{20} 1·1020, b. p. 107°/10 mm., K 0·00346. β-*Ethoxypropionic acid*, D_4^{15} 1·0508, D_4^{20} 1·0641, b. p. 119—120°/19 mm., K 0·00319. δ-*Methoxyvaleric acid*, D_4^{15} 1·0387, D_4^{20} 1·0344, b. p. 133—134°/13·5 mm., K 0·00191.   T. A H.

Action of Magnesium Methyl Iodide and Bromide on Di-α-bromoisopropyl Ketone and on α Bromoisopropyl tert.-Butyl Ketone (Pentamethylbromoacetone): Synthesis of β-Hydroxy-pentamethyl-n-valeric Acid and Pentamethylvalerolactone. (Mlle.) A. UMNOVA (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1395—1406). —Instead of the expected methylditert.-butylcarbinol, the products of the interaction of di-α-bromoisopropyl ketone, magnesium methyl iodide, and water are: (1) *isopropyl tert.-butyl ketone* (compare Nef, A., 1900, i, 349), formed from the intermediate compound,

$$CMe_3·CO·CMe_2·MgBr,$$
and (2) methyl*iso*propyl*tert.*-butylcarbinol (?), b. p. 65—75°/12 mm.

The action of magnesium methyl bromide on di-α-bromoisopropyl ketone yields the compound $CMe_3·CMe(OMgBr)·CMe_2·MgBr$, the latter being converted by carbon dioxide into *β-hydroxy-aaβγγ-penta-methylvaleric acid*, $CMe_3·CMe(OH)·CMe_2·CO_2H$, m. p. 128—129°, which has the normal molecular weight in boiling ether; the *silver* and *calcium* salts were analysed. Attempted oxidation of the sodium salt of the acid with potassium permanganate and subsequent distillation of the solution with sulphuric acid yields *aaββγ-pentamethyl-valerolactone*, $CMe_2 {<}^{CMe_2·O}_{CMe_2·CO}$, m. p. 59—60°, b. p. 215—220°, which has the normal molecular weight in freezing benzene; the formation of the lactone is shown to be due to the following isomeric change effected by the sulphuric acid: $CMe_3·CMe(OH)·CMe_2·CO_2H \longrightarrow OH·CMe_2·CMe_2·CMe_2·CO_2H$. β-Hydroxy-*aaββγ*-pentamethylvaleric acid may also be obtained by the action of carbon dioxide and water on the product of the interaction of magnesium methyl iodide and α-bromoisopropyl *tert.*-butyl ketone.   T. H. P.

Optically Active Dichlorosuccinic Acids. BROR HOLMBERG (*Svensk. Kem. Tid.*, 1912; Reprint, 6 pp.).—The dichlorosuccinic

anhydride obtained by the action of chlorine on a solution of maleic anhydride in carbon tetrachloride (compare Holmberg, A., 1911, i, 767 ; McKenzie, T., 1912, 101, 1196) is a mixture of a less soluble racemic dichlorosuccinic anhydride with a more soluble *meso* anhydride in the approximate proportions 5 : 1. This behaviour is in marked contrast with the oxidation of maleic acid by potassium permanganate, when the sole product is *meso*-tartaric acid. The anhydrides on treatment with cold water gave the respective acids: r-*dichlorosuccinic acid*, tablets, m. p. 173—174° (decomp.) ; meso-*dichlorosuccinic acid*, prisms, m. p. 215° (decomp.).

By fractional recrystallisation of the salt of the racemic acid with *d*-α-phenylethylamine from warm water, there was obtained d-*phenylethylamine* d-*dichlorosuccinate*, m. p. 142—142·5°, from which the pure d-*dichlorosuccinic acid*, prisms, m. p. 164—165° (decomp.), $[a]_D^{23}$ +80·41° (in ethyl acetate), could be separated by acidifying with sulphuric acid and extracting with ether. The mother liquor from the first crystallisation of the racemic salt contained a lævorotatory acid, which, when combined with *l*-phenylethylamine and crystallised from warm water, gave a salt of the same m. p. as that containing the *d*-acid and *d*-base ; the acid isolated from this salt was pure l-*dichlorosuccinic acid*, m. p. 164—165°, $[a]_D$ (in ethyl acetate) −80·38°.

The racemic acid, m. p. 173—174°, could be re-obtained by mixing equal amounts of these aenantiomorphs.   D. F. T.

New Method of Preparation of Muconic Acid. ROBERT BEHREND and GERHARD TEN DOORNKAAT KOOLMAN (*Annalen*, 1912, 394, 228—247).—Malonic acid (2 mols.) and the sodium hydrogen sulphite compound of glyoxal are boiled with water for about an hour. The solution is evaporated to a syrup, which is boiled with glacial acetic acid for about six hours, and is then treated with 36% hydrochloric acid. The sodium chloride is removed, and the filtrate is evaporated with water to a syrup. which deposits crystals after one to two days. These are treated with 95% alcohol, collected, and crystallised from hot 80% alcohol. The product is the *lactone* of *sodium hydrogen β-hydroxy-γ-sulphoadipate*,

$$\begin{matrix} CO_2H \cdot CH_2 \cdot CH\!\!-\!\!-\!\!O \\ SO_3Na \cdot CH \cdot CH_2 \end{matrix}\!\!>\!\!CO, 3\tfrac{1}{2}H_2O,$$

prismatic crystals, m. p. 270—272° (decomp.), occasionally melting at 80—85° in its water of crystallisation, re-solidifying, and melting again at 270—272°. The *lactone* of the corresponding potassium hydrogen salt, m. p 262—264° (decomp.), is obtained in a similar manner. The *lactone* of the *sodium ethyl* salt, obtained from that of the sodium hydrogen salt, boiling 95% alcohol, and 1 drop of concentrated hydrochloric acid, forms long, felted needles containing H_2O, and has m. p. 145—147° (decomp.).

By heating on the water-bath for four hours with an alkali hydroxide and a little water, the lactone of sodium hydrogen hydroxysulphoadipate is decomposed, yielding, after solution in water and acidification, about 30% of muconic acid and 60% of succinic acid.

Muconic acid has m. p. 301—305° (decomp.), and is soluble in about 5000 parts of cold water and in about 100 parts of cold absolute alcohol.

A by-product in the preparation of the lactone is a *substance*, which is isolated as the amorphous *barium* salt, $C_{10}H_{11}O_{12}SBa_2$, from which muconic acid in a yield of 38%, but not succinic acid, can be obtained by heating with an alkali hydroxide and a little water on the water-bath.

For the preparation of muconic acid there is no need to isolate the lactone. Malonic acid and the sodium hydrogen sulphite compound of glyoxal are boiled with water for an hour, the solution is evaporated to a syrup, which is heated at 140—160° until gas almost ceases to be evolved, and is then treated with an alkali hydroxide and a little water on the water-bath, as above. C. S.

Elucidation of the Constitution of Cholic Acid by Bromination. BAREND C. P. JANSEN (*Zeitsch. physiol. Chem.*, 1912, 82, 326—341).—On bromination of cholic acid, a brown, amorphous mass is obtained, which is decomposed by sodium hydroxide, losing part of the bromine. The bromine is not completely removed on reduction either with zinc dust and alcoholic hydrogen chloride or with aluminium amalgam. Bromination in acetic acid solution is accelerated by sunlight; it is a process of substitution. The product, bromo-dehydrocholic acid, crystallises from acetic acid or from acetone in needles, decomp. 180°; when crystallised from alcohol, it forms octahedra, decomp. ±140°.

Ethyl bromodehydrocholate is obtained either by brominating ethyl dehydrocholate or by esterification of bromodehydrocholic acid. The bromine is removed quantitatively by means of sodium hydroxide from either bromodehydrocholic acid or its ester. The bromo-acid is immediately oxidised by boiling Fehling's solution or ammoniacal silver solution. Zinc dust or magnesium reduce it to dehydrocholic acid. E. F. A.

Preparation of the *p*-Bromophenylhydrazine Compound of Glycuronic Acid. ADOLF JOLLES (*Ber.*, 1912, 45, 3280—3281).—In presence of traces of impurity the crystallisation of the *p*-bromophenylhydrazine compound of glycuronic acid is prevented (Neuberg, A., 1899, i, 933). After recrystallisation of the hydrazine, the lustrous, golden-yellow needles described by Neuberg are obtained without difficulty. E. F. A.

The Action of *p*-Bromophenylhydrazine on Glycuronolactone. GUIDO GOLDSCHMIEDT and ERNST ZERNER (*Monatsh*, 1912, 33, 1217—1231).—Attempts to prepare Neuberg's compound of *p*-bromophenylhydrazine with glycuronic acid (A., 1899, i, 933), which has also been prepared and analysed by Jolles (A., 1911, i, 709), have entirely failed either when Neuberg's original directions or modifications are followed. The products actually obtained were salts of *glycuronic acid* p-*bromophenylosazone*, $CO_2H \cdot CH(OH) \cdot CH(OH) \cdot CH(OH) \cdot C(N_2H \cdot C_6H_4Br) \cdot CH:N_2H \cdot C_6H_4Br$; *sodium* salt, hygroscopic, yellow needles, m. p. 185—190°, $[a]_D$ (in alcohol and pyridine mixture) − 259° ; *barium* salt, hygroscopic, yellow

needles, m. p. 215—217° (decomp.) ; the *calcium, potassium, zinc,* and *lead* salts were also prepared.

It is suggested that the formation of the barium salt, which occurs easily and in good yield, constitutes a much more satisfactory test for glycuronic acid than does the evidently uncertain reaction of Neuberg.

<div align="right">D. F. T.</div>

The Mechanism of Oxidation Processes. OSCAR LOEW (*Ber.*, 1912, **45**, 3319).—When cuprous oxide is added to an alkaline solution of formaldehyde a vigorous evolution of hydrogen takes place, formic acid being formed. This experiment supports Wieland's idea (A., 1912, i, 944) that the oxidation of an aldehyde to an acid is a process of dehydrogenation.

<div align="right">T. S. P.</div>

aa-Bromomethylpropaldehyde. II. The Friedel - Crafts Reaction. ADOLF FRANKE and ARTUR KLEIN (*Monatsh.*, 1912, **33**, 1233—1241).—Polymeric aa-bromomethylpropaldehyde (monoclinic crystals, $a : b : c = 2\cdot6 : 1 : 4\cdot9$; $\beta = 90°7'$) only enters into synthetic reactions when the conditions are such as to cause depolymerisation (Franke, A., 1900, i, 206, 427). When treated with benzene, carbon disulphide, and aluminium chloride, hydrogen bromide is vigorously evolved and phenyl *iso*propyl ketone formed ; the oxime, tablets, m. p. 75°, with acetic anhydride yielded an *acetate,* b. p 147—149°/ 10 mm. Reduction of the ketone in aqueous alcohol by sodium amalgam gave phenyl*iso*propylcarbinol; *acetate,* b. p. 106—108°/ 9·5 mm. ; the b. p. (222—224°) of the free carbinol was considerably lower than that given earlier (Claus and Sauer, A., 1892, i, 985). Finely divided silver or copper acts on the polymeric bromomethyl-propaldehyde at 150° with the formation of *iso*butaldehyde, together with products of higher b. p.

<div align="right">D. F. T.</div>

Catalytic Reactions at High Temperatures and Pressures. XXV. VLADIMIR N. IPATIEV (*Ber.*, 1912, **45**, 3218—3226).—In addition to reduction with hydrogen under pressure in the presence of reduced nickel as catalyst, the author investigates the action of reduced palladium as catalyst. In some cases the apparatus in which the reduction was being carried out was shaken at intervals only, whilst in other cases the contents were stirred continuously by means of a stirrer actuated by a solenoid.

Reduction of β-methyl-β-ethylacraldehyde takes place at 130° in the presence of reduced nickel, but the yield of alcohol is very small, a considerable quantity of condensation products being formed. With palladium as catalyst and a hydrogen pressure of 110 atmos., reduction takes place at 110° with the formation of γ-methyl-*n*-amyl alcohol, b. p. 145—146°/758 mm., D^{18} 0·8227. The reduction takes place slowly unless continuous stirring is resorted to. Attempts to reduce the above acraldehyde in the author's apparatus, using Skita's method (A., 1909, i, 479), were unsuccessful, either at the ordinary tempera-tures or at 100°.

With palladium as catalyst, mesityl oxide is slowly reduced at 100° to methyl *iso*butyl ketone, whereas with nickel as catalyst a

mixture of methyl *iso*butyl ketone and methyl*iso*butylcarbinol is obtained at 145°.

The reduction of citral in the presence of palladium at 110°, or of a mixture of reduced nickel and nickel oxide at 140°, takes place slowly when the apparatus is continuously shaken. A mixture of products is obtained, from which $\beta\zeta$-dimethyloctane and $\gamma\eta$-dimethyloctanol were separated. When the reduction is carried out with continuous stirring, it proceeds rapidly to completion, the only product being decanol, b. p. 107—108°/12 mm., D^{18} 0.8296.

Under the same conditions as with citral, geraniol gives a mixture of decanol with small quantities of decane and condensation products when continuous shaking is resorted to, whereas with continuous stirring decanol and small quantities of decane are obtained.

At 109°, under a hydrogen pressure of 116 atmos., and in the presence of palladium as catalyst, acetylacetone is reduced to amylene $\beta\delta$-glycol, b. p. 197—198°, D^{18} 0.9602. With reduced nickel as catalyst, the reduction proceeds very slowly, the final product being a mixture of the original acetonylacetone with methyl n-propyl ketone.

By means of the apparatus with continuous stirring, the carbohydrates can readily be reduced; 20—30% aqueous-alcoholic solutions are used, the temperature being 110° with palladium as catalyst, and 130—135° with a mixture of reduced nickel and nickel oxide as catalyst; the hydrogen pressure is 100 atmos. With both catalysts, lævulose gives d-mannitol ($[\alpha]_D$ +0.71°), but the reduction is incomplete; dextrose is reduced to d-sorbitol ($[\alpha]_D$ +0.25°). Lactose is reduced to dulcitol. T. S. P.

The System Acetonephenylhydrazone-Water. JAN J. BLANKSMA (*Chem. Weekblad*, 1912, 9, 924—927. Compare Reisenegger, A., 1883, 798; Schmidt, A., 1889, 1159; Arnold, A., 1897, i, 409).— The physical data for acetonephenylhydrazone given by the investigators named are incorrect. On heating acetone with a solution of phenylhydrazine in water or dilute acetic acid, an oil is formed. When it is washed with water, dried with potassium carbonate, and distilled under reduced pressure, the product is a pale yellow liquid, b. p. 140°/16 mm., 153°/31 mm., 160°/44 mm., 163°/50 mm. Repeated solidification by cooling with a freezing mixture yielded colourless crystals, m. p. 26.6°, which on exposure to air became yellow and then brown. It forms a colourless hydrate, turned brown, and ultimately resinified by the action of air.

The author gives the fusion curves of acetonephenylhydrazone, its hydrate, and water. The solubility of the hydrate per 100 c.c. of water is 0.09 gram (0°), 0.187 gram (15°), and 0.412 gram (32.8°). A. J. W.

Syntheses by means of Mixed Organo-zinc Derivatives, α-Polychloroketones. Constitution of the Ordinary Trichloroacetone. EDMOND E. BLAISE (*Compt. rend.*, 1912, 155, 1252—1253. Compare A., 1912, i, 606).—Dichloroacetyl chloride readily condenses with α-hydroxy*iso*butyric acid to form *dichloroacetoxyisobutyric acid*, $CHCl_2 \cdot CO_2 \cdot CMe_2 \cdot CO_2H$, m. p. 95°. The corresponding *acid chloride*,

b. p. 103°/12 mm., yields an *anilide*, m. p. 99—100°, and condenses with zinc ethyl iodide, giving the *cycloacetal*, $C_5H_{12}O_3Cl_2$, m. p. 51°, b. p. 124·5—125°/16 mm., which on hydrolysis with a mixture of acetic and hydrochloric acids yields *dichloromethyl ethyl ketone*,

$$CHCl_2 \cdot COEt,$$
b. p. 138·5—139°. This ketone with hydroxylamine gives ethyl glyoxaldioxime, m. p. 128°. Attempts to convert the ketone into the corresponding keto-aldehyde were not successful.

Trichloroacetoxyisobutyryl chloride, b. p. 113°/18 mm, can be similarly prepared, and gives an *anilide*, m. p. 100°. The *acid* has m. p. 117°, and with zinc methyl iodide gives the *cycloacetal*,

$$C_7H_9O_3Cl_3,$$

m. p. 98—99°, which on hydrolysis yields *as-*trichloroacetone, $CCl_3 \cdot COMe$, b. p. 134°. Its *semicarbazone* crystallises in needles, m. p. 140°. Ordinary trichloroacetone, b. p. 172°, obtained by the chlorination of acetone, must therefore be the unsymmetrical compound (compare Schotterbeck, A., 1909, i, 553).   W. G.

## Action of Halogen Compounds of Phosphorus on Ketones : Bromo-ketones, and Keto-alcohols. ALEXEI E. FAVORSKI (*J. Russ. Phys. Chem. Soc.*, 1912, 44, 1339—1395).

—According to Henry (*Ber.*, 1875, 8, 400) the action of phosphorus pentachloride on diisopropyl ketone results in replacement of the carbonylic oxygen by two atoms of chlorine, the compound thus formed giving $\beta\delta$-dimethyl-$\Delta^{\beta\gamma}$-penta-diene when treated with alcoholic potassium hydroxide. The author finds, however, that the principal product of this action is not a dichloro-compound, but *isopropyl* α-chloro*isopropyl* ketone,

$$CMe_2Cl \cdot CO \cdot CHMe_2.$$
Further, in the case of *isopropyl tert.*-butyl ketone, the reaction proceeds similarly, α-chloro*isopropyl tert.*-butyl ketone being mainly obtained. With phosphorus pentabromide, the reaction takes place in the above direction with all ketones, and of a number of these compounds examined, only pinacolin underwent to some extent replacement of its carbonylic oxygen by two bromine atoms.

The ability of the carbonyl group of a ketone to react with phosphorus pentahaloid depends on the structure of the ketone and on its greater or less capacity to undergo enolisation. Ketones of normal structure (mono- and di-substituted acetones) readily react in the cold with phosphorus pentachloride by means of their carbonyl group, the oxygen of which is replaced by chlorine. On the other hand, such ketones as diisopropyl ketone, and, more especially *isopropyl tert.*-butyl ketone, react with phosphorus pentachloride only in the hot, when they undergo enolisation, the action of the chlorine liberated by dissociation of the pentachloride resulting in the formation of a mono-chloroketone :

(1) $CMe_2:O + PCl_5 = CMe_2Cl \cdot OPCl_4 = POCl_3 + CH_3 \cdot CCl_2 \cdot CH_3$;

(2) $CHMe_2 \cdot CO \cdot CHMe_2 \longrightarrow CMe_2:C(OH) \cdot CHMe_2 + Cl_2 =$
$$CMe_2Cl \cdot CO \cdot CHMe_2 + HCl.$$
Phosphorus pentabromide dissociates more readily, both on heating and in solution, than the pentachloride, and exerts, therefore, increased enolising action on the ketones, which yield mainly bromoketones :

$CMe_2{:}O \longrightarrow CH_3{\cdot}C(OH){:}CH_2 + Br_2 = CH_3{\cdot}CO{\cdot}CH_2Br + HBr$. Experiment shows, indeed, that the action of bromine on ketones yields the same products as that of phosphorus pentabromide, the latter, however, acting more vigorously owing to the enolising action of the bromine formed on dissociation of the pentabromide being more energetic than the action of free bromine; for instance, *iso*propyl α-bromo*iso*propyl ketone is not acted on by bromine, but is converted into the dibromo-derivative when heated with phosphorus pentabromide on a water-bath.

The first bromine atom enters the ketone molecule in the α-position with respect to the carbonyl group and mostly replaces a hydrogen atom of the less highly hydrogenated hydrocarbon group. The second bromine atom proceeds mostly to the same carbon atom as the first, so that unsymmetrical αα-dibromoketones are obtained in preponderating amount. If, however, the first bromine atom replaces the only hydrogen atom combined with the first of the α-carbon atoms, the second bromine atom becomes united with the other carbon atom adjacent to the carbonyl group, symmetrical dibromoketones being obtained. Tribromoketones may also be formed by the replacement of all three hydrogen atoms united to the carbon atoms in the α-positions.

[With I. IDELSON and (Mlle.) A. UMNOVA.]—iso*Propyl* α-*chloro*iso*propyl ketone*, $CMe_2Cl{\cdot}CO{\cdot}CHMe_2$, is a colourless liquid, b. p. 142°/760 mm., 92°/150 mm., D_0^0 0·9800, D_0^{20} 0·9592, giving no compound with semicarbazide. By alcoholic potassium hydroxide it is converted into iso*butyryldimethylcarbinol*, $OH{\cdot}CMe_2{\cdot}CO{\cdot}CHMe_2$, which is a colourless liquid with an odour like that of camphor, b. p. 164·5—165°/761 mm., D_0^0 0·9408, D_0^{20} 0·9239, and forms a *semicarbazone*, $C_8H_{17}O_2N_3$, m. p. 196°, in either aqueous or alcoholic solution (compare Kling, A., 1905, i, 503). Reduction of the keto-alcohol yields : (1) βγ-dihydroxy-βδ-dimethylpentane, $OH{\cdot}CMe_2{\cdot}CHPr^\beta{\cdot}OH$, m. p. 59°, and (2) di*iso*-propylcarbinol. Conversion of di*iso*propylcarbinol into the corresponding γ-iodo-βδ-dimethylpentane, $CHMe_2{\cdot}CHI{\cdot}CHMe_2$, and treatment of the latter with alcoholic potassium hydroxide yields βδ-*dimethyl*-Δ*β-amylene*, $CMe_2{:}CHPr^\beta$, b. p. 82—84°, oxidation of which gives *iso*butyryldimethylcarbinol (see above) (compare Blaise and Herman, A., 1910, i, 534).

[With E. FRICMAN.]—iso*Propyl* tert.-*butylcarbinol*,

$$OH{\cdot}CHPr^\beta{\cdot}CHMe_3,$$

obtained by the action of magnesium *tert.*-butyl chloride on *iso*but-aldehyde, is a liquid, b. p. 150—151°/760 mm., D_0^0 0·8479, D_0^{10} 0·8298, m. p. − 13°, with a camphor-like odour. On oxidation it yields *iso*-*propyl* tert.-*butyl ketone*, $COPr^\beta{\cdot}CHMe_3$, which is a mobile liquid, b. p. 134—135°/760 mm., D_0^0 0·8240, D_0^0 0·8065, with an intense camphor-like odour; neither the hydrazone nor the semicarbazone could be obtained. Treatment of the ketone with phosphorus pentachloride in a sealed tube at 140° gives : (1) α-*chloroiso*propyl tert.-*butyl ketone*, $CMe_2Cl{\cdot}CO{\cdot}CMe_3$, b. p. 79—110°/18 mm., which yields Butlerov's oxoctenol, $\begin{smallmatrix}CMe_2\\O\end{smallmatrix}{>}C(OH){\cdot}CMe_3$ (A., 1882, 936), on treatment with

potassium hydroxide solution; (2) $\gamma\gamma$-*dichloro-$\beta\beta\delta$-trimethylpentane*, CMe$_3$·CCl$_2$·CHMe$_2$, b. p. 122—125°/19 mm.

[With B. ISATSCHENKO.]—The action of phosphorus pentabromide on acetone yields bromoacetone, and that of the pentabromide or bromine (1 mol.) on methyl ethyl ketone gives *methyl α-bromoethyl ketone*, which is a liquid, b. p. 35—38°/12 mm., D$_{20}^{20}$ 1·4380. With 2 mols. of bromine, methyl ethyl ketone yields (1) *bromomethyl α-bromoethyl ketone*, CH$_2$Br·CO·CHMeBr, b. p. 194—195°, 80—83°/ 10 mm., D$_{20}^{20}$ 1·9729; (2) a tribromo-derivative of the ketone.

[With A. VANSCHEJDT.]—The action of phosphorus pentabromide on methyl *iso*propyl ketone yields: (1) *Methyl α-bromoisopropyl ketone*, CH$_3$·CO·CMe$_2$Br, b. p. 49°/22 mm., 139°/760 mm., D$_4^{20}$ 1·3377, which is converted into acetyldimethylcarbinol (compare Diels and Johlin, A., 1911, i, 254) when heated in a sealed tube with potassium formate at 130° (compare Kling, A., 1905, i, 503); the *acetyl* derivative of the carbinol, C$_7$H$_{12}$O$_3$, b. p. 65°/15 mm., 170—171°/ 760 mm., forms the *oxime*, C$_7$H$_{13}$O$_3$N, m. p. 102—103°. (2) *Bromomethyl α-bromoisopropyl ketone*, CH$_2$Br·CO·CMe$_2$Br, which is best obtained by the action of bromine on the preceding compound, and is a colourless liquid, b. p. 99°/18 mm., m. p. 10°, D$_{20}^{20}$ 1·830, yielding no crystalline products with hydroxylamine, phenylhydrazine, or semicarbazide. With alcoholic potassium hydroxide (compare Favorski, A., 1895, i, 496; Semenov, *J. Russ. Phys. Chem. Soc.*, 1911, 48, 693) it yields $\beta\beta$-dimethylacrylic acid (compare Weinig, A., 1895, i, 17). (3) *Dibromomethyl α-bromoisopropyl ketone*, CHBr$_2$·CO·CMe$_2$Br, which forms colourless, silky needles, m. p. 52°, b. p. 110—115°/6 mm., D$_{21}^{22}$ 2·051, D$_{21}^{22}$ 2·268. By aqueous potassium hydroxide, this ketone is converted into $\beta\beta$-dimethylglyceric acid, OH·CMe$_2$·CH(OH)·CO$_2$H, the *iso*butyl ester of which, C$_9$H$_{18}$O$_4$, is a viscous liquid, b. p. 230° (decomp.), 121°/11 mm., D$_{21}^{21}$ 1·0774, D$_4^{21}$ 1·0752. When distilled in presence of sulphuric acid, $\beta\beta$-dimethylglyceric acid yields α-hydroxy-*iso*butaldehyde. These three bromo-ketones are also obtainable from methyl *iso*propyl ketone by the action of bromine, which gives, in addition, a *tetrabromo*-derivative, C$_5$H$_6$OBr$_4$, b. p. 157°/27 mm., D$_{21}^{21}$ 2·446.

[With T. VELITSCHKOVSKI.]—The action of phosphorus pentabromide on pinacolin yields: (1) *Bromomethyl tert.-butyl ketone*, CH$_2$Br·CO·CMe$_3$, which is a liquid with a pungent odour, b. p. 70—73°/9 mm., D$_0^{20}$ 1·3274, D$_0^0$ 1·3508, and reduces Fehling's solution in the cold. When heated with water and freshly-precipitated barium carbonate, it yields *hydroxymethyl tert.-butyl ketone*, OH·CH$_2$·CO·CMe$_3$, which is a liquid, b. p. 158—160°, 52·5°/12 mm., m. p. +9·5°, D$_{20}^{20}$ 0·95295, D$_0^0$ 0·95164, D$_0^{13\cdot5}$ 0·9576, and yields an *oxime*, C$_6$H$_{13}$O$_2$N, m. p. 89—90°, and a *phenylosazone*, C$_{18}$H$_{22}$N$_4$, m. p. 119—120°. Oxidation of this keto-alcohol yields first the corresponding keto-aldehyde and then α-hydroxy-$\beta\beta$-dimethylbutyric acid, CO$_2$H·CH(OH)·CMe$_3$. (2) Dibromomethyl *tert.*-butyl ketone, CHBr$_2$·CO·CMe$_3$ (compare Kondakov, A., 1899, i, 859; Wittorv, A., 1900, i, 421). (3) *$\beta\beta$-Dibromo-$\gamma\gamma$-dimethylbutane*, CH$_3$·CBr$_2$·CMe$_3$, m. p. 191—191·5°.
[With D. Sciborski.]—The action of phosphorus pentabromide on ethyl *isopropyl* ketone yields: (1) *Ethyl α-bromoisopropyl ketone,* $CBrMe_2 \cdot COEt$, b. p. 50—53°/13 mm., D_1^{20} 1·2847, D_1^{0} 1·3098, which gives *ethyl α-hydroxyisopropyl ketone,* $OH \cdot CMe_2 \cdot COEt$, b. p. 95—97°/100 mm., D_4^{0} 0·9548, D_4^{20} 0 9446, D_0^{20} 0·9405, when heated with water and freshly-precipitated barium carbonate, and (2) *α-bromoethyl α-bromoisopropyl ketone,* $CHMeBr \cdot CO \cdot CMe_2Br$, b. p. 80—81°/13 mm.

[With P. Aschmarin.]—*Ethyl*tert.-*butylcarbinol,* $OH \cdot CHEt \cdot CMe_3$, obtained by the interaction of magnesium *tert.*-butyl chloride and propaldehyde, is a liquid, b. p. 132—135°, 42—44°/15 mm., D_4^{0} 0·84078, D_4^{20} 0·82462. It forms an *acetyl* derivative, $C_9H_{18}O_2$, b. p. 157—159°/770 mm., and on oxidation yields *ethyl* tert.-*butyl ketone,* $CMe_3 \cdot COEt$, b. p. 125—126°/769 mm., D_4^{0} 0·8303, D_4^{20} 0·8125, which gives a *semicarbazone,* $C_8H_{17}ON_3$, m. p. 144°. The action of phosphorus pentabromide on this ketone yields: (1) *α-Bromoethyl* tert.-*butyl ketone,* $CHMeBr \cdot CO \cdot CMe_3$, b. p. 67·5—68·5°/11 mm., D_4^{0} 1·2687, D_4^{20} 1·2456, and (2) *αα-dibromoethyl* tert.-*butyl ketone,* $CMeBr_2 \cdot CO \cdot CMe_3$, m. p. 77·5—79°/10 mm., D_4^{0} 1·5955, D_4^{20} 1·5674. *Trimethylacetylmethylcarbinol,* $OH \cdot CHMe \cdot CO \cdot CMe_3$, obtained by way of its *acetyl* derivative, $OAc \cdot CHMe \cdot CO \cdot CMe_3$, b. p. 189—191°, from α-bromoethyl *tert.*-butyl ketone, is a liquid, b. p. 100—101·5°/100 mm., D_4^{0} 0·9483, D_4^{20} 0·9301, with a faint camphor-like odour and yields a *semicarbazone* in two modifications, m. p. 98—100° and 135° respectively.

[With (Mlle.) A. Umnova.]—The action of bromine on di*iso*propyl ketone yields *isopropyl α-bromoisopropyl ketone,* $CMe_2Br \cdot CO \cdot CHMe_2$, b. p. 166—168°, 50—51°/10 mm., D_0^{0} 1·2763, D_0^{20} 1·2636, which is converted by phosphorus pentabromide into *di-α-bromoisopropyl ketone,* $CO(CMe_2Br)_2$, a yellow liquid with an odour of camphor, b. p. 84—85°/9 mm., D_0^{0} 1·6441, D_0^{20} 1·6174. *Di-α-hydroxyisopropyl ketone,* $CO(CMe_2 \cdot OH)_2$, obtained by the action of aqueous potassium hydroxide on the dibromo-ketone, forms rhombic plates, m. p. 42—43°, b. p. 101·5—102°/11 mm., gives a *diacetyl* derivative, $C_{11}H_{18}O_5$, m. p. 51—52°, and is converted by magnesium methyl iodide and water into *pentamethylglycerol,*

$$OH \cdot CMe_2 \cdot CMe(OH) \cdot CMe_2 \cdot OH,$$

which crystallises in slender, shining needles or prisms, m. p. 118—119°. When heated with 2% sulphuric acid solution, the trihydric alcohol decomposes into acetone and methyl *iso*propyl ketone.

[With G. Briliant.]—The action of phosphorus pentabromide on *iso*propyl *tert.*-butyl ketone yields *α-bromoisopropyl* tert.-*butyl ketone,* $CMe_3 \cdot CO \cdot CMe_2Br$, b. p. 91—93°/40 mm., 62—64°/12 mm., D_0^{0} 1·2441, D_0^{20} 1·2233, which gives a good yield of Butlerov's oxoctenol (see above) when heated with 10% aqueous potassium hydroxide.

[With (Mlle.) A. Zacharova.]—iso*Propylisobutylcarbinol,*

$$CHMe_2 \cdot CH(OH) \cdot CH_2 \cdot CHMe_2,$$

obtained by the action of magnesium *iso*butyl bromide on *iso*but-aldehyde, has b. p. 156°, D_0^{0} 0·8325, D_0^{20} 0·8222, and on oxidation yields *iso*propyl *iso*butyl ketone, $CHMe_2 \cdot CO \cdot CH_2 \cdot CHMe_2$, b. p. 147—148°, D_0^{0} 0·82705, D_0^{20} 0·81223. *α-Bromoisopropyl* isobutyl ketone, $CMe_2Br \cdot CO \cdot CH_2 \cdot CHMe_2$, obtained by the action of either bromine or

phosphorus pentabromide, has b. p. 75—78°/12 mm., 81—85°/21 mm., D_0^0 1·2187, D_0^{2J} 1·1979, and, when heated with potassium formate and methyl alcohol in a sealed tube at 120°, yields iso*butyryldimethyl-carbinol*, OH·CMe$_2$·CO·CH$_2$·CHMe$_2$, b. p. 67—70°/13 mm., D_0^0 0·9159, D_0^{u0} 0·8962, the *semicarbazone* of which, $C_9H_{19}O_2N_3$, m. p. 126°, was prepared ; oxidation of the keto-alcohol gives valeric acid.* *a-Bromo-*iso*propyl a-bromo*iso*butyl ketone*, CMe$_2$Br·CO·CHBr·CHMe$_2$, b. p. 103—105°/21 mm., is also formed by the action of phosphorus pentabromide on *iso*propyl *iso*butyl ketone.

[With N. MANDRYK.]—*Phenyl*iso*propylcarbinol*, OH·CHPh·CHMe$_2$, prepared by the action of magnesium *iso*propyl⁵ iodide on benzalde-hyde, has b. p. 110—111°/13 mm., D_0^0 0·9933, D_{20}^{20} 0·9790, forms the *acetyl* derivative, $C_{12}H_{16}O_2$, b. p. 118—120°/16 mm., and on oxidation yields *phenyl* iso*propyl ketone*, CHMe$_2$·COPh, which is a colourless liquid, b. p. 95—98°/10 mm., D_0^0 0·9996, D_0^{20} 0·9848, and forms the *semicarbazone*, $C_{11}H_{15}ON_3$, m. p. 166—167°. The action of phosphorus pentabromide on the ketone yields phenyl a-bromo*iso*propyl ketone, b. p. 129—130°/12 mm., D_0^0 1·3845, D_{20}^{20} 1·3652 (compare Collet, A., 1898, i, 477). *Benzoyldimethylcarbinol*, CMe$_2$Bz·OH, b. p. 116—118°/9 mm., D_0^0 1·0928, D_{20}^{20} 1·0775, when kept in a sealed tube for some months, forms the *compound*, CMe$_2$Bz·O·CMe$_2$Bz or

$$\underset{CMe_2}{\overset{O}{>}}CPh·O·CPh\underset{CMe_2}{\overset{O}{<}},$$
m. p. 185—186°.

[With (Mlle.) L. KOLOTOVA.]—The action of phosphorus penta-bromide on *cyclo*hexyl methyl ketone yields *bromocyclohexyl methyl ketone*, CBrAc$\underset{CH_2·CH_2}{\overset{CH_2·CH_2}{<}}CH_2$, b. p. 97—101°/13 mm., and this, with heated with aqueous potassium hydroxide, gives 1-*acetyl-cyclohexan-1-ol*, C_6H_{10}Ac·OH, b. p. 92—94°/18 mm., D_0^0 1·04259, D_0^{20} 1·02569, which forms the *semicarbazone*, $C_9H_{17}O_2N_3$, m. p. 102° (decomp.), but does not yield a phenylosazone or react with Fehling's solution. On oxidation, 1-acetyl*cyclo*hexan-1-ol yields *cyclo*hexanone and acetic acid.

[With M. CHARITONOVA.]—The action of phosphorus pentabromide on *cyclo*hexyl *iso*propyl *ketone*, C_6H_{11}·CO·CHMe$_2$, b. p. 83°/11 mm., which was prepared from magnesium *cyclo*hexyl bromide and *iso*but-aldehyde, yields *cyclohexyl a-bromoisopropyl ketone*, C_6H_{11}·CO·CMe$_2$Br, b. p. 111—112°/10 mm., m. p. 29°. On oxidation, the latter gives *cyclohexyl a-hydroxyisopropyl ketone*, C_6H_{11}·CO·CMe$_2$·OH, b. p. 97—98°/11 mm., D_0^0 0·9764, D_0^{20} 0·9655, the *semicarbazide* of which, $C_{11}H_{21}O_3N_3$, m. p. 183°, was prepared. Oxidation of the keto-alcohol yields hexahydrobenzoic and acetic acids.   T. H. P.

Sugar Solutions and Calcium Hydroxide. P. J. H. VAN GINNEKEN (*Zeitsch. ver. deut. Zuckerind*, 1912, 1293—1295).—Polemical. A reply to the criticisms of Weisberg (A., 1912, i, 608).   E. F. A.

Photolysis of Sucrose by Ultra-violet Rays. DANIEL BERTHELOT and HENRI GAUDECHON (*Compt. rend.*, 1912, 155, 1016—1018. Compare A., 1910, ii, 813, 814; 1912, i, 750).—Working with rays ($\lambda = 0\cdot25\mu$)

the photolysis of sucrose can be shown to take place in two stages, the first, lasting six hours and consisting of hydrolysis of the sucrose to dextrose and lævulose, the solution remaining neutral, and no gas being evolved; and the second, of the decomposition of these two hexoses with the evolution of carbon monoxide and hydrogen, the relative volumes of these gases liberated pointing to the more rapid decomposition of the lævulose than the dextrose. With the extreme ultra-violet rays the first stage is very rapid, and the separation of the two phases is somewhat difficult. W. G.

Composition of Press Cakes from Sugar Refineries. Léon Lindet and Charpentier (*Bull. Soc. chim.*, 1912, [vi], 11, 956—958). —It is shown that these cakes, after having been properly washed by the slightly ammoniacal water produced by condensing steam from the evaporating pans, contain no free lime. The sugar, which can be extracted by washing them with water, is present in the free state. The cakes always contain insoluble tribasic calcium saccharate, owing to the fact that this compound is not decomposed in the customary rapid treatment with carbon dioxide. T. A. H.

Plant Colloids. II. The Stability of Starch Solutions. Max Samec (*Koll. Chem. Beihefte*, 1912, 4, 132—174. Compare A., 1912, ii, 144).—The ageing of starch solutions is accompanied by a very considerable reduction of the viscosity, and the influence of foreign substances on the changes which occur during the process of ageing has been investigated by means of viscosity measurements. The same starch was used for all the experiments, and the solutions prepared by mixing a weighed quantity of the starch to a paste with 25 c.c. of cold water and then adding the paste to 75 c.c. of boiling water. After boiling for one minute, the starch paste was heated for two hours at 120° and then filtered under pressure, the age of the starch solution being reckoned from the time of the completed filtration.

The rate of diminution of the viscosity of such starch solutions is greater for dilute than for more concentrated solutions. It is also greater for solutions which have been shaken than for corresponding solutions which have been kept undisturbed. The addition of hydrochloric acid diminishes the initial viscosity, but retards the further progress of the change, and thus increases the stability of the solutions. With increasing concentration of the acid, the influence on the stability increases at first and passes through a maximum. Potassium hydroxide raises the viscosity when added in very small quantity; if larger amounts are present the viscosity is diminished, however, and this effect is very pronounced in the case of solutions which contain alkali hydroxide in more than $0.001N$-concentration. Ammonium sulphate and ammonium thiocyanate both diminish the initial viscosity, but in concentrated solution the influence of the two salts on the stability of the starch solution is quite different, in that the sulphate increases the stability, whilst the thiocyanate is comparatively inactive.

The viscosity change is irreversible in character, and the sensitiveness of the starch solutions towards electrolytes diminishes with the time which has elapsed since their preparation. The ageing of the

solutions is also found to be accompanied by an increase in the electrical conductivity.

An explanation of some of the observed facts is suggested, in which the author assumes that the active constituent is a complex compound of starch and phosphoric acid.   H. M. D.

Photochemical Synthesis of Carbohydrates. JULIUS STOKLASA JOHANN ŠEBOR, and WENZEL ZDOBNICKÝ (*Biochem. Zeitsch.*, 1912, 47,. 186—188. Compare A., 1912, i, 606).—A reply to the criticisms of Walther Löb (A., 1912, i, 750).   S. B. S.

Existence of a Hydrate of Nitrocellulose. TH. CHANDELON (*Bull. Soc. chim. Belg.*, 1912, 26, 495—502).—The viscosities of solutions of dry and moist nitrocelluloses in mixtures of alcohol and ether have been examined, together with the viscosities of solutions of dry nitrocellulose in the same mixture to which small quantities of water have been added.

The author is led to the conclusions : (1) that the greater solubility of moist nitrocellulose in a mixture of alcohol and ether does not depend on the existence of a hydrate, but simply on the dilution of the solvent by the water contained in the moist substance ; (2) that it is im-material whether this water is contained in the moist nitrocellulose or previously added to the solvent, and (3) that a mixture of alcohol and ether which contains small quantities of water has a solvent action towards nitrocellulose superior to that of an anhydrous mixture of the two solvents.   H. W.

A New Nitrocellulose. TASSART (*Bull. Soc. chim.*, 1912, [iv], 11, 1009—1011).—By the successive action of sulphuric acid and nitric acid on cotton with avoidance of rise in temperature, the author has obtained a white, powdery unstable compound which is provision-ally termed α-nitrocellulose and which contains about 13·5% nitrogen. When heated on the water-bath it becomes pasty, evolves nitrous fumes with increasing intensity, and ultimately ignites. In thin layers, however, heating can be conducted without inflammation, when the residue, after cessation of evolution of nitrous fumes, is found to contain 6% nitrogen and to reduce Fehling's solution. The latter property is not possessed by α-nitrocellulose to any marked extent.

Certain substances, such as diphenylamine, dextrose, diaminophenol hydrochloride, α-naphthylamine, tetramethyldiaminobenzophenone, etc., when warmed with α-nitrocellulose on the water-bath cause darkening and subsequent charring without evolution of nitrous fumes or inflammation. On the other hand, the tendency of α-nitro-cellulose towards spontaneous inflammability is accentuated by the presence of p-phenylenediamine.

α-Nitrocellulose is insoluble in water, soluble in methyl and ethyl alcohols, aldehyde, and acetone. Treatment with water or aqueous sodium hydroxide leaves it unaffected, but alcoholic sodium hydroxide causes marked alteration in properties, and renders it completely soluble in water.

Dextrose and amidon, when similarly treated with sulphuric and nitric acids, yield similar products.   H. W.

Formylated Cellulose. EDWARD C. WORDEN (*J. Soc. Chem. Ind.*, 1912, **31**, 1064—1068).—The author discusses at some length the several methods of preparing cellulose acetates and formates which have been published, also the means which have been devised for converting these esters into plastic substances resembling celluloid.

Results of work carried out with the object of converting cellulose formate, obtained by the action of formic acid (99%) and zinc chloride on a cellulose prepared by denitrating nitro-cellulose with ammonium sulphide solution, into a modification having more valuable properties, such as greater solubility in common organic solvents, are recorded.

The crude solutions of cellulose formate as obtained directly from the cellulose were treated with small quantities of water for varying periods. Generally speaking, the effect of this treatment is to increase the solubility of the product in solvents such as acetone, chloroform, and tetrachloroethane, the solubility becoming greater as the proportion of water employed or the period of treatment is increased. W. H. G.

Neurine Bromide. ERNST SCHMIDT and A. SEEBERG (*Apoth. Zeit.*, 1912, **71**; Reprint, 2 pp.).—The conversion of large quantities of trimethylbromoethylammonium bromide into neurine by moist silver oxide is often accompanied by serious loss, due to the formation of trimethylamine. A cheaper and more satisfactory method is described, in which barium hydroxide is used in place of silver oxide.

Neurine bromide on heating with hydrobromic acid at 165—170° gives, as already observed, trimethyl-β-bromoethylammonium bromide, but the mother liquors contain another substance, apparently the isomeric *trimethyl-a-bromoethylammonium bromide*, crystallising in tablets. D. F. T.

The Asymmetric Cobalt Atom. VI. ALFRED WERNER and McCUTCHEON (*Ber.*, 1912, **45**, 3281—3287).—The active compounds of cobalt which have hitherto been prepared belonging to the series $[en_2CoX_2]X$ contain two monobasic acid residues in direct combination with the cobalt atom, for example, $[Cl_2Co\ en_2]X$ and $[(NO_2)_2Co\ en_2]X$. The authors have now investigated the compounds in which the two X-groups have been replaced by one dibasic acid residue, for example, the oxalic and carbonic acid residues, in order to see if they show mirror-image isomerism. These compounds have

the following structural formulæ : $\left[\begin{matrix} O:C\cdot O \\ O:C\cdot O \end{matrix}\!\!>\!Co\ en_2\right]X$ and

$$\left[O:C\!\!<^O_O\!\!>\!Co\ en_2\right]X.$$
It has been shown previously (A., 1912, i, 78) that geometrical isomerides do not exist, and that the acid residues occupy neighbouring co-ordination positions. Optical isomerides should, however, exist in accordance with the following scheme :
It was not found possible to resolve the inactive compounds into their active components, but the individual isomerides have been obtained directly from the active 1:2-dichlorodiethylenediaminecobaltic salts by the action of potassium carbonate and oxalate respectively, for example : $[Cl_2Co\ en_2]Cl + K_2CO_3 = [CO_3Co\ en_2]Cl + 2KCl$. The fact that such active isomerides have been prepared forms further support for the *cis*-structure of these compounds.

The active carbonato-salts possess an intense red colour, so that their rotatory power could only be determined for red light (C line). The observed specific rotations are fairly large, for example, the chloride has $[a]_c \pm 350°$, and it is noteworthy that the various salts show very different rotatory powers, the iodide having $[a]_c \pm 250°$ and the dithionate $[a]_c \pm 216°$. In cold aqueous solution the salts are fairly stable, undergoing racemisation very slowly, the rotation diminishing by one-half in about eight days. At 90° racemisation is complete in a short time. The products of racemisation consist of the inactive carbonato-salts, and are formed probably by one of the valencies of the carbonato-residue becoming loosened for a time, the radicle $[Co\ en_2]$ then undergoing a structural change.

The oxalo-salts possess a smaller specific rotation than the carbonato-salts, the chloride and nitrate having $[a]_c \pm 200°$ and the iodide $[a]_c \pm 160°$. They are quite stable, the aqueous solutions showing no tendency to racemise even on warming.

The sign of rotation of the various carbonato- and oxalo-salts is the opposite to that of the dichloro-salts from which they are obtained.

Carbonato-salts, YX, where $Y = [CO_3Co\ en_2]$.—The d- and l-*chlorides*, YCl, are obtained by heating a mixture of 1 gram of the active dichloro-chloride with the calculated quantity of potassium carbonate and 0·5 c.c. of water on the water-bath until the colour changes to red (2 mins.) The reaction product is then rapidly cooled in a freezing mixture and rubbed with a platinum spatula, when the chloride separates as a red, crystalline powder, forming a mixture of the active and racemic compounds. The racemate is less soluble than the active salt, and is left undissolved when sufficient water is added to dissolve about three-quarters of the solid. The pure active chloride is then obtained from the aqueous solution by precipitation with a mixture of alcohol and ether. $[a]_c \pm 350°$, $[M]_c \pm 960°$; 100 c.c. of water dissolve 5 grams of the active chloride at 18°.

The active *iodides*, YI, and *dithionates*, $Y_2S_2O_6$, were obtained from the active chlorides by double decomposition with ammonium iodide and sodium dithionate respectively. The former have $[a]_c \pm 250°$, $[M]_c \pm 915°$, and dissolve to the extent of 1 gram in 100 c.c. of water at 18°; the latter has $[a]_c + 216°$ and $- 220°$, $[M]_c + 689°$ and $- 702°$, the solubility being 3·5 grams of the salt in 100 c.c. of water at 18°.

Oxalo-salts, YX, where $Y = [C_2O_4Co\ en_2]$.—The active *chlorides*, YCl,H$_2$O, are prepared similarly to the carbonato-salts, using potassium oxalate, the chief difference being that the racemate is more soluble than the active salt, the latter separating out fairly pure. $[a]_c + 200°$ and $- 204°$, $[M]_c + 641°$ and $- 653°$; 100 c.c. of water

dissolve 2 grams of the salt at 18°. The active *iodides*, YI, and *nitrates*, YNO_3,H_2O, were obtained from the chloride by double decomposition with ammonium iodide and silver nitrate respectively. Their solubilities are respectively 1 gram and 4 grams in 100 c.c. of water at 18°. The former have $[a]_c + 160°$ and $- 155°$, $[M]_c + 630°$ and $- 610°$, the latter having $[a]_c + 204°$ and $- 200°$, $[M]_c + 689°$ and $- 676°$.

<div align="right">T. S. P.</div>

The Asymmetric Cobalt Atom. VII. ALFRED WERNER and YUJI SHIBATA (*Ber.*, 1912, **45**, 3287—3293).—Optically active 1 : 2-diamminediethylenediaminecobaltic salts have now been obtained. They could not be prepared by resolution of the racemates, but were obtained from the active 1 : 2-bromoammine salts by the action of liquid ammonia, in accordance with the equation : $\begin{bmatrix} Br \\ NH_3 \end{bmatrix} Co\ en_2 \Big] X_2 + NH_3 =$ $\begin{bmatrix} NH_3 \\ NH_3 \end{bmatrix} Co\ en_2 \Big] \begin{matrix} X_2 \\ Br \end{matrix}$. This reaction denotes a change from an asymmetric cobalt compound to one showing molecular asymmetry I (compare A., 1911, i, 839).

1 : 2-Bromoamminediethylenediaminecobaltic bromide was used in the first experiments, but it was found that the active 1 : 2-diammine bromide obtained was always contaminated with the inactive 1 : 6-salt. The formation of the 1 : 6-isomeride was completely prevented, however, when the bromocamphorsulphonate was used instead of the bromide Recrystallisation of the product of the action of liquid ammonia on 1 : 2-bromoamminediethylenediaminecobaltic *d*-bromocamphorsulphonate gives immediately pure d-*diamminediethylenediaminecobaltic* d-*bromocamphorsulphonate*.

The active salts show very marked dispersion of the rotation, for example, the chloride has $[a]_c \pm 15°$, $[a]_D \pm 50°$; in the three-field polarimeter the *d*-salts give a yellow middle field and orange outer fields, the colours being reversed for the *l*-salts. Their rotatory powers for the *D*-line agree approximately with those of the dinitro-salts, and are about one-third of the values obtained for the triethylenediamine salts for both the *C*- and *D*-lines.

The solubilities of the active salts are, as a rule, greater than that of the racemate. Of the bromocamphorsulphonates, the *dd*- and *ll*-salts are sparingly soluble, whilst the *dl*- and *ld*-salts are easily soluble.

The cold aqueous solutions of the active salts can be preserved indefinitely without undergoing racemisation; on boiling for some time, racemisation occurs, being accompanied by a complete decomposition of the compounds.

d-*Diamminediethylenediaminecobaltic* d-*bromocamphorsulphonate* and the corresponding *ll*-*salt* were obtained by dissolving *d*-bromoamminediethylenediaminecobaltic *d*-bromocamphorsulphonate or the corresponding *ll*-salt in liquid ammonia. After a short time the solution turns yellow, and one recrystallisation of the residue after allowing the ammonia to evaporate gives the pure salt, $[a]_D^{24} + 81°$ and $- 80°$.

The following active diamminediethylenediaminecobaltic salts, YX_3,

where $Y = [(NH_3)_2Co\ en_2]$, were obtained from the active bromo-camphorsulphonates by treatment with concentrated solutions of the appropriate acids. The *chlorides*, YCl_3, form golden-yellow prisms ; the *bromides*, YBr_3, crystallise in deep-yellow needles ; the *perchlorates*, $Y(ClO_4)_3$, form yellow, prismatic crystals, and the *nitrates*, $Y(NO_3)_3$, give slender, golden-yellow, flat crystals. The *iodides*, YI_3, dark yellow crystals, and the *dithionates*, $Y(S_2O_6)_3,3\cdot5H_2O$, small, cubical crystals, are obtained from the bromides by double decomposition with ammonium iodide and sodium dithionate respectively ; the nitrate can similarly be obtained, using silver nitrate.

The specific and molecular rotations of the various salts are shown in the following table :

	$[\alpha]_D.$	$[M]_D.$	$[\alpha]_C.$	$[M]_C.$	Temp.

T. S. P.

The Asymmetric Cobalt Atom. VIII. ALFRED WERNER and G. TSCHERNOV (*Ber.*, 1912, **45**, 3294—3301).—Optically active 1:2-chloro-bromodiethylenediaminecobaltic salts, $\left[\begin{matrix}Cl\\Br\end{matrix}Co\ en_2\right]X$, are described.

The inactive 1:2-chlorobromo-bromide, which was used as the starting point, was obtained as follows : 1:6-dichlorodiethylenediaminecobaltic chloride (compare A., 1912, i, 82) was prepared, and transformed into 1:2-chloroaquodiethylenediaminecobaltic sulphate. From the latter, chloroaquodiethylenediaminecobaltic bromide was obtained and transformed, by heating at 105°, into a mixture of the 1:2- and 1:6-chloro-bromodiethylenediaminecobaltic bromide, from which the 1:2-isomeride is obtained by means of its lesser solubility (compare A., 1912, i, 83).

The active chlorobromo-salts were obtained by treating an aqueous solution of the racemic bromide with active ammonium bromocamphor-sulphonate (compare the preparation of the active dichloro-salts, A., 1912, i, 11). After a short time, when ammonium *d*-bromo-camphorsulphonate is used, a microcrystalline precipitate of *l*-chloro-bromodiethylenediaminecobaltic *d*-bromocamphorsulphonate separates, whereas ammonium *l*-bromocamphorsulphonate gives the *dl*-salt. The salts are very unstable in aqueous solution, readily giving the bromo-aquo-salts, so that all operations must be carried out as quickly as possible.

The various active salts were obtained from the bromocamphor-sulphonates by trituration with the requisite concentrated mineral acid until complete solution was attained ; the strongly-cooled solutions were then precipitated with alcohol.

The following table (rows 1 and 2) gives a summary of the rotatory powers of the various salts ; for the sake of comparison, the rotations of the dichloro-salts are also given (rows 3 and 4) :

	Chloride.		Bromide.		Nitrate.		Sulphate.		Dithionate.	
	$[a]$.	$[M]$.	$[a]$.	$[M]$.	$[a]$.	$[M]$.	$[a]$.	$[M]/2$.	$[a]$.	$[M]/2$.
d-Salt...	$+164°$	$+571°$	$+148°$	$+531°$	$+144°$	$+513°$	$+144°$	$+506°$	$+116°$	$+445°$
l-Salt..	-176	-612	-155	-608	-152	-542	$-148°$	-520	-120	-460
d-Salt...	$+184$	$+558$	$+168$	$+554$	$+164$	$+511$	$+180$	$+536$	$+160$	$+542$
l-Salt...	-200	-607	-176	-581	-164	-511	-182	$-540·5$	-164	-556

The above are the maximum values observed, since racemisation takes place very rapidly.

l-*Chlorobromodiethylenediaminecobaltic* d-*bromocamphorsulphonate*,

$$Y(SO_3 \cdot C_{10}H_{14}OBr),$$

where $Y = \begin{bmatrix} Cl \\ Br \end{bmatrix} Co\ en_2$, forms a grey, crystalline powder with a violet shade ; $[a]^{20} - 40°$, $[M]^{20} - 242°$. The corresponding ' dl-*salt* is similar ; $[a]^{20} + 32°$, $[M]^{20} + 193°$. The active *chlorobromodiethylenediaminecobaltic chlorides*, YCl,H_2O, are dark, greyish-violet, crystalline powders, as also are the *bromides*, YBr,H_2O, and the *nitrates*, YNO_3. The *sulphates*, Y_2SO_4,H_2O, and *dithionates*, $Y_2S_2O_6,H_2O$, are respectively light violet, crystalline powders and light grey leaflets. T. S. P.

a-Aminobutyric Acid and its Derivatives. EMIL ABDERHALDEN and ERICH WURM (*Zeitsch. physiol. Chem.*, 1912, **82**, 167—171. Compare Abderhalden and Chang, A., 1912, i, 338).—When pure a-aminobutyric acid is treated with concentrated hydrochloric acid under the conditions prevailing during protein hydrolysis, only about 5% of the acid undergoes decomposition. Alanine and leucine remain unchanged under these conditions.

The conditions for the preparation of pure formyl-*d*- and -*l*-aminobutyric acid are described. Formyl-*d*-aminobutyric acid has $[a]_D^{20} - 27·74°$, the value for the isomeride being $+27·98°$.

The formyl group is readily hydrolysed by water.

On feeding *dl*-aminobutyric acid or glycyl-*dl*-aminobutyric acid to rabbits, neither the acids nor their components could be detected in the urine. E. F. A.

Preparation of Creatine from Urine. ALOIS VIQUERAT (D.R.-P. 251937).—A modification of Neubauer's method (compare Abderhalden, *Lehrbuch Biochem. Arbeitsmethoden*, 1910, III, 783) by which creatine is isolated from urine as its zinc chloride double salt. F. M. G. M.

Some Complex Compounds of Platinous Chloride with Aminoacetal. J. TSCHUGAEV and B. ORELKINE (*Compt. rend.*, 1912, **155**, 1021—1023).—An endeavour to prepare two isomeric substances of the type, $[Pt(NHMe_2)_2Cl_2]$, prepared by Jörgensen (A., 1906, i, 338), replacing the dimethylamine by aminoacetal. On adding aminoacetal to a dilute solution of potassium platinosochloride, a yellow, crystalline compound is deposited, crystallising from alcohol in needles,

m. p. 133°. It has the composition (Pt2ACl$_2$), where A stands for tho aminoacetal molecule, NH$_2$·CH$_2$·CH(OEt)$_2$. This substance is a very feeble electrolyte, and is almost unacted on by silver nitrate in alcoholic solution. In benzene solution it polymerises as shown by cryoscopic molecular weight determinations. The mother liquors from its preparation on evaporation yield a colourless, crystalline *compound*, (Pt4A)Cl$_2$, m. p. 130 5°, the chlorine of which is immediately precipitated by silver nitrate. With potassium platinosochloride it yields a *salt*, (Pt4A)PtCl$_4$, pink needles, m. p. 127°, which is not acted on by Reiset's chloride I.

An attempt was made to prepare the two isomerides having the constitution (Pt2A2NH$_3$)Cl$_2$, but it only yielded gummy products which with potassium platinosochloride gave the same *salt*,

$$(\text{Pt2A2NH}_3)\text{PtCl}_4,$$

lilac needles, m. p. 151°. W. G.

The Nitrile and Sulphonamide of Thiodiacetic Acid. NILS VON ZWEIGBERGK (*Ber.*, 1912, **45**, 3337—3338).—Dry hydrogen sulphide and ammonia are led into an ethereal solution of chloroacetonitrile until the solution, which first becomes warm, begins to cool. After collecting the precipitated ammonium chloride and concentrating the filtrate, white, rhombic tablets of the *nitrile* of thiodiacetic acid, S(CH$_2$·CN)$_2$, are obtained, m. p. 45·5—46·5°. Acetone may be used instead of ether as solvent. The substance cannot be obtained by the action of phosphoric oxide on ammonium thiodiacetate.

If, instead of proceeding as above, an ammoniacal, alcoholic solution of chloroacetonitrile is saturated with hydrogen sulphide, yellowish-white leaflets of the *sulphonamide* of thiodiacetic acid, S(CH$_2$·CS·NH$_2$)$_2$, m. p. 124—125°, are obtained. T. S. P.

Constitution of the Compound known as Phorononitrile, and on Some Other Derivatives of Phoronic and Mesitylic Acids. J. MILIKAN (*Rec. trav. chim.*, 1912, **31**, 287—298).—The true nitrile of phoronic acid should have the formula C$_{11}$H$_{16}$ON$_2$, whereas the so-called nitrile discovered by Pinner (A., 1881, 790) has the formula C$_{11}$H$_{18}$O$_2$N$_2$. Applying the conclusions drawn by Anschütz in the case of mesitonic acid (A., 1888, 1272) to the present question, the relation of these nitriles to phorone should be represented thus : Phorone, CMe$_2$:CH·CO·CH:CMe$_2$. Nitrile, CN·CMe$_2$·CH$_2$·CO·CH$_2$·CMe$_2$·CN. Amide,

$$\text{NH}_2\text{·CO·CMe}_2\text{·CH}_2\text{·CO·CH}_2\text{·CMe}_2\text{·CO·NH}_2.$$
$$\text{CMe}_2\text{·CH}_2\text{·C·CH}_2\text{·CMe}_2.$$

So-called nitrile,

$$\text{CO——NH NH-CO}$$
As the direct addition of hydrogen cyanide to such an unsaturated ketone as phorone would be extremely difficult, an attempt has been made to prepare the amide. *Methyl phoronate*, C$_{13}$H$_{22}$O$_5$, obtained in white needles, m. p. 30°, by the action of methyl alcohol and sulphuric acid on phoronic acid, was heated for some hours with alcoholic ammonia in a sealed tube, when, instead of the expected amide, the so-called phorononitrile was the product, m. p. 326—327°.

As the amide group is in the favourable γ position with respect to the ketone group, it is assumed that the expected amide has lost water and that the phorononitrile is a di-lactam or an anhydrodiamide of the above constitution. It is possible to replace the hydrogen attached to the nitrogen in compounds of this structure, and, in fact, *diacetylanhydrophoronodiamide*, $C_{15}H_{22}O_4N_2$, m. p. 89—90°, has been obtained by the action of acetic anhydride. The compound is also very stable and dissolves in cold concentrated nitric acid, yielding a crystalline mass which is probably an additive product with the acid, and from which, water recovers the material unchanged.

Analogous anhydrodiamides are the imidopimelimide of Marckwald (A., 1888, 677; compare also Volhard, A., 1892, 433) and the ketodi-imide of β-acetylglutaric acid of Emery (A., 1897, i, 325).

Pinner's phoronimide (*loc. cit.*) also yields the anhydrodiamide on heating with ammonia, and, accepting Anschütz's di-lactone structure for the parent substance phoronic anhydride, it is probable that the imide is a lactone-anhydroamide of the constitution

$$CMe_2 \cdot CH_2 \cdot C \cdot CH_2 - CMe_2$$

$$CO - NH \; O - CO.$$
Methyl phoronate and the di-lactone have also been heated with methylamine, the product being *anhydrophoronodimethyldiamide*, $C_{13}H_{22}O_2N_2$, m. p. 136—137°, which is much less stable than the unsubstituted anhydrodiamide, since it readily loses methylamine on warming with potassium hydroxide. The *product* of the action of methylamine on the di-lactone in the cold has the formula $C_{13}H_{26}O_4N_2$ and m. p. 116—118°, and from analogy to the fact that ammonia forms with hydrochelidonodi-lactone (Volhard, *loc. cit.*) and with β-acetylglutarodilactone (Emery, *loc. cit.*) ammonium salts of amino-acids, it probably has the constitution

$$CMe_2 \cdot CH_2 \cdot CO \cdot CH_2 \cdot CMe_2$$
$$OC \cdot NHMe \qquad OC \cdot OH, NH_2Me.$$
It decomposes at its melting point, and the *product*, $C_{12}H_{19}O_3N$, m. p. 110°, is, most likely, the lactone of anhydrophoronomethylamide,

$$CMe_2 \cdot CH_2 \cdot C \cdot CH_2 \cdot CMe_2$$

$$OC - NMe \; O - CO.$$
Methyl mesitylate, $C_9H_{15}O_3N$, has also been prepared in colourless needles, m. p. 119—120°.   J. C. W.

The Formation of Metallic Nitrides from Thiocyanates and Cyanides. ALEXANDER C. VOURNASOS (*Zeitsch. anorg. Chem.*, 1912, 77, 191—196. Compare A., 1911, ii, 600).—Aluminium, in the form of an impalpable powder, reduces many organic nitrogen compounds, with formation of the nitride; thus, with thiocarbamide, the reaction is $CS(NH_2)_2 + 2Al = Al_2N_2 + H_2S + H_2 + C$.

Potassium and ammonium thiocyanates, dried and mixed with aluminium powder, react if placed in a covered crucible and heated by the blowpipe according to the equation : $2K \, CNS + 2Al = {}_2S_2 + Al_2N_2 + 2C$, but a secondary reaction occurs to some extent between

the aluminium nitride, carbon, and potassium sulphide : $2K_2S +$ $Al_2N_2 + 2C = Al_2S_3 + 2KCN + K_2S$. Washing the product with alcohol gives a residue consisting of aluminium and carbon. Boron reacts in a similar manner.

Magnesium reacts violently with thiocyanates, more quietly with cyanides : $2KCN + 3Mg = Mg_3N_2 + 2K + 2C$, the product containing free potassium, whilst some carbide is formed at higher temperatures.

Glucinum reacts quantitatively with cyanides : $3Gl + Hg(CN)_2 =$ $Gl_3N_2 + Hg + 2C$, and calcium reacts in a similar manner.   C. H. D.

The Supposed Case of Isomerism with Potassium Ferricyanide. Otto Hauser and E. Biesalski (*Ber.*, 1912, 45, 3516—3521).—The supposed green isomeride of potassium ferricyanide (compare Locke and Edwards, A., 1899, i, 407 ; Bellucci and Sabatini, A., 1911, i, 430) is simply the ordinary salt containing some Prussian-blue as impurity ; the aqueous solution contains the Prussian-blue in collodial solution. An artificial mixture of potassium ferricyanide and Prussian-blue answers to all the reactions of the supposed green isomeride, and gives the same absorption and ultramicroscopic phenomena. The non-formation of the ferri-imido-ester (compare Bellucci and Sabatini, *loc. cit.*) from the green isomeride, or at all events its formation to a limited extent, is due to the catalytic effects of the decomposition product.

The above agrees with Piutti's observation (A., 1912, ii, 712) that the red and green forms have exactly the same absorption spectrum.
                                                                T. S. P.

Complex Compounds of Iron and the Formation of Nitroprusside. Paul Schwarzkopf (*Abhandl. deut. naturwiss-med. Ver. Böhmen*, 1911, 3 ; Reprint 55 pp.) —The assumption that the formation of nitroprusside occurs accoıding to two consecutive reversible reactions :
$$K_4FeCy_6 + NaNO_2 \rightleftharpoons K_3Na(FeCy_5NO_2) + KCN \text{ and}$$
$$K_3Na(FeCy_5NO_2) + H_2O \rightleftharpoons K_2(FeCy_5NO) + KOH + NaOH$$
has been tested by titrimetric estimation of the alkali present after equilibrium is reached, and the results when substituted into an equation derived to represent the conditions of the equilibrium, yield good constants. Considering the reactions from the ionic point of view, $(FeCy_6)''' +$ $(NO_2') \rightleftharpoons (FeCy_5NO_2)'' + Cy'$ and $(FeCy_5NO_2)''' + H_2O \rightleftharpoons$ $(FeCy_5NO)'' + 2OH''$, the first stage seems to imply a dissociation of the ferrocyanide ion into $(FeCy_5)'''$ and Cy' ; this is quite probable as mercuric chloride in not too dilute solution of potassium ferrocyanide precipitates an iron ferrocyanide apparently indicative of a series of dissociations finally reaching the ferrous ion ; similarly formaldehyde which is well known to combine with hydrocyanic acid, acts on a warm solution of potassium ferrocyanide, forming a deposit consisting of a mixture of ferrous and ferric hydroxides with a complex ferrocyanide. The power of mercuric chloride to remove cyanide ions from a solution should therefore accelerate the formation of nitroprusside by withdrawing the cyanide ion produced in the first stage of the action, and experimental investigation shows that it effects a very
considerable acceleration. It was not found possible to prepare compounds in which more than one (CN) group of potassium ferrocyanide is replaced by (NO).

It is also discovered that nitrous acid exerts an incomplete oxidising action on an acidic solution of potassium ferrocyanide and an incomplete reducing action on acidic solutions of potassium ferricyanide ; in a similar manner it causes the oxidation of an ordinary ferrous salt and the reduction of a ferric one.   D. F. T.

Preparation and Properties of Scandium Platinocyanide. N. A. ORLOV (*Chem. Zeit.*, 1912, 36, 1407—1408).—The compounds of scandium which have hitherto been obtained leave it doubtful whether scandium must be classed with the cerium group or with the yttrium group of the rare earths.   The double sulphate with potassium sulphate resembles the double sulphates of the cerium metals, whilst the weak basic properties of scandium, and the fact that copious precipitates are obtained when the salts are boiled with solutions of sodium thiosulphate or hydrofluosilicic acid, indicates its resemblance to the yttrium metals.   The platinocyanides of the cerium metals are yellow, whilst those of the yttrium metals are red, and this should give a method of classifying scandium.   Scandium platinocyanide was obtained by concentrating the solution obtained after collecting the precipitate of barium sulphate formed on mixing equivalent solutions of scandium sulphate and barium platinocyanide.   Yellow crystals, which are very similar in appearance to cerium platinocyanide, separate from the solution, but a red, crystalline crust forms on the sides of the vessel.   On drying, the yellow crystals become reddish- or orange-coloured.   If the solution is evaporated to dryness on the water-bath a yellow residue is obtained, which becomes red on cooling.   The reverse 'change from red to yellow takes place on heating.   The yellow crystals have a composition corresponding with the formula $Sc_2(PtC_4N_4)_3,18H_2O$, whilst the red crystals have the formula
$$Sc_2(PtC_4N_4)_3,21H_2O.$$ T. S. P.

Some Metallic Salts and Complex Metallic Derivatives of Cyano-carboxylic Acids and their Esters.   LIZZIE PETTERSON (*J. pr. Chem.*, 1912, [ii], 86, 458—471).—An account of the preparation and properties of some metallic salts and derivatives of cyanoacetic and α-cyanopropionic acids.

By triturating cuprous oxide with a hot concentrated aqueous solution of cyanoacetic acid in the absence of air, a *cuprous* salt,

$$CN \cdot CH_2 \cdot CO_2Cu,3CN \cdot CH_2 \cdot CO_2H,H_2O$$
is obtained in small, white needles, which become green and melt at 119—120° when rapidly heated.

The *ferric* salt, $Fe_3(CO_2 \cdot CH_2 \cdot CN)_7(OH)_2,6H_2O$, prepared by the addition of ferric sulphate to a solution of barium cyanoacetate, forms deep, garnet-red prisms, m. p. 107° ; the *cobalt, cupric*, and *silver* salts are also mentioned.

Hydroxymercuricyanoacetic acid, $OH \cdot Hg \cdot CH(CN) \cdot CO_2H$, is obtained as a white, crystalline precipitate by shaking mercuric oxide for two days with an aqueous solution of cyanoacetic acid ; the *sodium* and

barium salts are prepared in a similar manner from the corresponding salts of cyanoacetic acid ; the *potassium* salt is prepared by the addition of potassium hydroxide to an aqueous solution of mercuric cyanide and potassium cyanoacetate.

The *methyl* and *ethyl* esters are formed by the interaction of mercuric acetate and the corresponding esters of cyanoacetic acid in methyl alcoholic solution.

Mercuric acetate reacts with ammonium cyanoacetate in aqueous solution, yielding the *compound*, $O{<}^{Hg\cdot CH(CN)\cdot CO_2}_{Hg\cdot CH(CN)\cdot CO_2}{>}Hg$, as a white, flocculent precipitate.

α-Hydroxymercuri-α-cyanopropionic acid, $OH\cdot Hg\cdot CMe(CN)\cdot CO_2H$, is a yellowish-white, crystalline substance obtained by the addition of α-cyanopropionic acid to a solution of mercuric oxide in excess of dilute acetic acid.   F. B.

The Benzene Problem. KURT GEBHARD (*J. pr. Chem.*, 1912, [ii], **86**, 540—545).—A repetition of the author's views on the structure of the benzene ring (A., 1912, ii, 242), together with a criticism of a recent paper by Liebig on this subject (A., 1912, i, 686).   F. B.

Chemical Action of Light. III. Oxidation of Benzene Hydrocarbons. HERMANN SUIDA (*Monatsh.*, 1912, **33**, 1255—1285). —The fact that the most easily isolable products of the autoxidation in light of benzene homologues are carboxy-acids is attributed to the relative instability of the intermediate products.

The most satisfactory source of light used was a quartz lamp, used at a distance of about 10 centimetres from the specimen of substance. The velocity of the first stage of the oxidation could be approximately measured by the amount of peroxide formation ; this was estimated by the action on a solution of potassium iodide acidified with dilute sulphuric acid with titration of the liberated iodine some hours afterwards. The parallel formation of carboxylic acids was estimated previously by titration with $N/30$-potassium hydroxide solution ; it appears that the amount of acid formed cannot be entirely due to the decomposition of the peroxide.

The results indicate that pure benzene is practically passive, but that the presence of thiophen causes peroxide formation. Methyl substituted benzenes undergo autoxidation when illuminated, and the action is accelerated by the presence of small quantities of nitrobenzene or of one of the nitrotoluenes. The oxidation of xylene occurs more than twice as rapidly as that of the toluenes, and *p*-xylene oxidises more rapidly than the ortho-isomeride. The oxidation of 4-nitro-*m*-xylene under the influence of light resembles that of *p*-nitrotoluene, but is feebler ; this accords with the behaviour of these substances towards chromic acid ; *p*- and *o*-nitrotoluenes are oxidisable by this reagent to the corresponding aldehydes, but 4-nitro-*m*-xylene in acetic anhydride solution containing sulphuric acid is oxidised, according to the conditions, to 4-*nitro*-m-*tolualdehyde*, small, yellow rods, m. p. 64° (*phenylhydrazone*, m. p. 108°), or the corresponding *diacetate*,

$NO_2 \cdot C_6H_3Me \cdot CH(OAc)_2$, yellow needles, m. p. 80—82°, together with some 4-nitro-m-toluic acid, m. p. 219—220°.

The results are discussed in relation to their theoretical bearing.

D. F. T.

Rational Preparation of Benzene Homologues. FRANZ KUNCKELL and GEORG ULEX (*J. pr. Chem.*, 1912, [ii], 86, 518—520. Compare Rennie, T., 1881, 41, 33).—In the preparation of the homologues of benzene by the Friedel-Craft reaction, the alkyl haloids may be replaced with advantage by the esters of chlorocarbonic acid.

When aluminium chloride is added to a mixture of the aromatic hydrocarbon and chloro-ester, several alkyl groups are simultaneously introduced, whilst if the ester is added to a cooled mixture of the hydrocarbon and aluminium chloride, the main product consists of a hydrocarbon in which only one alkyl group has been substituted.

The preparation of toluene and xylene from methyl chlorocarbonate and benzene, of trimethylbenzene from toluene, and of diethylbenzene and diethyltoluene, is described.

The *iso*butyl and amyl esters of chlorocarbonic acid give better yields than the lower homologues. F. B.

a-Phenyl-$\beta\beta$-dimethylpropane, a New Amylbenzene. ARTUR BYGDÉN (*Ber.*, 1912, 45, 3479—3483).—The interaction of magnesium benzyl chloride and *tert.*-butyl bromide in boiling ether leads to the formation of *a-phenyl-$\beta\beta$-dimethylpropane*, $CMe_3 \cdot CH_2Ph$, b. p. 185·6—186·0°, $D_4^{18\cdot5}$ 0·8581, $n_D^{18\cdot5}$ 1·48837, a colourless liquid having a pleasant, aromatic odour resembling that of anisole. C. S.

Influence of Light on the Rate of Polymerisation of Phenylbutadiene. HANS STOBBE and FRITZ REUSS (*Ber.*, 1912, 45, 3496—3498).—The formation of bisphenylbutadiene by different methods has been recorded by several investigators. The authors have performed parallel experiments, in darkness and in ordinary daylight, on phenylbutadiene in an atmosphere of carbon dioxide. The course of the polymerisation is followed by measuring the change in the refractive index It is found that the polymerisation proceeds in the dark, but is considerably accelerated by light. Assuming that the quantity of the bimolecular form is proportional to the refractive index, the unexposed hydrocarbon contains 12—13% of bisphenylbutadiene and the insolated specimen 75—76%, after two and a-half months. The polymerisation appears to be complete after seven months. C. S.

Action of Aniline on 1:3:5-Tribromo-2:4:6-tri-iodobenzene. CONSTANTIN I. ISTRATI and M. A. MIHAILESCU (*Chem. Zentr.*, 1912, ii, 1275; from *Bul. Soc. Ştiinţe Bucareşti*, 1912, 21, 23—26).—When this tribromotri-iodobenzene is heated with aniline it undergoes more extensive substitution than is the case with hexachlorobenzene (compare *ibid.*, 20, 621), and the resulting polyamines are more easily oxidised. Alcohol extracts from the product a *tribromo-iodobenzene*, needles, m. p. 154—156°, the *aniline* salt of *glyoxylic*

acid, $C_8H_{11}O_4N$, yellowish-white leaflets, m. p. 173°, and also aniline hydrobromide and iodide, whilst the amorphous, dark blue, insoluble residue has the composition of an iodopenta-anilinobenzene.

J. C. W.

Rule of the Conservation of the Type in Benzene Substitutions. ARNOLD F. HOLLEMAN (*Rec. trav. chim.*, 1912, 31, 267—280).— When reviewing the introduction of further substituents into benzene rings which have already been once or twice substituted, only a few doubtful cases were found which were contrary to the rule that the position occupied is independent of the nature of the substituent. It is now shown that the bromination and the nitration of *o*-iodotoluene, the bromination of *o*-chlorotoluene, and the chlorination of *o*-chloronitrobenzene are no longer to be regarded as exceptions to the rule.

Hirtz (A., 1896, i, 531) assigned to the product obtained by brominating *o*-iodotoluene, " by analogy," the constitution

$$Me : I : Br = 1 : 2 : 4,$$
whereas Reverdin (A., 1898, i, 180) showed conclusively that the chief nitration product was $Me : I : NO_2 = 1 : 2 : 5$. The latter compound has now been reduced by means of iron powder, yielding the *iodotoluidine*, $Me : I : NH_2 = 1 : 2 : 5$, as unstable, white leaflets, m. p. 42°, which were diazotised with difficulty in hydrobromic acid solution, and converted into bromoiodotoluene, $Me : I : Br = 1 : 2 : 5$, b. p. 262—265°, $n_{14} = 1·6484$. On the other hand, the direct bromination of *o*-iodotoluene (compare Hirtz, *loc. cit.*) was accomplished in the presence of iron powder, but the product was of a very complicated nature, although the main fraction boiled at 260—265°. Direct comparison of such liquids being impossible, it was sought to obtain crystalline nitro-derivatives of them. The preparation from *o*-iodonitrotoluene, when heated with fuming nitric acid, gave 5-bromo-2 : 6-dinitrotoluene, m. p. 103°. The mixture from the direct bromination, when nitrated in acetic acid, gave a small number of yellowish-green crystals, a *bromoiododinitrotoluene*, m. p. 178—181°, which was the principal product when the highest fraction, b. p. 270—275°, was separately treated. The larger portion, however, remained in solution, and on dilution with water a product was obtained, m. p. 92—93°, which was shown to be a eutectic mixture of the above bromoiododinitrotoluene and the 5-bromo-2 : 6-dinitrotoluene. Assuming that only the 1 : 2 : 5-compound loses iodine on nitration, an estimation of the hydrogen iodide showed that this isomeride formed about 40% of the mixture. The 5-position is therefore entered to a preponderating extent by both the nitro-group and the bromine atom.

In the analogous case of the bromination of *o*-chlorotoluene it is most likely that the product is a mixture of all the possible isomerides, although it is not proved that the prevailing one is the 1 : 2 : 5. This one, however, predominates in the case of the nitration of *o*-chlorotoluene, as Wibaut will soon describe.

Cohen and Bennet (T., 1905, 87, 323) obtained by the chlorination of *o*-chloronitrobenzene the isomerides $Cl_2 : NO_2 = 1 : 4 : 2$ and $1 : 6 : 2$, and a further product which melted at 31° was said by them to be the 1 : 5 : 2 compound. The entry of chlorine into a position meta to

chlorine and para to a nitro-group is contrary to the conservation of type, and it is now shown that the doubtful product is most probably a eutectic mixture of the 1 : 4 : 2 and 1 : 6 : 2 isomerides. J. C. W.

Nitro-derivatives of 2 : 6-Dibromotoluene. JAN J. BLANKSMA (*Chem. Weekblad*, 1912, 9, 968—972. Compare A., 1912, i, 982).—A number of nitro-derivatives of 2 : 6-dibromotoluene have been prepared. The parent substance is obtained by replacing the amino-group in 6-bromo-*o*-toluidine (compare Friedländer, Bruckner, and Deutsch, A., 1912, i, 318) by bromine by the Sandmeyer method, and forms colourless crystals, m. p. 2°, and not as stated by Nevile and Winther (T., 1880, 37, 429). By the action of nitric acid (D 1·45) this substance is converted into 2 : 6-*dibromo-3-nitrotoluene*, pale yellow crystals, m. p. 50°, and not 2 : 6-dibromo-4-nitrotoluene as stated by Nevile and Winther. Its constitution was proved by its formation from 6-bromoacet-*o*-toluidide. On nitration, this substance yields 6-*bromo-3-nitroacet-o-toluidide*, yellow crystals, m. p. 199°, converted by concentrated sulphuric acid into 6-*bromo-3-nitro-o-toluidine*, orange-yellow crystals, m. p. 144°. Exchange of the amino-group of this compound for bromine by the Sandmeyer reaction yields 2 : 6-dibromo-3-nitrotoluene, identical with the product obtained by nitration of 2 : 6-dibromotoluene. Potassium permanganate does not oxidise it to the corresponding benzoic acid derivative. Further nitration converts it into 2 : 6-*dibromo-3 : 5-dinitrotoluene*, colourless crystals, m. p. 161°. Heating with alcoholic ammonia at 100° yields 6-bromo-3 : 5-dinitro-*o*-toluidine, yellow crystals, m. p. 200°; its acetyl derivative forms colourless crystals, m. p. above 300° ; at 150° the product is 3 : 5-*dinitro*-1 : 2 : 6-*tolylenediamine*, light brown crystals, m. p. 298°; the corresponding acetyl derivative forms colourless crystals, decomposing above 300°. At 150° an alcoholic solution of methylamine converts 2 : 6-dibromo-3 : 5-dinitrotoluene into 3 : 5-*dinitro*-1 : 2 : 6-*tolylenedimethyldiamine*, orange-red crystals, m. p. 216°.

Nitration of 2-bromoaceto-*p*-toluidide produces 2-*bromo-5-nitroaceto-p-toluidide*, pale yellow needles, m. p. 120°, converted by concentrated sulphuric acid into 2-*bromo-5-nitro*-p-*toluidine*, orange-red needles, m. p. 165°, which is converted by diazotisation into 2-bromo-5-nitrotoluene, identical with that obtained from 6-bromo-3-nitro-*o*-toluidine.

· Replacement of the amino-group in 2-bromo-5-nitro-*p*-toluidine by bromine by the Sandmeyer reaction yields 2 : 4-*dibromo-5-nitrotoluene*, colourless needles, m. p. 85°. Nitration with nitric and sulphuric acids converts this substance into 2 : 4-dibromo-3 : 5-dinitrotoluene, m. p. 130° (compare Davis, T., 1902, 81, 873), which with alcoholic ammonia at 150° yields 3 : 5-dinitro-1 : 2 : 4-tolylenediamine (compare A., 1904, i, 566). A. J. W.

Preparation of Anthracenemonosulphonic Acids. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 251695).—The preparation of anthracenemonosulphonic acids has previously been

attended with difficulty; it is now found to proceed smoothly if the sulphonation is carried out in the presence of glacial acetic acid.

A solution of anthracene (300 parts) in acetic acid (600 parts) is cooled and slowly treated with chlorosulphonic acid (200 parts), the mixture is rapidly heated to 95°, and maintained at this temperature during five hours; the clear olive-green solution is treated with water (5000 parts), and the insoluble residue subsequently treated with more water (4500 parts) at 40°. The anthracene-α sulphonic acid (in 50% yield) is precipitated from the filtrate with salt, whilst the residue on treatment with a large volume of hot water furnishes anthracene-β-sulphonic acid in over 30% yield.   F. M. G. M.

Tridiphenylylmethyl.   JULIUS SCHMIDLIN (*Ber.*, 1912, 45, 3171—3183).—The tridiphenylylmethyl discovered earlier (Schlenk, Weickel, and Herzenstein, A., 1910, i, 236) is a mixture of two isomerides.

By a modification of the method of the earlier workers good yields of the tridiphenylylcarbinol could be obtained. 4-Bromodiphenyl in ethereal solution was converted by the action of magnesium and successive quantities of iodine into the corresponding organo-magnesium compound which reacted with *p*-bisdiphenylyl ketone, producing a mixture of α- and β-tridiphenylylcarbinol, together with some *p*-tridiphenylylmethane and *p*-bisdiphenyl.   p-*Tridiphenylyl-methane*, obtainable also by the reduction of the mixture of α- and β-tridiphenylylcarbinols, forms colourless crystals, m. p. 241—242° (corr.), and when recrystallised from benzene tenaciously retains benzene of crystallisation even to the m. p.; p-*bisdiphenyl* forms inodorous leaflets, m. p. 318—319° (corr.).

The isomeric carbinols, the relative proportions of which varied considerably in different experiments, could be separated by fractional recrystallisation of the mixture from ether, or by converting into a mixture of   the chlorides and then recrystallising from benzene. α-*Tridiphenylylmethylcarbinol*, the less soluble isomeride, has m. p. 212° (corr.), whilst the β-compound forms leaflets, m. p. 199—200° (corr.); both carbinols, at a concentration of 1 : 60,000, in a mixture of acetic and sulphuric acids give an absorption band from 440 to 510 μμ. The action of acetyl chloride or, better, of hydrogen chloride on the benzene solution converts the carbinols into the corresponding chlorides; α-*tridiphenylylmethyl chloride*, needles, m. p. 200° (corr.); β-*chloride*, m. p. 187—188° (corr.). The two chlorides are convertible by the action of copper powder on the benzene solution into the corresponding tridiphenylylmethyls; α-*tridiphenylylmethyl*, $C(C_6H_4Ph)_3$, is a dark green, crystalline powder, the solution of which is brownish-red, and at a concentration of 1 : 5000 shows an absorption band from 430 μμ to the ultra-violet; the molecular weight in benzene solution was 499, the theoretical being 471.

β-*Tridiphenylylmethyl* forms dark green needles, and gives a deep blue solution, which shows an absorption band (at a concentration 1 : 6000) extending from 600 to 640 μμ; the molecular weight in benzene was 518.   The two tridiphenylylmethyls easily undergo

atmospheric oxidation, producing the α- and β-*tridiphenylylmethyl peroxides*, m. p. 213° (corr.) and 198° respectively.

Experiments were made to ascertain whether so-called triphenyl-methyl can be observed to dissociate into the unimolecular condition. Gomberg and Cone (A., 1904, i, 658) obtained molecular weights in phenol solution indicating a dissociation, but this result was due to chemical interaction between solvent and solute with the formation of *p*-hydroxytetraphenylmethane, m. p. 282°, and triphenylmethane. By determining the alteration of m. p. and b. p. successively with the same benzene solution, it is now shown that the molecular weight is the same at both temperatures, and is only a little lower than that calculated for the bimolecular condition. The alteration in the colour of solutions of triphenylmethyl on warming is, therefore, probably not due to dissociation. D. F. T.

Phenyldiphenylylnaphthylmethyl. JULIUS SCHMIDLIN and ANTONIO GARCIA-BANUS (*Ber.*, 1912, **45**, 3183—3188).—The authors have succeeded in preparing triarylmethane compounds containing an asymmetric carbon atom.

p-*Diphenylyl* α-*naphthyl ketone*, $C_6H_4Ph \cdot CO \cdot C_{10}H_7$, obtained by the action of naphthoyl chloride on diphenyl in carbon disulphide solution under the influence of aluminium chloride, forms plates, m. p. 142° (corr.); when heated with aluminium chloride at 140—145°, it condenses to *phenylbenzanthrone* (annexed formula), golden-yellow plates, m. p. 178—179° (corr.), which gives a fluorescent red solution in concentrated sulphuric acid. The above diphenylyl naphthyl ketone reacts with magnesium phenyl iodide giving *phenyl-p-diphenylyl-α-naphthylcarbinol*, $C_{10}H_7 \cdot CPh(C_6H_4Ph) \cdot OH$, prisms (with ether of crystallisation), m. p. 115—116° (corr.), m. p. when ether-free 164—165° (corr.), together with a small amount of a *substance*, m. p. 197—198°, possibly phenyl-*p*-diphenylyl-α-naphthylmethane. The carbinol, which dissolves in concentrated sulphuric acid to a violet solution, reacts in benzene solution with hydrogen chloride with the formation of *phenyl-p-diphenylyl-α-naphthylmethyl chloride*, a colourless, crystalline powder, m. p. 198—199° (corr.). In an atmosphere of carbon dioxide the chloride is reduced by copper powder to *phenyl-p-diphenylyl-α-naphthylmethyl*, an apparently homogeneous product (compare preceding abstract); this dissolves in benzene to a brown solution, and from the fact that the solution, after most of its colour has been destroyed by atmospheric oxidation, recolorises to some extent, it is suggested that, unlike tridiphenylmethyl, the present substance is not completely dissociated into the active unimolecular condition; the fresh solution (concentration 1 : 5000) shows a broad absorption band from the violet end of the spectrum to 480μμ, and a small band in the yellow; the fresh solution of the corresponding phenyl-*p*-diphenylyl-α-naphthylcarbinol in sulphuric acid gives an absorption spectrum with a band extending from 480μμ half way into the green. Solutions of the above phenyl-*p*-diphenylyl-α-naphthylmethyl are

oxidised by the atmosphere to the *peroxide*, $(C_{29}H_{21})_2O_2$, a colourless, crystalline powder, m. p. 158° (corr., decomp.).

Although triphenylmethyl chloride, by the action of menthol in pyridine solution, can be converted into *triphenylmethyl l-menthyl ether*, m. p. 137—138° (corr.), similar treatment of phenyl-*p*-diphenylyl-*a*-naphthylmethyl chloride produced only the corresponding carbinol. It was also found impossible to prepare the camphorate or camphor-sulphonate. The chloride of the carbinol will not react with nicotine or coniine, and the product obtained by replacing the halogen by the amino-group is not basic in properties. The most promising method for the resolution of the asymmetric carbinol into its enantiomorphous constituents appears to depend on the active *amyl ether* which has been obtained in the crystalline state.   D. F. T.

Reduction of Aromatic Alcohols with Aliphatic Alcohols. JULIUS SCHMIDLIN and ANTONIO GARCIA-BANÙS (*Ber.*, 1912, **45**, 3188—3193 *).—By using sulphuric acid as solvent, the reduction of aromatic secondary and tertiary carbinyl chlorides by aliphatic alcohols, already observed in special cases (for example, Kauffmann and Fritz, A., 1909, i, 99), becomes a fairly general reaction. Triphenylcarbinol and triphenylmethyl chloride, in a mixture of equal volumes of alcohol and sulphuric acid, undergo reduction to triphenylmethane, the action being represented : $CPh_3 \cdot SO_4H + EtOH = CHPh_3 + CH_3 \cdot CHO + H_2SO_4$; the ethyl alcohol can be replaced by methyl alcohol. In a similar manner tridiphenylylmethane and diphenylmethane can be obtained from tridiphenylylmethyl chloride or tridiphenylylcarbinol and benzhydrol respectively. The reaction fails with the naphthalene-carbinols, and also in cases where the sulphuric acid itself can cause dehydration or other effects, as, for example, with *aβ*-diphenylethyl alcohol, which yields stilbene.

The reduction of triphenylmethyl in ethereal solution by hydrogen and platinum black produces only triphenylmethane.

The oxidation of triphenylmethane to the corresponding carbinol can be quantitatively effected by boiling nitric acid, D 1·33 (compare Schwarz, A., 1909, i, 561).

A diagram is given for an apparatus designed for the preparation of fairly large quantities of triphenylmethyl and analogous compounds.

Endeavours to prepare a "mixed" ethane derivative by the inter-action of magnesium triphenylmethyl chloride and tridiphenylylmethyl chloride produced only a mixture of triphenylmethyl and tridiphenylyl-methyl ; also no crystalline product could be obtained from the same Grignard reagent and phenylfluorenyl chloride.   D. F. T.

Valency of Carbon, Arsenic, and Silicon. WILHELM SCHLENK (*Annalen*, 1912, **394**, 178—223).—[With LEOPOLD MAIR.]—The deepening of the colour of a solution of triphenylmethyl by warming has been attributed to the shifting of the equilibrium of the system $CPh_3 \cdot CPh_3 \rightleftharpoons 2CPh_3$ from left to right. Gomberg has shown by the cryoscopic method that triphenylmethyl in cold benzene exists almost entirely as hexaphenylethane. The authors now show by the ebullio-

---

* and *Anal. Fis. Quim.*, 1212, **10**, 449—454.

scopic method that at its b. p. the solution contains about 25% of triphenylmethyl.

Since triphenylmethyl peroxide and diphenylenephenylmethyl oxide (diphenylfluorene ether; Kliegl, A., 1905, i, 187) are comparatively stable substances, the authors hoped to prepare triphenylmethyl oxide, $(CPh_3)_2O$, from chlorotriphenylmethane by the action of silver oxide or of the sodium derivative of triphenylcarbinol. The products in both cases, however, are triphenylcarbinol and resinous substances.

[With C. BORNHARDT.]—The same products are also obtained by the oxidation of triphenylmethyl in glacial acetic acid or acetone by chromic acid or potassium permanganate.

After keeping triphenylmethyl and sulphur in carbon disulphide in darkness for six to eight weeks, the hydrocarbon is completely converted into an inseparable mixture of triphenylmethyl polysulphides.

A benzene solution of triphenylmethyl and an alcoholic ethereal solution of diazomethane react to form *hexaphenylpropane*,

$$CPh_3 \cdot CH_2 \cdot CPh_3,$$
a more complete description of which is promised.

[With JULIUS RENNING.]—By heating a benzene solution of phenyl-xanthenol chloride, prepared by Gomberg's method (A., 1910, i, 56), with copper-bronze on the water-bath, *phenylxanthyl*,

$$C_6H_4 \underset{O}{\overset{CPh}{<}} C_6H_4,$$
is obtained. It forms brown crystals which disintegrates to a yellow powder at 60° in carbon dioxide, and is shown to be present in the unimolecular form to the extent of about 82% in boiling 1—2% benzene solution by the ebullioscopic method. *Phenylthioxanthyl*, $C_6H_4 \underset{S}{\overset{CPh}{<}} C_6H_4$, prepared in a similar manner from phenylthio-xanthenol chloride (Gomberg, A., 1910, i, 869), is a brownish-red, crystalline powder, and is present in the unimolecular form to the extent of about 14% in cold benzene. *Phenylanthronyl*,

$$C_6H_4 \underset{CO}{\overset{CPh}{<}} C_6H_4,$$
is a yellow, crystalline powder; a 1—2% benzene solution contains in the cold about 33% of the unimolecular form. *Diphenyl-a-naphthyl-methyl*, $C_{10}H_7 \cdot CPh_2$, obtained by boiling *chlorodiphenyl-a-naphthyl-methane*, m. p. 163°, with copper bronze in petroleum, b. p. 60—75°, in an atmosphere of carbon dioxide, is a greyish-black powder; a 2—3% solution in cold benzene contains about 59% of the uni-molecular form. *Phenyl-p-diphenylyl-a-naphthylmethyl*,

$$C_6H_4Ph \cdot CPh \cdot C_{10}H_7,$$
prepared in a similar manner from *chlorophenyldiphenylyl-a-naphthyl-methane*, m. p. 194·5°, is an olive-brown powder; a 1—3% solution in cold benzene contains the unimolecular form almost entirely.

[With LEOPOLD MAIR.]—p-*Anisyldiphenylenecarbinyl chloride*,

$$\overset{C_6H_4}{\underset{C_6H_4}{>}} CCl \cdot C_6H_4 \cdot OMe,$$
m. p. 149—151°, prepared by treating fluorenone with magnesium p-anisyl iodide in ether, decomposing the product in the usual manner,

and saturating a cold ethereal solution of the resulting carbinol with hydrogen chloride, reacts with copper-bronze in boiling benzene in an atmosphere of carbon dioxide to form *di-p-anisylbisdiphenylene-ethane*, $C_{40}H_{30}O_2$, m. p. 170—190° (decomp.) in open tube, 227—230° in carbon dioxide in a closed tube.   It is a white, crystalline powder, stable in air, and forms solutions which become brown by warming and almost colourless again by cooling ; its solution in benzene absorbs oxygen and yields the *peroxide*, $C_{40}H_{30}O_4$, m. p. 192°, colourless prisms.

[With ANNA HERZENSTEIN.]—The formation of triarylmethyls by the action of metals on solutions of triarylcarbinyl chlorides bears some resemblance to the elimination by one metal of another from a solution of its salts.   In fact, when equal molecular quantities of triphenylmethyl and of phenyldidiphenylylcarbinyl chloride are brought together in benzene, the colour of the solution quickly darkens in consequence of the liberation of red phenyldidiphenylylmethyl by the yellow triphenylmethyl.   Still more striking is the reaction which occurs when a benzene solution of phenylnaphthyldiphenylylcarbinyl chloride is added slowly to a solution of triphenylmethyl ; each drop produces, with the rapidity of an ionic reaction, the deep reddish-brown coloration of phenyldiphenylylnaphthylmethyl.

[With GEORG RACKY and C. BORNHARDT.]—Attempts to prepare tervalent carbon derivatives containing radicles other than aryl groups show that such substances are not formed or usually exist in the dimolecular state ; thus Wieland's benzpinacone diphenyl ether exists as such ; only at high temperatures does it change to phenoxy-diphenylmethyl (A., 1911, i, 851).   The action of metals on chlorides of the type CAr_2RCl should yield hydrocarbons CAr_2R.   When R is methyl or other alkyl group containing CH, however, the chloride cannot be isolated, since it spontaneously loses hydrogen chloride with the formation of diarylolefines.   *Diphenyl-tert.-butylcarbinyl chloride*, $CPh_2Cl\cdot CMe_3$, m. p. 103—106°, large, colourless crystals, can be obtained by the interaction of magnesium phenyl bromide and ethyl trimethylacetate in ether, the product, isolated in the usual manner being saturated in ether with hydrogen chloride and finally boiled with acetyl chloride.   By boiling in xylene with sodium, the chloride yields *diphenyldi-tert.-butylethane*, $CMe_3\cdot CPh_2\cdot CPh_2\cdot CMe_3$, which has no tendency to dissociate into the tervalent carbon derivative. *βββ-Trichloro-α-bromo-αα-diphenylethane*, $CPh_2Br\cdot CCl_3$, m. p. 87·5°, colourless crystals, obtained by treating the trichlorodiphenylethane with an excess of bromine, loses chlorine and bromine by treatment with metals.

By treatment with liquid nitrogen peroxide, tetraphenylethylene in chloroform yields *pp'-dinitrotetraphenylethylene*,

$$NO_2\cdot C_6H_4\cdot CPh\colon CPh\cdot C_6H_4\cdot NO_2,$$
m. p. 150—190°, citron-yellow crystals.   In boiling nitrobenzene the two substances do not react.   Bis-diphenylene-ethylene in chloroform and nitrogen peroxide yield *dinitrobisdiphenylene-ethane*,

$$\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix}{>}C(NO_2)\cdot C(NO_2){<}\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix},$$
colourless crystals, which is stable, but decomposes by melting (178°) and yields fluorenone and nitric oxide, whilst by heating with phenol it yields nitrophenol and bisdiphenylene-ethylene.

Tetradiphenylylethylene, which is obtained readily by boiling *diphenylyl ketochloride*, $CCl_2(C_6H_4Ph)_2$. m. p. 136°, in xylene with copper bronze, reacts with nitrogen peroxide in chloroform to form a blue substance, which rapidly decomposes, yielding diphenylyl ketone.

[With GEORG RACKY.]—The vapour density of arsenic disulphide at about 900° corresponds with the formula As_2S_3. The authors' experiments on the molecular weight of arsenic di-iodide in boiling benzene lead conclusively to the formula As_2I_4 (compare Hewitt and Winmill, T., 1907, 91, 962). The molecular weight of tetraphenyl-cacodyl in boiling benzene corresponds with the formula As_2Ph_4. Consequently there is no evidence of the existence of bivalent arsenic compounds.

[With JULIUS RENNING.]—Silicon tetrachloride in ether is treated with magnesium phenyl bromide (2 mols.) and subsequently with magnesium methyl iodide. After treatment with water, the mixture is fractionally distilled, whereby *diphenylsilicoethylene*, $SiPh_2:CH_2$, is obtained. It is a colourless, odourless liquid, b. p. 266—268°/720 mm., which does not react with bromine or decolorise alkaline potassium permanganate.   C. S.

Spirans. VI. Some Properties of the Spiran Carbon Atom. DAN RADULESCU (*Chem. Zentr.*, 1912, ii, 1363—1366; from *Bul. Soc. Ştiinţe Bucareşti*, 21, 32—58. Compare A., 1912, i, 179).— The influence of the spiran carbon atom on the stability of, and on the conditions for the formation of, the two rings which it connects, and also on the reactivity of single members of the rings, is discussed. No steric hindrance exists which prevents the closing of spiran rings; in fact, spirans with five or six atoms in the ring are more stable than analogous compounds with open chains, so that the tendency is to form closed rings. The behaviour of the spiran carbon atom in strained ring systems has been studied in the case of *cyclo*propane-*cyclo*pentane-2 : 5-dione-1 : 1-spiran-3 : 4-dicarboxylic acid and its derivatives. The stability of the trimethylene ring is scarcely lessened by the spiran carbon atom.

The chromophoric properties of the rings are also affected by the quaternary system of the spiran carbon atom ; the two spiran bonds in one ring act like a double link on the other ring. The group II is a stronger chromophore than the group I.

(I.)   (II.)   (III.)
Anhydro-derivatives of the type III give yellow solutions which

with strong alkalis become blue. Carminic acid develops the same colour with very concentrated, strong bases, and has an absorption spectrum which is almost identical with that of compounds of this type.

Fecht's indan-1 : 3-dione-indan-2 : 2-spiran (xylylenediketohydrindene) (A., 1907, i, 906) is found to be impure. Repeated solution in benzene and precipitation with light petroleum separates from it *anhydrobis-indan*-1 : 3-*dioneindan*-2 : 2-*spiran*, $C_{34}H_{22}O_3$, (V), in pale yellow flakes, m. p. 256—257°, which give with phenylhydrazine the brownish-red hydrazone of Fecht's spiran. A very dilute alcoholic solution develops an intense indigo colour with a drop of concentrated potassium hydroxide, whereas the pure indan-1 : 3-dione-indan-2 : 2-spiran (IV) gives no coloration. The latter forms golden-yellow, thick prisms, m. p. 149°, and gives a violet colour to concentrated sulphuric acid. The ethereal mother liquors from this compound still contain *indan*-1 : 3-*dione*-1-*ethoxyindan*-2 : 2-*spiran*, $C_{19}H_{16}O_3$, (VI), which forms yellow prisms, m. p. 199—200°, and imparts a red colour to sulphuric acid, but is not affected by alkalis.

$$(IV.) \quad C_6H_4 \underset{CO}{\overset{CO}{\diamondsuit}} C \underset{CH_2}{\overset{CH_2}{\diamondsuit}} C_6H_4$$

$$(VI.) \quad C_6H_4 \underset{CO}{\overset{CO}{\diamondsuit}} C \underset{CH \cdot OEt}{\overset{CH_2}{\diamondsuit}} C_6H_4$$

$$(V.) \quad C_6H_4 \underset{\overset{C}{C}}{\overset{CO}{\diamondsuit}} C \underset{CH_2}{\overset{CH_2}{\diamondsuit}} C_6H_4 \quad ; \quad C_6H_4 \underset{CH_2}{\overset{C}{\diamondsuit}} C \underset{CO}{\overset{CH_2}{\diamondsuit}} C_6H_4$$
1-*Imino*-3-*indanoneindan*-2 : 2-*spiran*, $C_{17}H_{13}ON$, (VII), obtained by heating the spiran (IV) with alcoholic ammonia, separates in brick-red flakes.

$$(VII.) \quad C_6H_4 \underset{C:NH}{\overset{CO}{\diamondsuit}} C \underset{CH_2}{\overset{CH_2}{\diamondsuit}} C_6H_4$$

$$(VIII.) \quad \overset{CH_2}{\underset{CH_2}{>}} C \overset{CO}{\underset{CO}{<}} \overset{CH \cdot CO_2H}{\underset{CH \cdot CO_2H}{}}$$
*cyclo*Propane*cyclopentanedione*-1 : 1-*spiran*-3 : 4-*dicarboxylic acid*, (VIII), from ethyl *cyclo*propane-1 : 1-dicarboxylate, ethyl succinate, and sodamide, is converted at 180—200° or by heating with acetic anhydride into the *anhydride*, $C_9H_6O_5$, small, white needles.

Bisdihydroxyquinoline - 3 : 3 - *spiran* (*bisdihydrocarbostyrylspiran*), $C_{17}H_{14}O_2N_2$, (IX), from the reduction of ethyl di-*o*-nitrobenzyl-malonate, sublimes above 360° in colourless, shining flakes, which dissolve when hydrogen bromide is passed into a suspension of the substance in acetic acid.

$$(IX.) \quad C_6H_4 \underset{N \quad C}{\overset{CH_2}{<}} C \overset{CH}{\underset{C \quad N}{>}} C_6H_4$$
$$\overset{}{\underset{OH \quad OH}{}}$$

$$(X.) \quad C_6H_4 - H_2C - C - CH_2 - C_6H \quad$$
$$\overset{}{\underset{NH_2 \quad EtO_2C \quad CO_2Et \quad NH_2}{}}$$
When the mother liquors from the reduction are treated with

ammonia, the reddish primary product of the reaction, the *amino*-ester (X), separates out. It readily loses alcohol, forming the spiran.

Ethyl di-p-nitrobenzylmalonate, $C(CH_2 \cdot C_6H_4 \cdot NO_2)_2(CO_2Et)_2$, white needles, m. p. 171°, is the chief product when ethyl dibenzylmalonate is nitrated by fuming nitric acid in glacial acetic acid.

J. C. W.

Stereochemistry of Quinquevalent Nitrogen. I. Formation and Decomposition of the Quaternary Ammonium Bases and Salts. SHIGERU KOMATSU (*Mem. Coll. Sci. and Eng., Kyoto Imp. Univ.*, 1912, **3**, 371—426).—The author has prepared a long series of quaternary ammonium compounds, and finds m. p.'s for the iodides which generally show considerable divergence from those previously stated by Jones and by Wedekind. In the thermal decomposition of the hydroxides it is observed that in the series $HO \cdot NPh(CH_2Ph)XY$ the benzyl group is always the one to be eliminated; with the series $HO \cdot NPh(C_3H_5)XY$, if X and Y are smaller groups than the allyl, the last undergoes scission, but if one is larger and the other smaller than the allyl, the smaller of X and Y becomes removed. Apart from these two classes it is found that, as a general rule, the smallest group is always left attached to the nitrogen atom.

The following tertiary bases and derivatives were obtained. Dimethylaniline gives a *picrate*, needles, m. p. 154—155°, and combines with mercuric chloride giving a yellow *compound*, crystallising in needles, also a basic *compound*, $O(Hg \cdot NMe_2PhCl)_2$, pearly scales, and a *double* salt, $NMe_2Ph, HCl, HgCl_2$, colourless needles. Methylethylaniline gives a *picrate*, prisms, m. p. 121—122°; *ferrocyanide*, colourless crystals, and combines with mercuric chloride producing a colourless, scaly basic *compound*, $O(Hg \cdot N \cdot PhMeEtCl)_2$, and a *double* salt, colourless needles. Methylallylaniline forms a picrate, m. p. 81—82°, and *ferrocyanide*, colourless crystals. Methylpropylaniline gives a *picrate*, m. p. 103—104°; *ferrocyanide*, colourless. Methyl-*n*-butylaniline, b. p. 225—230°, forms a *picrate*, rhombic needles, m. p. 141—142°; *ferrocyanide*, light green, crystalline powder. Methyl*iso*butylaniline yields a *picrate*, plates, m. p. 99—100°, and *ferrocyanide*, colourless. Methyl*iso*amylaniline forms a *picrate*, m. p. 93—94°, and *ferrocyanide*, light green. Benzylmethylaniline gives a *picrate*, rhombic prisms, m. p. 101—101·5°; *ferrocyanide*, colourless; colourless *double* salt, $(NMePh \cdot CH_2Ph, HCl)_2CdCl_2$, with cadmium chloride, and with mercuric chloride a mixture of a yellow *substance* (which on exposure to air is slowly converted into a blue *substance*, m. p. about 160°), a basic *substance*, crystallising in white needles (composition analogous to that of the basic substances above), and a *double* salt, $(NMePh \cdot CH_2Ph, HCl)_2, HgCl_2$, colourless needles. Ethylallylaniline gives a *picrate*, prisms, m. p. 98—99°, and *ferrocyanide*, colourless. Ethyl-*n*-propylaniline forms a *picrate*, crystalline powder, m. p. 94—95°, and *ferrocyanide*, colourless. Ethyl-*n*-butylaniline gives a *picrate*, rhombic prisms, m. p. 89—90°, and *ferrocyanide*, colourless. Ethyl*iso*butylaniline yields a *picrate*, crystals, m. p. 91—92°, and *ferrocyanide*, light green, crystalline powder. Ethyl*iso*amylaniline forms a *picrate*, rhombic prisms, m. p. 103—104°, and

ferrocyanide, light green, crystalline powder.   Benzylethylaniline gives a picrate, rhombic prisms, m. p. 110—111°; *ferrocyanide*, light green, crystalline powder, a *double* salt (colourless needles) with cadmium chloride, and with mercuric chloride a colourless, crystalline basic *substance* and a *double* salt (needles), $(NEtPh \cdot CH_2Ph, HCl)_2, HgCl_2$. Diethylaniline, *picrate*, m. p. 135—136°.

The m. p. of each of the above picrates, as also of most of the iodides below, was also determined by the Kuhara-Chikashigé method (A., 1900, ii, 260), the results differing occasionally by several degrees from those obtained by the ordinary method.

The following quaternary compounds were examined : Phenylbenzyldimethylammonium iodide, m. p. 141—142° (compare Jones, T., 1903, 83, 1409), obtained from dimethylaniline and benzyl iodide ; *platinichloride*, needles, m. p. 164—165° ; the *hydroxide* when heated decomposes, giving dimethylaniline. Phenylbenzylmethylethylammonium iodide, m. p. 135—136° (compare Jones, T., 1904, 85, 224 ; Fröhlich, A., 1910, i, 375), from methylethylaniline and benzyl iodide ; *platinichloride*, needles, m. p. 160·5—161° ; the *hydroxide* decomposes, giving methylethylaniline. Phenylbenzylmethylallylammonium iodide, rhombic prisms, m. p. 128—129° (compare Jones, T., 1905, 87, 1721 ; Wedekind, A., 1899, i, 351), obtained from methylallylaniline and benzyl iodide, or from benzylmethylaniline and allyl iodide ; *platinichloride*, needles, m. p. 133—134° ; the *hydroxide* when decomposed yields methylallylaniline.   Phenylbenzylethyl-*n*-propylammonium   iodide, prisms, m. p. 143°, from methyl-*n*-propylaniline and benzyl iodide ; *platinichloride*, needles, m. p. 159—160° ; the *hydroxide* on decomposition gives methyl-*n*-propylaniline. Phenylbenzylmethyl*iso*butylammonium iodide, prisms, m. p. 124—125°, obtained from methyl*iso*butylaniline and benzyl iodide ; *platinichloride*, needles, m. p. 147—148° ; the *hydroxide* on decomposition gives methyl*iso*butylaniline. *Phenylbenzylmethyl-n-butylammonium iodide*, needles, m. p. 132—133°, obtained from methyl-*n*-butylaniline and benzyl iodide ; *platinichloride*, needles, m. p. 139—140° ; the *hydroxide* on decomposition gives methyl-*n*-butylaniline. Phenylbenzylmethyl*iso*amylammonium iodide, from methyl*iso*amylaniline and benzyl iodide, needles, m. p. 137—138° (compare Thomas and Jones, T., 1906, 89, 280) ; *platinichloride*, needles, m. p. 149—150° ; the *hydroxide* on decomposition gives methyl*iso*amylaniline. Phenyldibenzylmethylammonium iodide, m. p. 105—106° from benzylmethylaniline and benzyl iodide (compare Jones, T., 1903, 83, 1410) ; *platinichloride*, needles, m. p. 131—132° ; the *hydroxide* on decomposition yields benzylmethylaniline. *Phenylbenzylethyl-n-propylammonium iodide* from ethyl-*n*-propylaniline and benzyl iodide, prisms, m. p. 105—106° ; *platinichloride*, needles, m. p. 146—147° ; the *hydroxide* on decomposition yields ethyl-*n*-propylaniline.

Phenylbenzylethylallylammonium iodide, obtained from ethylallylaniline and benzyl iodide, prisms, m. p. 106·5° ; *platinichloride*, needles, m. p. 138—139°.   Phenyldimethylallylammonium iodide, from dimethylaniline and allyl iodide, prisms, m. p. 84—85° ; the *hydroxide* on decomposition gives dimethylaniline. *Phenyldiethylallylammonium*

iodide from ethylallylaniline and ethyl iodide, or from diethylaniline and allyl iodide; *platinichloride*, needles, m. p. 158—159°; the *hydroxide* on decomposition gives diethylaniline. Phenylmethyl-*n*-propylallylammonium iodide, prisms, m. p. 119—120°, from methyl-*n* propylaniline and allyl iodide, or as a gummy mass from methylallylaniline and *n*-propyl iodide; *platinichloride*, needles, m. p. 157—158°; the *hydroxide* on decomposition gives *n*-propylallylaniline. Phenylmethyl*iso*butylallylammonium iodide from methyl*iso*butylaniline and allyl iodide, needles, m. p. 124°; *platinichloride*, needles, m. p. 156—157°; the *hydroxide* on decomposition yields *iso*butylallylaniline. Phenylmethyl*iso*amylallylammonium iodide, prisms, m. p. 126—127°, from methyl*iso*amylaniline and allyl iodide; *platinichloride*, needles, m. p. 154—155°; the hydroxide on decomposition gives *iso*amylallylaniline.

Phenylmethylethyl-n-butylammonium iodide, prisms, m. p. 72—73°, obtained from methylethylaniline and *n*-butyl iodide, also from ethyl-*n*-butylaniline and methyl iodide; *platinichloride*, needles, m. p. 195—196°, was obtained also from the gummy reaction product of methyl-*n*-butylaniline and ethyl iodide; the *hydroxide* on decomposition gives methyl-*n*-butylaniline. *Phenylmethylethylisoamylammonium iodide*, needles, m. p. 154°, was obtained from ethyl*iso*amylaniline and methyl iodide, also from methylethylaniline and *iso*amyl iodide, and from methyl*iso*amylaniline and ethyl iodide; *platinichloride*, m. p. 191—192°; the *hydroxide* on decomposition gives methyl*iso*amylaniline.

Phenylmethyl-n-propylisobutylammonium iodide, a viscous mass, from methyl*iso*butylaniline and *n*-propyl iodide, and also from methyl-*n*-propylaniline and *iso*butyl iodide; *platinichloride*, needles, m. p. 200—201°; the *hydroxide* on decomposition yields methyl-*n*-propylaniline.

Phenylmethyl-n-propylisoamylammonium iodide, obtained as a gummy mass from methyl*iso*amylaniline and *n*-propyl iodide and also from methylpropylaniline and *iso*amyl iodide; platinichloride, needles, m. p. 183—183·5°; the hydroxide on decomposition gives methyl-*n*-propylaniline. *Phenylmethyl-n-butylisoamylammonium iodide*, obtained as a gummy mass from methyl*iso*amylaniline and *n*-butyl iodide, and also from methyl-*n*-butylaniline and *iso*amyl iodide; *platinichloride*, needles, m. p. 191—192°; the hydroxide on decomposition gives methyl*iso*amylaniline.   D. F. T.

Esters Derived from Cyclanols and Acids of the Formic Acid Series. JEAN B. SENDERENS and JEAN ABOULENC (*Compt. rend.*, 1912, 155, 1012—1014).—By a method previously described (A., 1912, i, 694) a series of esters has been prepared from *cyclo*hexanol and the three methyl *cyclo*hexanols and formic, acetic, propionic, butyric, *iso*butyric, and *iso*valeric acids. They are all colourless liquids with a pleasant odour, and are not affected by light, save the o-methyl*cyclo*hexyl esters, which turn slightly yellow on prolonged exposure. The following physical constants were determined. The b. p.'s are all at 750—753 mm.:

	cycloHexyl.		Methylcyclohexyl.							
			Ortho.			Meta.			Para.		
	b. p.	D_4^0	b. p.	D_4^0	n_D^{18}	b. p.	D_4^0	n_D^{18}	b. p.	D_4^0	n_D^{15}
Formate	162·5°	1·0057	173·0°	0 9813	—	176 5°	0·9775	—	177·5°	0·9761	—
Acetate	174·0	0·9854	184 5	0·9636	—	187·5	0·9592	—	188 5	0·9578	—
Propionate ...	193·0	0·9718	203·0	0·9548	1·444	206·0	0·9509	1·442	207·0	0·9492	1·4425
Butyrate	212·0	0·9572	221·5	0·9443	1·445	224·5	0 9403	1·4435	225·5	0·9386	1·443
isoButyrate...	204 0	0·9489	212·5	0·9364	1·441	215·0	0·9318	1·440	216·0	0·9304	1·4395
isoValerate...	223·0	0·9425	231·5	0·9316	1·444	234·0	0·9275	1·4425	235·0	0·9262	1·4425

In passing up the acid series there is an increase of 18·5—19° in the b. p. from one homologue to the next higher, except in the case of the formates, whilst the densities decrease, but in an irregular manner.

W. G.

Esterification of Cyclanols by Aromatic Acids. JEAN B. SENDERENS and JEAN ABOULENC (*Compt. rend.*, 1912, 155, 1254—1256). —Applying the method used for fatty acids (A., 1912, i, 694) to aromatic acids having the carboxyl group attached to the benzene nucleus, in no case was an ester obtained, but the cyclohexanol was always converted into cyclohexene. If, however, the carboxyl group is in the side-chain, condensation readily occurred, and the following esters were prepared:

cycloHexyl phenylacetate, b. p. 180·5°, D_0^0 1·0535, n_D^{13} 1·518.

cycloHexyl phenylpropionate, b. p. 193·5°, D_0^0 1·0432, n_D^{13} 1·515.

o-Methylcyclohexyl phenylacetate, b. p. 186°, D_0^0 1·0374, n_D^{13} 1·512; the meta-isomeride, b. p. 188°, D_0^0 1·0323, n_D^{13} 1·510; and the para-isomeride, b. p. 188·5°, D_4^0 1·0316, n_D^{13} 1·509.

o-Methylcyclohexyl phenylpropionate, b. p. 198·5°, D_0^0 1·0286, n_D^{13} 1·510; the meta-isomeride, b. p. 200°, D_0^0 1·0235, n_n^{13} 1·508; and the para-isomeride, b. p. 200·5°, D_4^0 1·0235, n_D^{13} 1·507.

Menthyl phenylacetate, an oily liquid, b. p. 205·5°/25 mm., D_4^{17} 0·9887.

Menthyl phenylpropionate, needles, m. p. 28·5°, b. p. 216°/25 mm.

W. G.

Action of Potassium Hydroxide on cycloHexanol; Synthesis of cycloHexylcyclohexanol and of Dicyclohexylcyclohexanol. MARCEL GUERBET (*Compt. rend.*, 1912, 155, 1156—1159. Compare A., 1912, i, 67, 154).—cycloHexanol, like other secondary alcohols, undergoes condensation when heated at 230° with potassium hydroxide, some oxidation also occurring with the formation of potassium salts of acids. The following products were obtained by this method:

2-cycloHexyl-3-cyclohexanol, $\begin{array}{c}CH_2 \cdot CH_2 \cdot CH \cdot C_6H_{11} \\ CH_2 \cdot CH_2 \cdot CH \cdot OH\end{array}$, a colourless, oily liquid, b. p. 178—180°/55 mm., D_0^0 0 9950, which yields an acetate, a colourless liquid with a pleasant odour, b. p. 188—190°/52 mm. On oxidation with chromic acid the alcohol is converted into 2-cyclo-

hexyl-3-cyclo*hexanone*, $C_6H_{11}\cdot C_6H_9O$, a colourless liquid, b. p. 176—178°/ 54 mm., yielding an *oxime*, m. p. 102°, and a *semicarbazone*, m. p. 149—150°.

A product of further condensation is 2-*dicyclohexyl*-3-cyclo*hexanol*,

$\begin{array}{l}CH_2\cdot CH_2\cdot CH\cdot C_6H_{10}\cdot C_6H_{11}\\ CH_2\cdot CH_2\cdot CH\cdot OH\end{array}$, prismatic crystals, m. p. 124°.

The acids obtained due to a secondary reaction are hexoic acid, b. p. 204—207°, and cyclo*hexylcyclohexanoic acid*, $C_6H_{11}\cdot C_6H_{11}O_2$ (?), a colourless, oily liquid, b. p. 218—220°/69 mm., D_4^0 1·010, yielding a *barium* salt, crystallising from alcohol. W. G.

Catalytic Action. V. Comparison of the Action of Various Catalysts III. Acetylation of *o* Nitrophenol, Carbazole, and Diphenylamine, and Some Observations on *o*-Nitroaniline and Tribromophenol as well as their Acyl Derivatives. JACOB BÖESEKEN (*Rec. trav. chim.*, 1912, 31, 350—366. Compare A., 1911, i, 22).—Further acetylations have been studied in order to find a simple reaction on which quantitative researches on the influence of catalysts may be based. As a rule, the acetylation of primary amines is too complicated, for both mono- and di-acyl compounds are often produced; thus when *o*-nitroaniline is warmed for a quarter of an hour with acetic anhydride and a trace of sulphuric acid or aluminium chloride, the resulting diaceto-*o*-nitranilide contains a little of the mono-derivative.

The case of *s.*-tribromophenol has already been studied by Smith and Orton (T., 1909, 95, 1063), but their method is criticised, for the acetic acid employed may have influenced the catalysts and their estimation of the final products does not seem to have been trustworthy, since the acetate is somewhat saponified on boiling with water. Titration of the alkali required to saponify the acetate is also found unsatisfactory. The solidification points of mixtures of tribromophenol (m. p. 92·5°) with the acetate (m. p. 82°) have therefore been plotted, but the curve is irregular, and indicates the formation of molecular compounds with m. p. about 65°.

In the case of *o*-nitrophenol, however, a simple solidification curve has been obtained, and found to provide the best means of estimating a mixture of the two compounds. The product of the reaction is washed with ice water, extracted with benzene, and the extract is dried and allowed to evaporate at 50°. By this means it is found that *o*-nitrophenol is acetylated by acetic anhydride at 98° to the extent of 92% in about four and a-half hours. Hydrogen chloride has only a feeble influence, for in one and a-half hours and with 50 molecules of the gas per 100, the process is only two-thirds complete, whereas 3 molecules per 100 of aluminium chloride complete the reaction in one and a-half hours, and 3 molecules per 100 of anhydrous ferric chloride do so in ten minutes.

Diphenylamine is so completely acetylated without catalytic agency on heating with acetic anhydride on the steam-bath that the present studies were carried out at 45°, again with the aid of a solidification curve. Fuming sulphuric acid, ferric chloride, aluminium chloride, and acetyl chloride have nearly equal effects, and the conclusion is drawn

that the catalysts have formed compounds with one of the systems already present, and that it is their influence that is being studied. The formation of sulphacetic acid and probably mono- and di-acetyl-sulphuric acids from acetic anhydride and sulphuric acid (Franchimont, A., 1881, 716) is of importance in this connexion, as well as the fact that aluminium chloride and acetic anhydride produce acetyl chloride (see this vol., i, 6).

Since carbazole is unaffected by alcoholic potash, it was found possible to analyse the mixture by titrating the alkali required for the saponification of the acyl derivative. Without a catalyst, scarcely any acetylation has taken place after five hours at 98°, but with a trace of sulphuric acid or with quite minute amounts of ferric chloride, the process is complete in half an hour.   J. C W.

Nitro-derivatives of Diphenylene Oxide and of Phenyl Ether. ALPHONSE MAILHE (*Bull. Soc. chim.*, 1912, [iv], 11, 1011—1014).—An error in the calculation of nitrogen has led to the description of nitro-derivatives of phenyl ether containing more than four nitro-groups (Mailhe and Murat, A., 1912, i, 346), of penta- and hexa-nitrodiphenylene oxides, and of the disulphonic acid derivative of the latter (Mailhe, A., 1912, i, 553). These substances do not exist.   H. W.

m-**Dithiolbenzene (Dithioresorcinol).** THEODOR ZINCKE and OTTO KRUGER (*Ber.*, 1912, 45, 3468—3479).—The *m*-Dithiolbenzene was prepared in the ordinary way from benzene-1 : 3-disulphonyl chloride by reduction with zinc and hydrochloric acid. In order to obtain good yields the zinc sulphinate must first be formed by the action of the zinc on the chloride in alcoholic solution, and afterwards reduced to the mercaptan by the addition of hydrochloric acid and further action of the zinc. If this method of procedure is not adopted, the free sulphinic acid and the mercaptan react with the formation of tetra- or poly-sulphides.

The following derivatives of *m*-dithiolbenzene have been prepared. *Di*-1 : 3-*phenylene disulphide*, $S_2(C_6H_4)_2S_2$, prepared by the action of perhydrol in alkaline alcoholic solution, forms a yellowish-white, amorphous powder. 4 : 6-*Dichloro*-1 : 3-*dichlorothiolbenzene*,
$$C_6H_2Cl_2(SCl)_2,$$
is obtained by chlorination in chloroform solution. It may also be prepared from the benzyl ester. It forms yellow, glistening needles, m. p. 103°, and shows the usual reactions of the arylsulphur chlorides. When warmed with acetone, it gives slender, colourless needles of 4 : 6-*dichloro*-1 : 3-*diacetonylthiolbenzene*, $C_6H_2Cl_2(S\cdot CH_2Ac)_2$, m. p. 97°.

On methylation with methyl sulphate, *m*-dithiolbenzene gives 1 : 3 *dimethylthiolbenzene*, $C_6H_4(SMe)_2$, a strongly refracting liquid with characteristic odour, b. p. 149°/17 mm., which on treatment with 1 : 4-nitric acid in glacial acetic acid solution yields 4-*nitro*-1 : 3-*dimethyl-thiolbenzene*, $NO_2\cdot C_6H_3(SMe)_2$, yellow, glistening needles, m. p. 114°. The disulphoxide is formed at the same time. 1 : 3-*Diethylthiol-benzene*, $C_6H_4(SEt)_2$, is similar to the dimethyl ether, and has b. p.

164°/18—19 mm. 1 : 3-*Dibenzylthiolbenzene*, $C_6H_4(S \cdot CH_2Ph)_2$, crystallises in leaflets, m. p. 50°.

4 : 6-*Dichloro*-1 : 3-*dimethylthiolbenzene*, $C_6H_2Cl_2(SCH_3)_2$, prepared from the dimethyl ether by chlorination in glacial acetic acid solution, crystallises in long, glistening needles, m. p. 123°. When chlorination takes place in chloroform solution, 1 : 3-*ditrichloromethylthiolbenzene*, $C_6H_4(S \cdot CCl_3)_2$, is obtained as crystals, having the m. p. 106°. Under the action of aniline, fission occurs with the formation of dithiolbenzene and triphenylguanidine.

When the dimethyl ether is treated with bromine in chloroform solution, stout, dark, orange needles of 4 : 6-*dibromo*-1 : 3-*dimethylthiolbenzene dibromide*, $C_6H_2Br_2(SMe) \cdot SBr_2Me$, are obtained. When shaken with sodium hydrogen sulphite solution in the presence of chloroform, 4 : 6-*dibromo*-1 : 3-*dimethylthiolbenzene* itself, $C_6H_2Br_2(SMe)_2$, is obtained as colourless, glistening needles, m. p. 142°. The same compound may be obtained from the disulphoxide by treatment with hydrogen bromide. 4 : 6-*Dibromo*-1 : 3-*diethylthiolbenzene tetrabromide*,

$$C_6H_2Br_2(SBr_2 \cdot Et)_2,$$
results from the bromination of the diethyl ether in chloroform solution; it forms dark red, in reflected light steel-blue, needles, which readily lose bromine under the action of sodium hydrogen sulphite, giving 4 : 6-*dibromo*-1 : 3-*diethylthiolbenzene*, $C_6H_2Br_2(SEt)_2$, which crystallises in long, silky needles, m. p. 58°.

Oxidation of the dimethyl ether (1 part) with perhydrol (1·5 parts) in glacial acetic acid solution at the ordinary temperature gives white needles of *phenylene*-1 : 3-*dimethyldisulphoxide*, $C_6H_4(SOMe)_2$, m. p. 131°. The corresponding *disulphone*, $C_6H_4(SO_2Me)_2$, is obtained when 3 parts of perhydrol are used and the reaction completed on the water-bath; it crystallises in white, glistening leaflets, and has m. p. 196—197°. The following compounds were obtained in a similar manner: *Phenylene*-1 : 3-*diethyldisulphoxide*, $C_6H_4(SOEt)_2$, is a colourless, oily liquid; the *disulphone*, $C_6H_4(SO_2Et)_2$, forms colourless, clear plates, m. p. 142°. *Phenylene*-1 : 3-*dibenzyldisulphoxide*, $C_6H_4(SO \cdot CH_2Ph)_2$, gives colourless, glistening crystals, m. p. 131°, whilst the *disulphone*, $C_6H_4(SO_2 \cdot CH_2Ph)_2$, forms tabular crystals, m. p. 229°. T. S. P.

4 : 4'-**Dithioldiphenyl.** THEODOR ZINCKE and ALEXANDER DAHM (*Ber.*, 1912, 45, 3457—3468).—4 : 4'-Dithioldiphenyl was obtained from benzidine by Leuckart's method (A., 1890, 603), except that the decomposition of the diazoxanthate was carried out in the presence of copper powder, whereby explosions are avoided and better yields obtained. From this compound a number of derivatives have been obtained.

By the action of chlorine on the solution of the dimercaptan or of its benzyl ether in carbon tetrachloride, 4 : 4'-dichlorothioldiphenyl (A., 1911, i, 369) is obtained. This compound loses chlorine on warming with glacial acetic acid, alcohol or dilute alkali, giving a compound which is probably the tetrasulphide, $S_2(C_6H_4 \cdot C_6H_4)_2S_2$. Oxidation with nitric acid or chlorine in glacial acetic acid solution gives the corresponding sulphonyl chloride. On heating with acetone, 4 : 4'-*diacetonylthioldiphenyl*, $C_{12}H_8(S \cdot CH_2Ac)_2$ is obtained in the form

of almost white needles, m. p. 165°. It can also be obtained from the dimercaptan and chloroacetone.

4 : 4'-Dimethylthioldiphenyl, $C_{12}H_8(SMe)_2$ (compare Leuckart, *loc. cit.*), is obtained by methylating the dimercaptan with methyl sulphate; m. p. 185°. The action of chlorine in glacial acetic acid solution gives the diphenyldichlorothiol, but in chloroform solution substitution occurs in the methyl groups, with the formation of 4 : 4'-*di-trichloromethylthioldiphenyl*, $C_{12}H_8(S\cdot CCl_3)_2$, white needles, m. p. 195°. When heated with aniline, triphenylguanidine and diphenyldithol are formed from the di-trichloro-compound.

4 : 4'-Diethylthioldiphenyl, $C_{12}H_8(SEt)_2$ (compare Leuckart, *loc. cit.*), is prepared similarly to the ethyl compound. The action of chlorine in chloroform solution gives a red oil. It forms a *tetrabromide* and *hexaiodide*.

4 : 4'-*Dibenzylthioldiphenyl*, $C_{12}H_8(S\cdot CH_2Ph)_2$, forms white, glistening, leaflets, m. p. 198—199°. Chlorination in chloroform solution gives benzylidene chloride and the dichlorothioldiphenyl.

4 : 4'-*Dimethylthioldiphenyl tetrabromide*, $C_{12}H_8(SMeBr_2)_2$, is obtained as a red, crystalline precipitate by the action of dry hydrogen bromide on the corresponding sulphoxide (see later) in chloroform solution; m. p. 130° (decomp.). Thiosulphate, sodium sulphite, or concentrated alkali eliminates bromine, whilst water or very dilute alkali regenerates the sulphoxide to some extent. The *hexabromide*, $C_{12}H_8(SMeBr_2)_2,Br_2$, prepared from the dimethyl ester by direct addition of bromine in chloroform solution, forms dark red crystals, and has m. p. 90° (decomp.). It behaves similarly to the tetrabromide towards bromine-eliminating agents. The *hexaiodide*, $C_{12}H_8(SMeI_2)_2,I_2$, is prepared similarly to the hexabromide, and has m. p. 198° (decomp.); it forms almost black crystals. It can also be obtained from the disulphoxide and hydrogen iodide. Iodine is eliminated by the usual agents, but the disulphoxide cannot be obtained from it.

4 : 4'-*Diphenyldimethyldisulphoxide*, $C_{12}H_8(SOMe)_2$, prepared from the dimethyl ether by oxidation with hydrogen peroxide or nitric acid (D 1·5), forms white leaflets, m. p. 195°. In glacial acetic acid solution it is reduced by hydrogen bromide or iodide, in contradistinction to its behaviour in chloroform solution (see above). Oxidation with perhydrol gives the *disulphone*, $C_{12}H_8(SO_2Me)_2$, white leaflets, m. p. 302°. The following sulphoxides and sulphones are prepared similarly : 4 : 4'-*Diphenyldiethyldisulphoxide*, $C_{12}H_8(SOEt)_2$, small, colourless needles, m. p. 134°; the *disulphone*, $C_{12}H_8(SO_2Et)_2$, forms white needles, m. p. 187°. 4 : 4'-*Diphenyldibenzyldisulphoxide*, $C_{12}H_8(SO\cdot CH_2Ph)_2$, consists of white needles, m. p. 243°, as also does the *disulphone*, $C_{12}H_8(SO_2\cdot CH_2Ph)_2$, m. p. 320°.   T. S. P.

The Autoxidation of Trinaphthylcarbinol. JULIUS SCHMIDLIN and MAXIMILIAN BERGMAN (*Ber.*, 1912, **45**, 3203—3205).—In reply to Tschitschibabin's criticism (A., 1911, i, 969) that of the two described isomerides of trinaphthylcarbinol (Schmidlin and Massini, A., 1909, i, 563) the more stable is in reality an oxidation product of the other, it is stated that this oxidation product (α-naphthyl-di-αα-naphthafluoryl alcohol) is a distinct substance, which causes a considerable depression

of the m. p. of the stable isomeride and is more easily obtained than the latter.

It has not hitherto been possible to prepare a triarylcarbinol containing only the diphenyl and naphthyl radicles ; bis-diphenylyl ketone and also esters of diphenylcarboxylic acid refuse to react with magnesium naphthyl iodide, also dinaphthyl ketone with magnesium diphenyl bromide. D. F. T.

Preparation of Acetal Condensation Derivatives from Polyhydroxy-alcohols with Aldehydes or Ketones. WALTER GERHARDT (D.R.-P. 253083. Compare Harnitzky and Mentschutkin, *Annalen*, 1865, **136**, 126).—Glycerol benzylidene ether,

$$C_6H_5\cdot CH{<}^O_O{>}C_3H_5\cdot OH,$$
has now been obtained with b. p. 280° and m. p. 84° (compare Fischer, A., 1894, i, 395) by heating glycerol and benzaldehyde together at 135—145°.

The *compound*, $C_{10}H_{12}O_2$, b. p. 113·5—115·5°/14 mm., is obtained from propylene glycol and benzaldehyde at 162° ; and the same aldehyde with trimethylene glycol furnishes *trimethylene glycol benzylidene ether*, $C_{12}H_{10}O_2$, m. p. 50°, b. p. 121—124°/15 mm.

Chlorohydrin benzylidene ether, $C_6H_5\cdot CH{:}O_2{:}C_3H_5Cl$, b. p. 144—146°/14 mm., is prepared from chlorohydrin and benzaldehyde ; glycerol and anisaldehyde yield the *compound*, $C_{11}H_{14}O_4$, b. p. 208—210°/18·5 mm., whilst the *compound*, $C_{11}H_{12}O_5$, m. p. 107—107·5°, is furnished by glycerol and piperonal ; and *acetophenone glycerol*, a viscous liquid, b. p. 156°/16 mm., is obtained from glycerol and acetophenone.

F. M. G. M.

Cubebin. IV. and V. EFISIO MAMELI (*Gazzetta*, 1912, **42**, ii, 546—550, 551—566. Compare A., 1908, i, 20 ; 1909, i, 503).— IV. iso*Cubebin ether* is obtained when cubebin is dissolved in the least quantity of concentrated acetic acid and treated with a small quantity of concentrated sulphuric acid ; on pouring the solution into water, the ether is precipitated. It forms colourless, acicular crystals, m. p. 157°, and has the composition and molecular weight required by the formula $C_{20}H_{18}O_5$. The substance is optically active, having $[\alpha]_D$ 26·02°. It reactions indicate that it is an internal ether.

Although cubebin ether is easily converted into cubebinol by reducing agents, *iso*cubebin ether resists such treatment, but it is converted into cubebinol when boiled with dilute acids.

V. This paper deals with hydroxycubebinic acid and some of its derivatives. The author has investigated the oxidation of cubebin and its derivatives by means of a large number of oxidising agents (hydrogen peroxide, bromine water, iodine water, Fehling's solution, silver oxide, Nessler's reagent, dilute nitric acid, lead nitrate, and lead peroxide, and hydrochloric acid), and has obtained in all cases results analogous to those previously obtained with other oxidising substances by himself and other observers. When, however, cubebin is suspended in strongly alkaline solution of sodium hypobromite at the ordinary temperature, a salt of a new acid, hydroxycubebinic acid, is produced.

The preparation is effected by keeping the reaction mixture in the dark for five or six days; the *sodium* salt which has separated (yield 93—96%) is collected and purified from admixed cubebin, which is insoluble in warm water. When the aqueous solution of this salt is treated with dilute sulphuric acid, the lactone, *cubebinolide*, $C_{20}H_{18}O_6$, is obtained; it forms colourless crystals, m. p. 63—64°, $[a]_D$ +33·69° (in chloroform). This substance behaves in all its reactions as a lactone of a monocarboxylic acid. It dissolves with difficulty in boiling alkalis, yielding the sodium and *potassium* salts of hydroxycubebinic acid. The sodium salt, $C_{20}H_{19}O_7Na$, forms acicular crystals, which melt in their water of crystallisation at 70°; the anhydrous salt has m. p. 205—207°; the salt has no pharmacological action. The other salts were obtained from the sodium salt. The *strontium, magnesium, zinc, cadmium, iron, uranium, copper, cobalt, nickel, lead, manganese, calcium,* $Ca(C_{20}H_{19}O_7)_2$, and *barium,* $Ba(C_{20}H_{19}O_7)_2$, salts were prepared. Indications of the existence of the free acid were observed, but it was not possible to isolate it.

When cubebinolide is treated with magnesium phenyl bromide, a *diphenyl* derivative is obtained, which is to be regarded as the product of dehydration of the glycol which would be expected. This substance crystallises in colourless leaflets, m. p. 136—137°, $[a]_D$ −178·78° (in chloroform), and has the probable formula $C_{32}H_{28}O_5$, although the analytical results do not agree with this very well.

When a methyl-alcoholic solution of cubebinolide is saturated with hydrogen chloride and kept in a sealed vessel, an *ester*, $C_{21}H_{21}O_6Cl$, is obtained; it crystallises in thin laminæ, m. p. 95°, $[a]_D$ +13·89°. When saponified (with strong alkali) it yields a salt of hydroxycubebinic acid.

Oxidation of the lactone with dilute nitric acid gives a *dinitro*-derivative, m. p. 183—184°. The action of bromine on an alcoholic solution of the lactone yields a *dibromo*-derivative, m. p. 137°.

The author gives provisional formulæ to illustrate possible modes of origin of the compounds above described, and their bearing on the constitution of cubebin.   R. V. S.

Hydrolysis of o-Acetoxybenzoates and the Preparation of Calcium o-Acetoxybenzoate. MICHAEL MÁTHÉ (*Chem. Zentr.*, 1912, ii, 431; from *Pharm. Post*, 1912, **45**, 474—476, 481—483).—The calcium salt was prepared by suspending slaked lime in alcohol and adding o-acetoxybenzoic acid, when the salt separated as a coagulated mass, which was washed with alcohol and dried at 40—60°. The sodium salt decomposes in aqueous solution more quickly than the lithium salt, and the latter at first more slowly, but eventually more quickly, than the calcium salt. The lithium salt decomposes when kept in dry powder, and also the calcium salt, but the latter only to a slight extent. In water, all three salts form acetic acid and the corresponding salicylate.   T. A. H.

The Action of Hydrochloric Acid and Potassium Hydroxide on the Lactam of Benzoyldehydracetic Acid. JOH. SCHÖTTLE and PAVEL IV. PETRENKO-KRITTSCHENKO (*Ber.*, 1912, **45**, 3229—3231. Compare A., 1911, i, 1020; 1912, i, 128).—It has already been

observed that the action of concentrated hydrochloric acid and sodium hydroxide solutions on the lactam of benzoyldehydracetic acid produces 2 : 6-diphenyl-4-pyridone-3-carboxylic acid and 2 : 6-diphenyl-4-pyridone respectively.

The action of hydrochloric acid in dilute solution in aqueous alcohol, or of dilute solution of potassium hydroxide in alcohol, gives rise to benzoyldehydracetic acid. This easy removal of nitrogen from the ring does not militate against the structure assumed for the lactam, as the alternative possibility of the position of the nitrogen atom in the side-chain would necessitate the assumption that ammonium chloride (in the action of concentrated solution of acid or alkali) can condense with benzoyldehydracetic acid—an assumption which is not in accord with experimental evidence.

The amide of dehydracetic acid, when heated in a sealed tube with hydrochloric acid at 180°, quantitatively eliminates a molecule of ammonia.   D. F. T.

Nitrogentisic Acids. ALFONS KLEMENC (*Monatsh.*, 1912, 33, 1243—1254).—The stability of gentisic acid (2 : 5-dihydroxybenzoic acid) is so increased by esterification that it can be successfully nitrated, especially if the hydroxyl groups are previously acetylated.

The methyl ester of diacetylgentisic acid, m. p. 62—63·5°, obtained by acetylation of methyl gentisate or by the action of diazomethane on diacetylgentisic acid, when nitrated with fuming nitric acid (D 1·52) and subsequently hydrolysed produces 3-*nitrogentisic acid*, a yellow powder, m. p. 230° (decomp.); *ammonium* salt, brown; the *silver* salt, a yellow, crystalline powder, on treatment with methyl iodide produces the *methyl* ester, yellow needles, m. p. 158° (decomp.), which can also be obtained by direct esterification of the acid by a methyl-alcoholic solution of hydrogen chloride.

Methyl 2-hydroxy-5-methoxybenzoate (Graebe and Martz, A., 1905, i, 702), when nitrated in acetic acid solution with fuming nitric acid, yields *methyl 3-nitro-2-hydroxy-5-methoxybenzoate*, yellow needles (from methyl alcohol), which change to leaflets, m. p. 138—139°; the *potassium* salt, yellow needles, obtained by hydrolysis, on acidification gives 3-*nitro-2-hydroxy-5-methoxybenzoic acid*, yellow needles, m. p. 181°.

Diazomethane acting in ethereal solution converts 3-nitrogentisic acid, and also 3-nitro-2-hydroxy-5-methoxybenzoic acid, into the *methyl* ester (colourless needles, m. p. 71—72°) of 3-*nitro-2 : 5-dimethoxybenzoic acid* (yellow needles, m. p. 181—183°), the acid being obtainable by hydrolysis.

The three nitro-acids described above all give characteristic colours when dissolved in potassium hydroxide solution.   D. F. T.

Preparation of Anthraquinonecarboxylic Acids. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 250742).—Anthraquinonecarboxylic acids can be readily prepared by oxidising the corresponding methyl-anthraquinones with nitrous fumes (NO_2 or N_2O_3) at a high tempera-ture in the presence of a suitable solvent, whilst some nitroanthra-quinones can be converted by the action of chlorine into the

corresponding chloroanthraquinones with elimination of the nitro-group.

1-*Chloroanthraquinone-2-carboxylic acid*, yellow needles, is obtained when 1-chloro-2-methylanthraquinone (25 parts) dissolved in 200 parts of trichlorobenzene is treated at 160° with the gases generated from a mixture of arsenious and nitric acids; and the required 1-chloro-2-methylanthraquinone is prepared by treating 1-nitro-2-methylanthraquinone with chlorine at 180°.

1 : 4-*Dichloroanthraquinone-2-carboxylic acid*, citron-yellow needles, is obtained from 1 : 4-dichloro-2-methylanthraquinone, whilst 2-methylanthraquinone furnishes *anthraquinone-2-carboxylic acid*.

F. M. G. M.

Benzalacetoneoxalic Acid [Benzylideneacetylpyruvic Acid]. OTTO MUMM (*Ber.*, 1912, **45**, 3236—3237).—The condensation product of pyruvic acid with benzaldehyde described by Mumm and Bergell (A., 1912, i, 936) as benzylideneacetylpyruvic acid is in reality the isomeric ketoacetylphenylparacone, $CH_3\cdot CO\cdot CH{<}^{CO\cdot CO}_{CHPh}{>}O$ (Ruhemann, T., 1906, **89**, 1236).

It is also formed from ethyl pyruvate and benzaldehyde, either from the sodium salt of the ester or from the free ester in presence of piperidine. E. F. A.

The Combination of Phenolcarboxylic Acids. FERDINAND MAUTHNER (*J. pr. Chem.*, 1912, [ii], **86**, 550—551).—A correction. The products obtained by hydrolysing the compounds described in previous communications (A., 1911, i, 725 ; 1912, i, 267) with alkalis fully confirms the constitutions there given, and, therefore, the author retracts the statements made in his last paper (A., 1912, i, 858).

F. B.

Isomeric and Tautomeric Organo-magnesium Compounds. JULIUS SCHMIDLIN and ANTONIO GARCIA-BANÙS (*Ber.*, 1912, **45**, 3193—3203).—The earlier explanation of the different behaviour of aromatic aldehydes with ordinary and previously heated solutions of magnesium triphenylmethyl chloride (Schmidlin, A., 1906, i, 392 ; 1907, i, 26, 601 ; 1908, i, 239) is adhered to in spite of the criticism of Tschitschibabin (A., 1909, i, 778). In refutation of the latter's criticism, it is stated that his experiments were not of a nature to decide the question, and it is further shown that, although magnesium benzyl chloride cannot be separated into two isomerides, the solution behaves as if it contained a tautomeric mixture of two isomerides, which, it is suggested, represent the normal and quinonoid configurations already assumed for the two forms of magnesium triphenylmethyl chloride.

When magnesium benzyl chloride solution in ether is treated with benzaldehyde, the latter being added in drops, the product is $\alpha\beta$-diphenylethyl alcohol, $CH_2Ph\cdot CHPh\cdot OH$. During the progress of the reaction, the Grignard reagent, which is believed to be an equilibrium mixture of the forms $CH_2{:}C_6H_4{<}^{H}_{MgCl}$ and $CH_2Ph\cdot MgCl$,

has time to rearrange so as to give a theoretical yield of the diphenyl-
ethyl alcohol produced by the latter form. If, however, the Grignard
reagent is gradually introduced into the ethereal solution of
benzaldehyde, both forms enter into reaction, and the product is a
mixture of the above diphenylethyl alcohol with 1 : 3-*diphenyl-*
3 : 4-*dihydro*-2 : 1-*benzopyran* (*diphenylisochroman*),

$$C_6H_4{<}{\stackrel{CHPh\cdot O}{CH_2{-}CHPh}},$$
prismatic needles, m. p. 111·5° (corr.), b. p. 237°/9 mm., which dissolve
in concentrated sulphuric acid to a green solution; on oxidation with
potassium permanganate it gives *o*-benzoylbenzoic acid and benzoic
acid, whilst chromic acid produces anthraquinone and benzoic acid.
In the preparation of the above diphenyldihydrobenzopyran, there
was occasionally obtained 1 : 3-*diphenyl*-2 : 1-*benzopyran* (*diphenyliso-*
chromene), $C_6H_4{<}{\stackrel{CHPh\cdot O}{CH{=}CPh}}$, colourless needles, m. p. 125—126°
(corr.); this decolorises bromine and potassium permanganate
solutions, and gives a colourless solution in sulphuric acid; chromic
acid gives the same oxidation products as with the dihydro-compound,
whilst reduction by hydrogen and platinum-black produces the
dihydro-derivative.

With other reagents, the magnesium benzyl chloride undergoes
reaction merely through one of its isomerides; thus the action of
carbon dioxide affects only the normal compound, whereas the
formation of *o*-tolyl alcohol from formaldehyde (Tiffeneau and
Delange, A., 1904, i, 48) depends on the reaction taking place with
the quinonoid isomeride.   D. F. T.

The Action of Ultraviolet Light on *o*-, *m*-, and *p*-Nitro-
benzaldehyde and on Benzaldehyde. ANTON KAILAN (*Monatsh.*,
1912, 33, 1305—1327).—Under the action of ultraviolet light, *o*-nitro-
benzaldehyde, both in alcoholic and benzene solutions, is slowly trans-
formed into *o*-nitrosobenzoic acid (compare Ciamician and Silber, A.,
1901, i, 547), the reaction taking place quicker in quartz than in glass
vessels. The formation of acid from benzaldehyde takes place
similarly. With both aldehydes the acid formation takes place more
rapidly in benzene than in alcoholic solutions. The velocity of
reaction increases with increase in concentration of the aldehyde, but
proportionality does not exist, the increase in velocity being less than
would be expected. Under similar conditions the amount of acid
formed from the *o*-nitrobenzaldehyde is about twice as great as from
the benzaldehyde. When the distance between the source of ultra-
violet light (a mercury lamp) and the reaction vessel is increased, the
diminution in reaction velocity is greater than would be expected from
the inverse-square law. During the reaction a very considerable
portion of the active rays is absorbed.

m- and *p*-Nitrobenzaldehydes, either as the solids or in solution, are
hardly affected by ultraviolet light, the formation of acid being
extremely small. Both solid *o*-nitrobenzaldehyde and liquid benz-
aldehyde are acted on to a considerable extent, in one case 87% of the
benzaldehyde being converted into benzoic acid.

The formation of acid is due principally to oxidation by the oxygen of the air, or by ozone formed by the ultraviolet light; the reaction expressed by the equation : $2Ph \cdot COH + H_2O = Ph \cdot CH_2OH + Ph \cdot CO_2H$, if it takes place at all, plays only a subsidiary part.

In absolute alcoholic solution benzoic acid is not esterified to any appreciable extent under the conditions of experiment, nor does it have any accelerating action on the oxidation of the benzaldehyde, although hydrions, when present in great concentration, may exert such an action.

The temperature-coefficient of the above reactions is very small, as is usually the case in photochemical actions.   T. S. P.

New Synthesis of o-Aldehydophenylnitrosohydroxylamine. OSKAR BAUDISCH (*Ber.*, 1912, **45**, 3429—3430).—A solution of o-nitro-benzaldehyde in 96% alcohol (10 vol.) is diluted with 5 vol. of water, treated with 3 vol. of amyl nitrite and 3 vol. of concentrated aqueous ammonia, and then gradually with zinc dust. The reaction is complete after about fifteen minutes. The mixture is treated with an excess of aqueous copper sulphate, and dilute hydrochloric acid is added carefully with cooling. From the still alkaline solution is obtained a brown, flocculent precipitate, which is removed. The filtrate is rendered distinctly acid, whereby the copper derivative of o-aldehydophenyl-nitrosohydroxylamine is precipitated. After being washed with acetone, the copper salt is converted by aqueous alcoholic potassium hydroxide into the potassium salt, from which o-aldehydophenylnitroso-hydroxylamine, m. p. 52·5°, is liberated by metaphosphoric acid.
                                                                    C. S.

Chemical Action of Light. II. Photo-Oxidation of the Aldehyde Group. I. Terephthalaldehyde. HERMANN SUIDA (*Monatsh.*, 1912, **33**, 1173—1187. Compare A., 1912, i, 117).— Although terephthalaldehyde is very stable in the solid state and in solution in benzene in the dark, its solution undergoes rapid atmospheric oxidation when illuminated by a mercury lamp, and a white, crystalline deposit is formed ; the deposit consists of terephthal-aldehydic acid to the extent of roughly two-thirds, the remainder being terephthalic acid ; the solution from which the crystals have separated gives a peroxide reaction with acidified potassium iodide solution. This oxidation of terephthalaldehyde appears not to occur at all if light is excluded, and it is not accelerated by the presence of nitrobenzene, this substance, indeed, exerting a hindering effect ; a comparison with benzaldehyde seems to indicate that, assuming the supply of oxygen by diffusion to be more than sufficient, the oxidation velocity of each aldehyde group in terephthaldehyde is considerably diminished by the presence of a similar group in the para-position. By interposing solutions of potassium chromate and of quinine sulphate between the solution and the source of light, it is discovered that the effect is mainly due to the ultra-violet rays, but that yellow and red light can cause the oxidation to occur, although only very feebly. Spectrographic examination indicates that the effective rays are from 400 to $300 \mu\mu$.
                                                                    D. F. T.

Catalytic Reduction. VII. The Preparation and Application of Colloidal Platinum Metals. ALADÁR SKITA and W. A. MEYER (*Ber.*, 1912, 45, 3579—3589).—When submitted to the action of free hydrogen, an aqueous alcoholic solution containing an unsaturated aldehyde or ketone with a little palladious chloride and gum arabic undergoes reduction ; colloidal palladium is first formed, which then catalytically accelerates the hydrogenation of the ethylenic linking (Skita, A., 1909, i, 479). If the ethylenic substance has not contain a ketonic or aldehydic group, colloidal palladium is not obtained, but precipitated metal, which, however, is sufficient to aid the reduction of camphene to dihydrocamphene, and of β-phenylvinyl acetate to *β-phenylethyl acetate*, b. p. 109—112°/13 mm., although it fails to reduce double bonds in aromatic nuclei. This action of the carbonyl group in aiding the formation of colloidal palladium is probably due to the formation of a double compound of the ketone or aldehyde with the greater portion of the metallic chloride present (compare Zeisse, *Annalen*, 1840, 33, 29) ; under such conditions it is probable that colloidal particles are first formed which can cause the separation of the rest of the metal in the same form. This is confirmed by the behaviour at the ordinary temperature of a solution of palladious chloride and gum arabic, which, after the addition of a little colloidal palladium, is rapidly reduced by hydrogen to the colloidal metal, whereas if treated directly with hydrogen the metal is slowly precipitated in an insoluble form ; this effect is not merely due to the prevention of supersaturation (Zsigmondy, A., 1906, ii, 679), but is also in part catalytic.

A colloidal solution of palladium can also be obtained by the action of hydrogen on a hot aqueous solution of palladious chloride containing gum arabic ; when a mixture of this solution with an alcoholic feebly acid solution of piperine was treated with hydrogen, tetrahydropiperine (Skita and Franck, A., 1911, i, 1017) was produced.

Solutions of palladious chloride and of potassium platinosochloride containing gum arabic, when treated with sodium carbonate, give palladious and platinous hydroxides in a colloidal condition ; careful evaporation in a vacuum, after dialysis, gives a residue of brown palladious hydroxide or black platinous hydroxide consisting of scales, which readily dissolve in water again. These colloidal hydroxides are well suited to reduction processes, for example, hydrogen reduced an aqueous alcoholic solution of pinene containing a little palladium hydroxide to pinane, and a solution of phorone containing a little platinum hydroxide readily absorbed an amount of hydrogen corresponding with two ethylenic linkings.

Colloidal palladium hydroxide solutions when shaken with hydrogen are reduced to colloidal palladium, and on evaporation in a vacuum black scales are obtained which readily re-dissolve in water; black scales of colloidal platinum can be similarly obtained. These, which can also be prepared directly by reduction of the corresponding chlorides, are again suitable for reduction experiments, *o*-nitroacetophenone and nitrobenzene being easily reduced to the corresponding amino-compounds.

The most satisfactory method for the hydrogenation of an un-

saturated compound is to add to the solution of platinum chloride and gum arabic a trace of a colloidal palladium or platinum solution, and then to act with hydrogen ; the unsaturated substance which may be present from the commencement or introduced later is then easily reduced, for example, quinine yields dihydroquinine, whilst diacetyl-morphine gives *diacetyldihydromorphine,* needles, m. p. 158° (*hydro-chloride,* needles, m. p. above 300°), and cinnamic acid yields β-phenyl-propionic acid.   D. F. T.

Catalytic Reduction. VIII. Hydrogenation of Aldehydes and Ketones, and of Aromatic and Heterocyclic Substances in Colloidal Solutions. ALADAR SKITA and W. A. MEYER (*Ber* , 1912, **45**. 3589—3595. Compare preceding abstract).—It has already been observed that hydrogenation occurs more readily in certain solvents than in others (Fokin, A., 1907, i, 819), and that acetic acid is so suitable that in the presence of platinum black even aromatic substances can be reduced (Willstätter and Hatt, A., 1912, i, 545). By using a colloidal solution of platinum, prepared by one of the methods described (preceding abstract), and applying acetic acid as solvent, it is found possible with hydrogen under an additional pressure of one atmosphere, to reduce toluene to methyl*cyclo*hexane, benzoic acid to *cyclo*hexanecarboxylic acid, naphthalene to decahydro-naphthalene, pyridine to piperidine, heptaldehyde to heptyl alcohol, dihydro*iso*phorone to *trans*-dihydro*iso*phorol, and benzene to *cyclo*-hexane ; in the last two cases only a trace of colloidal platinum was taken with a solution of the substance for reduction, together with chloroplatinic acid, so that the treatment with hydrogen first produced the catalyst, and then reduced the organic substance; the reduction processes generally occupied one to three hours. Quinoline, however, required longer treatment with a rather higher pressure of hydrogen for reduction to decahydroquinoline, and by checking the reduction at the right stage, tetrahydroquinoline could be obtained. A descrip-tion of the apparatus employed is given.

It was not found possible to replace gum arabic satisfactorily by any other protecting colloid.   D. F. T.

Condensation Products of Cyclic Ketones with Acetone. OTTO WALLACH and W. VON RECHENBERG (*Chem. Zentr.,* 1912, ii, 923—924; from *Nachr. K. Ges. Wiss. Gött.,* 1912, 442—445).—Further investigation of the condensation of acetone with 1 : 3-methyl-*cyclo*hexanone (A., 1896, i, 572 ; 1897, i, 425) shows that condensation takes place between the O-atom of the cyclic ketone and hydrogen from the acetone, with the production of compounds having a :CO group in the side-chain, which can be reduced to saturated ketones of the type R·CH₂·COMe, where R is a cyclic radicle. The position of the ethylenic linking is uncertain, but it is probably cyclic.

1:3-*Methylcyclohexylacetone*, b.p. 211·5—212°, D^{25}_{5} 0·8915, n^{m}_{D} 1·4496, obtained by reducing the methyl*cyclo*hexenylacetone produced by condensing 1-methyl*cyclo*hexan-3-one with acetone (*loc. cit.*), is lævo-rotatory, resembles other extra-cyclic ketones in aroma, gives a *semi-*

carbazone, m. p. 154°, and on oxidation with sodium hypobromite yields
1 : 3-methyl*cyclo*hexylacetic acid.　1 : 4-*Methylcyclohexenylacetone*, b. p.
216—217°, D^{21} 0·916, n_D^m 1·4672, has an anise odour, gives a *semi-
carbazone*, m. p. 122—123°, and a liquid *oxime*.　On reduction it yields
1 : 4-*methylcyclohexylacetone*, b. p. 214—215°, D^{21} 0·8930, n_D^m 1·4499.
The latter gives a *semicarbazone*, m. p. 166°, and is oxidised by sodium
hypobromite to 1 : 4-methyl*cyclo*hexylacetic acid.　　　　　　T. A. H.

Action of an Alcoholic Solution of Potassium Hydroxide
on Ketones. II.　Pieter J. Montagne and Jacob Moll van
Charante (*Rec. trav. chim.*, 1912, 31, 298—349.　Compare A., 1908,
i, 988).—The action of alcoholic potash on further derivatives of
benzophenone is described.　It is found that the introduction of an
amino-group into any position in the ring entirely prevents the
reduction to a benzhydrol, but that the presence of methyl, chlorine,
or bromine in the *para*-position, or of chlorine in the *ortho*-position, is
without influence on the reduction.　In the case of the bromo-deriv-
atives it was previously found that 2 : 4 : 6-tribromobenzophenone is
not only reduced, but that it also loses the bromine atoms in 2 and 6
(A., 1910, i, 42).　Studying this detaching influence of the –COPh
group further, it is found that the elimination of bromine occurs
readily in the case of *o*-bromobenzophenone, to a slight extent with
the para-compound, and to a still smaller extent, but certainly, with
the meta-derivative.　The –CHPh·OH group, on the contrary, has no
such detaching influence, the substituted benzhydrols remaining
entirely unchanged when heated with alcoholic potash ; only in the
case of the 4 : 4'-dibromobenzhydrol was there any trace of halogen
removed.　The following benzophenones have been studied : 2-, 3-, and
4-chloro-, 4 : 4'-dichloro-, 2-, 3-, and 4-bromo-, 2 : 4-, 2 : 6-, and 4 : 4'-
dibromo-, 4-iodo-, 2-amino-, 2 : 2'-diamino-, 4 : 4'-didimethylamino-
(Michler's ketone), 2- and 3-methyl-.　Many of these have been
described by Montagne and Koopal (see Koopal, Thesis).

　　2 : 4-Dibromobenzophenone was obtained by the action of benzoyl
chloride and aluminium chloride on 1 : 3-dibromobenzene (Boeseken,
A., 1908, i, 189) and also synthesised as follows : Acetanilide was
converted into 2 : 4-dibromoacetanilide, not by Chattaway's method
(A., 1900, i, 152), since that yielded only *p*-bromoacetanilide, but
according to Mannino and Donato (A., 1908, i, 826).　This was
saponified by 10% potassium hydroxide, and the 2 : 4-dibromoaniline
diazotised.　With amyl nitrite, nitrous acid, or sodium nitrite and
dilute sulphuric acid, a varying quantity of 2 : 4 : 2' : 4'-tetrabromo-
diazoaminobenzene crystallised out, but on warming with water the
mixture gave a good yield of 1 : 3-dibromobenzene.　When mixed
with potassium nitrite and added to concentrated nitric acid, the
formation of a diazoamino compound was prevented (compare O. N.
Witt, A., 1909, i, 855), and on warming the diluted diazotised liquid
with a mixture of copper sulphate and potassium cyanide the
2 : 4-dibromobenzonitrile was obtained.　This was saponified and the
acid converted into the chloride, which with benzene and aluminium
chloride gave the 2 : 4-dibromobenzophenone.　From the mother
liquors of this compound a small amount of 2 : 6-dibromobenzo-

phenone was recovered, the two bromine atoms exerting no steric hindrance, which confirms the author's experience that the Friedel and Crafts's reaction on halogenated benzenes gives rise to ortho- as well as to para-substitution.

2 : 6-Dibromobenzophenone was also synthesised. Sulphanilic acid was converted into dibromoaniline (Orton and Pearson, T., 1908, 93, 735), and this was diazotised as above and converted into 2 : 6-dibromobenzonitrile, which was saponified by 65% sulphuric acid. The amide, m. p. 208·5°, was further treated with 90% sulphuric acid, and the 2 : 6-dibromobenzoic acid was converted into 2 : 6-dibromobenzoyl chloride and this into 2 : 6-*dibromobenzophenone*, $C_6H_3Br_2 \cdot COPh$, which crystallises in very long needles, m. p. 121·5°, b. p. 381°.

4-Aminobenzophenone, m. p. 124°, obtained by the reduction of 4-nitrobenzophenone (Shröter, A., 1909, i, 773) was found to remain unchanged by acetic acid, and was thus distinguished from 4-aminobenzhydrol, m. p. 121°, since the latter gives an acetyl compound, m. p. 153° (Doebner, A., 1882, 507). New benzhydrols obtained by the action of alcoholic potash on the benzophenones are 3-*bromobenzhydrol*, $C_6H_4Br \cdot CHPh \cdot OH$, m. p. 43°, and 3-*methylbenzhydrol*, $C_6H_4Me \cdot CHPh \cdot OH$, slender needles, m. p. 53°.

Detailed crystallographic measurements of the following substances have been made : 4-bromoacetanilide, 2 : 4-dibromoacetanilide, 2 : 4-dibromoaniline, 2 :4-dibromobenzophenone, 2 : 6-dibromobenzamide, and 2-nitrobenzophenone.   J. C. W.

Conversion of Distyryl Ketone into 2 : 6-Diphenylpyrone. DANIEL VORLÄNDER and G. A. MEYER (*Ber*, 1912, 45, 3355—3358).— Distyryl ketone tetrabromide (Claisen and Claparède, A., 1882, 511) when heated in alcoholic solution with a quadrimolecular quantity of potassium hydroxide is converted into a viscous oil, probably the diethoxy-compound, $CO(CH{:}CPh \cdot OEt)$; the substance gives a blood-red solution in sulphuric acid and a gradual brownish-black coloration with ferric chloride solution. When it is heated with hydrochloric acid (D 1·1) under reflux condenser for several hours a mixture of 2 : 6-diphenylpyrone, needles, m. p. 139—140°, with much resinous matter is produced.   D. F. T.

Elimination of Hydrogen from Aromatic Nuclei and Union of the Latter by means of Aluminium Chloride. ROLAND SCHOLL and CHRISTIAN SEER (*Annalen*, 1912, 394, 111—177).— Isolated instances of the union of aromatic nuclei by means of aluminium chloride at elevated temperatures are known, for example, the formation of perylene from 1 : 1'-dinaphthyl (Scholl, Seer, and Weitzenböck, A., 1910, i, 616), of flavanthrene from 2-aminoanthraquinone (Scholl, A., 1907, i, 540), and of *meso*-naphthadianthrone from *meso*-benzdianthrone (Scholl and Mansfeld, A., 1910, i, 494). The authors have now examined this reaction more fully, and find that, by means of anhydrous aluminium chloride at 80—140°, aromatic nuclei can be very satisfactorily united, particularly in the case of aromatic

ketones, where the elimination of the hydrogen is accompanied by the formation of new rings ; thus, 1 : 9-benzanthrone is obtained in 76% yield by heating phenyl a-naphthyl ketone and anhydrous aluminium chloride (5 pts.) at 150° during two and a-half hours. In a similar manner, o-tolyl a-naphthyl ketone yields *5-methyl-1 : 9-benzanthrone* (annexed formula), m. p. 167—168°, yellow needles ; *m*-tolyl a-naphthyl ketone yields 6-*methyl*-1 : *9-benzanthrone*, m. p. 169·5°, yellow needles ; *p* tolyl a-naphthyl ketone yields 7-*methyl*-1 : 9-*benzanthrone*, m. p. 158—159°, yellow needles; *p*-diphenylyl a-naphthyl ketone yields 7-*phenyl*-1 : 9-*benzanthrone*, m. p. 170—171°, yellowish-brown leaflets ; phenyl a-4-hydroxynaphthyl ketone yields 2-*hydroxy*-1 : 9-*benzanthrone*, m. p. 304°, dark red needles (*benzoyl* derivative, m. p. 236°, golden-yellow needles). In the last preparation, 2-*hydroxydihydro*-1 : 9-*benzanthrone*, m. p. 142—143°, yellowish-brown needles, is first formed, it is converted into 2-hydroxy-1 : 9-benzanthrone by prolonged heating or by passing oxygen through its solution in hot aqueous sodium hydroxide.
The interaction of naphthalene, o-toluoyl chloride, and aluminium chloride in carbon disulphide leads to the formation of o *tolyl a-naphthyl ketone*, $C_{10}H_7 \cdot CO \cdot C_6H_4Me$, m. p. 64°, b. p. 365—375°. By similar methods, m-*tolyl a-naphthyl ketone*, m. p. 74—75°, and p-*tolyl a-naphthyl ketone*, m. p. 85°, have been prepared. p-*Diphenylyl a-naphthyl ketone*, $C_{10}H_7 \cdot CO \cdot C_6H_4Ph$, m. p. 136—137°, is obtained in a similar manner from a-naphthoyl chloride and diphenyl, or from naphthalene and the *chloride*, m. p. 114—115°, colourless needles, of diphenyl-4-carboxylic acid. *Phenyl a-4-hydroxynaphthyl ketone*, $OH \cdot C_{10}H_6 \cdot COPh$, m. p 164—165°, is obtained from a naphthol and benzoyl chloride by Doebner's method.

o-a-Naphthoylbenzoic acid yields naphthanthraquinone, not the expected 1 : 9-benzanthrone-5-carboxylic acid, by heating with aluminium chloride.

[With Otto von Seybel.]—The interaction of the chloride of anthraquinone-2 carboxylic acid, naphthalene, and aluminium chloride in nitrobenzene at 75—80° for ten hours leads to the formation of a mixture of a-*naphthyl 2-anthraquinonyl ketone*,

$$C_6H_4 {<}^{CO}_{CO}{>} C_6H_3 \cdot CO \cdot C_{10}H_7,$$
m. p. 166—166·5°, light brown leaflets, and the β-*isomeride*, m. p. 176—177°, citron-yellow needles, which is separated by repeated crystallisation from glacial acetic acid and from pyridine. By heating with aluminium chloride at 100—140° for one hour and again at 140—145° for another hour, the former yields 6 : 7-*phthaloyl*-1 : 9-*benzanthrone* (annexed formula), m. p. 325—326°, dark yellow needles, which, unlike the a-naphthyl anthraquinonyl ketone, forms with alkaline sodium hyposulphite a dark green vat producing on unmordanted cotton green tones changing to yellow in air. The constitution of the
phthaloylbenzanthrone is proved by oxidation with chromic acid, whereby 2 : 3-*phthaloylanthraquinone-5-carboxylic acid*,

$$C_6H_4 <^{CO}_{CO}> C_6H_2 <^{CO}_{CO}> C_6H_3 \cdot CO_2H,$$
m. p. 338° (decomp.), microcrystalline, yellow needles, is obtained, which is converted by sublimation into Philippi's 2 : 3-phthaloyl-anthraquinone (A., 1911, i, 793). Phthaloylanthraquinonecarboxylic acid forms a greenish-yellow *sodium* salt, which forms with hot alkaline sodium hyposulphite a violet, and finally an orange, solution, changing to blue in air; this solution produces on unmordanted cotton a blue colour which becomes red by treatment with acids.

The interaction of pyrene, benzoyl chloride (rather more than 1 mol.), and aluminium chloride in carbon disulphide for twelve hours at the ordinary temperature, and then for an equal period on the water-bath, leads to the formation of 3-*benzoylpyrene*, m. p. 124—125°, yellow crystals, which is purified by means of the *picrate*, $C_{29}H_{17}O_8N_3$, m. p. 157°, orange needles. By using two or more mols. of benzoyl chloride, a mixture of di- and tri-benzoyl-pyrene is obtained, which is separated readily owing to the slight solubility of the latter in glacial acetic acid. 3 : 5 : 8 *Tri-benzoylpyrene* (annexed formula), m p. 239—240°, crystallises in yellow needles. 3 : 8-*Dibenzoylpyrene*, m. p. 158—160°, slender, yellow needles, yields pyrenequinone by oxidation with aqueous potassium dichromate and sulphuric and acetic acids, and is converted into pyranthrone when mixed with aluminium chloride, placed in a bath previously heated to 155—160°, and kept there for one hour (if the heating is effected gradually, the benzoyl groups are eliminated before the benzanthrone rings are formed). This formation of pyranthrone establishes the direct relation of the substance to pyrene, and also proves the orientation of the benzoyl groups in the dibenzoylpyrene. 3 : 5 : 8-Tribenzoylpyrene is converted into 3-*benzoylpyranthrone*, red-dish-brown, metallic needles, in a similar manner; at a slightly higher temperature, 165—170°, the benzoyl group is eliminated and pyr-anthrone is formed. The interaction of pyrene, α-naphthoyl chloride, and aluminium chloride in carbon disulphide leads to the formation of a nearly quantitative yield of a mixture of 3 : 8- and 3 : 10-di-α-naphthoylpyrene, which is separated by boiling glacial acetic acid, in which the former is in-soluble. 3 : 8-*Di-α-naphthoylpyrene*,
$$C_{38}H_{22}O_2,$$
m. p. 271·5—273°, crystallises in micro-scopic, yellow leaflets; the 3 : 10-*isomeride*, m. p. 219—220°, in yellow leaflets. The former and aluminium¹ chloride at 140° for forty minutes yield 5 : 6 : 5′ : 6′-*dibenzpyranthrone* (annexed formula), a brown powder, which forms in hot alkaline sodium hyposulphite a sparingly soluble vat, by which unmordanted cotton is dyed blue, changing to orange-

red in air. In a similar manner, pyrene, β-naphthoyl chloride, and aluminium chloride yield 3 : 10-*di-β-naphthoylpyrene*, m. p. 195·5—197°, yellow crystals (purified by means of the orange yellow *picrate*), and 3 : 8-*di-β-naphthoylpyrene*, m. p. 289°, flattened, yellow needles. The latter and aluminium chloride at 145—155° yield 7 : 8 : 7′ : 8′-*dibenz-pyranthrone*, a brown, indistinctly crystalline powder with green shimmer, which forms a vat behaving like that of the preceding isomeride.

It will be noticed that the action of the preceding acyl chlorides on pyrene in the presence of aluminium chloride yields in each case a pair of diacylpyrenes. One of these is undoubtedly the 3 : 8-diacylpyrene, since it is converted into benz-(or dibenz-)pyranthrone by aluminium chloride. It is known that hydrocarbons such as anthracene and phenanthrene, which are easily oxidised to quinones, are attacked in the Friedel-Crafts reaction by the acid chloride or anhydride in the same positions as by the oxidising agent in the formation of the quinone. Consequently it is probable that pyrene, which forms 3 : 8-diacylpyrenes in the Friedel-Crafts reaction, yields 3 : 8-pyrene-quinone, not 3 : 10-pyrenequinone (Goldschmiedt, A., 1907, i, 310), by oxidation.

The constitution of violanthrone (Bally's violanthrene, A., 1905, i, 237) has been proved by the formation of the substance from 4 : 4′-dibenzoyl-αα-dinaphthyl and aluminium chloride at 95—100°.
The interaction of naphthalene, pyromucyl chloride, and aluminium chloride in carbon disulphide leads to the formation of (impure) α-*furyl* α-*naphthyl ketone*, $C_4OH_3 \cdot CO \cdot C_{10}H_7$, b. p. 360—365°, which reacts with aluminium chloride to form a brown substance from which individual products have not been isolated. In a similar manner, naphthalene and the chloride of thiophen-2-carboxylic acid, or thiophen and α-naphthoyl chloride, yield α-*thienyl* α-*naphthyl ketone*, $C_4SH_3 \cdot CO \cdot C_{10}H_7$, m. p. 68—69°, b. p. 383°, almost colourless needles, which is converted by aluminium chloride at 140—144° into *benzthiophanthrone*-9 (annexed formula), a brown, crystalline powder; this sinters at 210°, but is not fused at 250°, and yields by fusion with alcoholic potassium hydroxide a dye which is probably the analogue, $C_{30}H_{12}O_2S_2$, of violanthrone.
The interaction of pyrene, the chloride of thiophen-2-carboxylic acid, and aluminium chloride in carbon disulphide leads to the formation of 3 : 8-*di-α-thiophenoyl-pyrene*, $C_{26}H_{14}O_2S_2$, m. p. 278—279°, elongated, yellow leaflets, and 3 : 10-*di-α-thio-phenoylpyrene*, m. p. 191—192°, yellow leaflets ; the former and aluminium chloride at 150—158° yield *pyrthiophanthrone* (annexed formula), microscopic, reddish-brown needles. C. S.

Chalkones and Hydrochalkones. II. Guido Bargellini and Mina Finkelstein (*Gazzetta*, 1912, 42, ii, 417—426. Compare Bargellini and Bini, A., 1912, i, 118).—The present paper describes

the reduction of four chalkones to the corresponding hydrochalkones by means of hydrogen in the presence of platinum black or palladium black.

$2' : 4' : 5'$-Trimethoxychalkone (compare Bargellini and Avrutin, A., 1911, i, 68) is conveniently prepared by the original method of preparation of chalkones (Stockhausen and Gattermann, A., 1893, i, 163). If, however, the heating of the mixture of hydroxyquinol trimethyl ether, cinnamyl chloride, and aluminium chloride is prolonged to ten or twelve hours, the principal product is a *substance*, $C_{27}H_{30}O_7$, which forms colourless needles, m. p. 127—128°. This compound dissolves in concentrated sulphuric acid, giving a pale yellow coloration, and does not react with bromine; it probably has the annexed constitution.
OMe   OMe

OMe⟨   ⟩·CO·CH$_2$·CHPh·⟨   ⟩OMe

OMe   OMe

$2' : 4' : 5'$-*Trimethoxyhydro-chalkone*, $C_{18}H_{20}O_4$, crystallises in colourless needles, m. p. 105—107°; it dissolves in concentrated sulphuric acid, giving a pale yellow coloration.

$3 : 4 : 2' : 4' : 5'$-*Pentamethoxyhydrochalkone*, $C_{20}H_{24}O_6$, forms colourless needles, m. p. 115—117°; it dissolves in concentrated sulphuric acid, giving a pale yellow coloration.

$2'$-*Hydroxy*-$4 : 4'$-*dimethoxyhydrochalkone*, $C_{17}H_{18}O_4$, crystallises in colourless needles, m. p. 58—60°.

$2'$-*Hydroxy*-$3 : 4 : 4'$-*trimethoxyhydrochalkone*, $C_{18}H_{20}O_5$, crystallises in colourless needles, m. p. 78—79°, and dissolves in concentrated sulphuric acid, giving a pale yellow coloration.

Attempts to reduce esperitin were unsuccessful, possibly owing to the hindering action of the free phenolic hydroxyl groups, or perhaps owing to some influence of the solvent.   R. V. S.

Phenylhydroxyketoperinaphthindene. MARCELLO CESARIS (*Gazzetta*, 1912, 42, ii, 453—472).—When phenylacetic acid, naphthalic anhydride, and potassium acetate are heated at 230° for two hours, 1-hydroxy-3-keto-2-phenylperinaphthindene (annexed formula) is formed; it crystallises in iridescent, orange-yellow scales, m. p. 218°, and dissolves in concentrated sulphuric acid, giving an intense yellow coloration. The substance dissolves in alkalis, and is reprecipitated by acids. The *acetyl* derivative, $C_{19}H_{11}O_2Ac$, forms deep yellow needles, m. p. 172—175°. Bromination of hydroxyketophenylperinaphthindene in anhydrous solvents (such as chloroform) yields an unstable *additive product* of the probable formula $C_{19}H_{12}O_2Br_2,HBr$. By the action of water on this compound, or by bromination in aqueous solvents, 2-*bromo*-1 : 3-*diketo*-2-*phenylperinaphthindene* (annexed formula) is obtained; it forms prisms or needles, m. p. 198°. The *anilide*, $C_{19}H_{11}O_2\cdot NHPh$, prepared from the bromo-derivative, crystallises in golden-yellow scales, m. p. 225—227°. When the bromo-derivative is treated with alkalis, hydroxyketophenylperinaphthindene
is obtained. The action of hydrogen bromide on hydroxyketophenylperinaphthindene (in chloroform) yields an unstable *compound*, $C_{19}H_{12}O_2HBr$, which begins to melt at 90° and is completely melted at 210°.

Cautious oxidation of hydroxyketophenylperinaphthindene with permanganate yields naphthalic acid, benzoic acid, and traces of an *acid* crystallising in colourless needles, m. p. about 200—202°. Oxidation with potassium dichromate in acetic acid yields a neutral substance, $C_{38}H_{22}O_4$, to which the annexed structure of *bis diketophenylperinaphthindene* is ascribed; it is a straw-coloured, crystalline powder, m. p. about 235—236° (decomp), and it dissolves in concentrated sulphuric acid, giving an intense orange-red coloration.　　　R. V. S.
Preparation of α-Chloroanthraquinone. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 252578).—When α-nitroanthraquinone (or its derivatives) is treated with chlorine, this element displaces the α-nitrogroup. Moreover, when 1-nitro-2-methylanthraquinone is similarly treated at high temperatures it furnishes ω-di- with some ω-mono- and ω-tri-chloro-derivatives. 1-Chloroanthraquinone is obtained (in satisfactory yield) when 1-nitroanthraquinone (80 parts) in 400 parts of trichlorobenzene is treated at 160—165° with a stream of chlorine; 1 : 5-dinitroanthraquinone at 190° furnishes 1 : 5-dichloroanthraquinone, and at 160—180° 1-nitro-2-methylanthraquinone yields chiefly ω-1-trichloro-2-methylanthraquinone.　　　F. M. G. M.

Preparation of Condensation Products of the Anthracene Series Containing Sulphur. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 251115).—When negatively substituted anthraquinones which in addition contain one or more auxochrome groups are condensed with arylmercaptols they yield compounds which can be employed as pigments, or for the preparation of dyes.

The *compound* obtained when an alcoholic solution of 4-chloro-1-hydroxy-2-methylanthraquinone (54 parts) containing 13 parts of potassium hydroxide is heated at 100° with p-tolyl mercaptan (25 parts) is a crystalline, violet powder. The following *compounds* obtained in a similar manner are described in the original; from p-tolyl mercaptan with (1) 4-chloro-1-amino-2-methylanthraquinone a glistening, bronze, crystalline powder; (2) with 4-bromo-1-methylaminoanthraquinone, glistening, violet needles; (3) with 1-chloroaminoanthraquinone an orange, crystalline powder; whilst 2-bromo-1-amino-4-hydroxyanthraquinone furnishes 1-*amino-4-hydroxyanthraquinone* 2-p-*tolyl thioether*, violet-brown bronze needles, and 2 : 3-dichloro-1 : 4-diaminoanthraquinone yields 1 : 4-*diaminoanthraquinone* 2 : 3-*dithio*-p-*tolyl ether*, blue needles.　　　F. M. G. M.

Preparation of Anthracene Derivatives. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252530. Compare A., 1907, i, 1067).—An account of the preparation of *compounds* of cœrthionium type by heating the following anthraquinone thio-ethers with concentrated sulphuric acid at 150—160°: αα'-dianthraquinonyl thio-ether; αβ-dianthraquinonyl thioether; 4 : 4'- or 5 : 5'-dibenzoyldi-

amino-1 : 1'-dianthraquinonyl thioether, whilst the condensation of 1 : 5-dichloroanthraquinone (1 mol.) with 2 mols. of anthraquinone-2-mercaptol (compare A., 1907, i, 1067) furnishes 1 : 5-*anthraquinonedimercaptol-di-2'-anthraquinonyl thioether*.   F. M. G. M.

Binuclear Quinones of the Anthraquinone Group. HANS MEYER, RICHARD BONDY, and ALFRED ECKERT (*Monatsh.*, 1912, 33, 1447—1468).—The supposed oxidation of dihydrodianthrone by amyl nitrite (Padova, A., 1909, i, 167, 655) to dianthrone is apparently a mistake, as the product is a mixture of anthraquinone with unchanged dihydrodianthrone. *Dianthrone*,

$$CO{<}^{C_6H_4}_{C_6H_4}{>}C{=}C{<}^{C_6H_4}_{C_6H_4}{>}CO,$$
can, however, be easily obtained by the oxidation of dianthranol in alkaline solution with potassium persulphate or hydrogen peroxide; the product, a crystalline powder, is preceded by an intermediate labile green *substance*. If a solution of dianthrone in acetic acid is exposed to sunlight or to the rays from a mercury lamp or an electric arc, it deposits yellow needles of *meso*-naphthadianthrone,

$$CO{<}^{C_6H_3}_{C_6H_3}{>}C{=}C{<}^{C_6H_3}_{C_6H_3}{>}CO$$
(compare Scholl, Mansfield, and Potschiwauscheg, A., 1910, i, 494); the different properties of the substance described earlier are shown to be due to impurity, as the purified substances give practically identical absorption spectra. The substance gives an orange vat, it dissolves in sulphuric acid to a red fluorescent solution, and is oxidised by chromic acid to anthraquinone. The hydrogen liberated during the above conversion of dianthrone into *meso*-naphthadianthrone is probably largely oxidised by oxygen dissolved in the solvent; also, if an atmosphere of carbon dioxide is used, it is observed that some carbon monoxide is formed; only 95% of the original substance is obtained as *meso*-naphthadianthrone, whilst the solvent is found to contain afterwards about 2% of a volatile *hydrocarbon*, leaflets, m. p. 62—63°, possibly hexahydroanthracene, and also a little anthraquinone.

When anthraquinone is submitted in acetic acid to the action of nascent hydrogen (tin and hydrochloric acid) in intense light, the usual products, anthranol and dianthryl, are accompanied by a considerable quantity of dihydroanthracene.

By stopping the action of light on dianthrone at an early stage, dianthranol is found to be present, and is presumably the primary product from which the other substances above are subsequently formed; this idea is supported by the plentiful formation of diacetyldianthranol when a hot solution of dianthrone in acetic anhydride is exposed to light. Diacetyldianthranol in boiling solution when exposed to light for a considerable time is converted largely into a crystalline *substance*, m. p. circa 300°, and a little *meso*-naphthadianthrone.

Helianthrone (Scholl and Mansfield, *loc. cit.*), dissolved in acetic acid and exposed to light, deposits rhombic leaflets of a substance which on crystallisation from nitrobenzene separates in the characteristic needles of *meso*-naphthadianthrone; the identity of

the product was proved by its absorption spectrum. The yield was over 90%, and was accompanied by a brown, amorphous substance possessing the properties of a hydro-derivative of helianthrone.

<div align="right">D. F. T.</div>

Preparation of Borneol and *iso*Borneol Esters. FARBEN-FABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252158).—*Borneyl cinnamate*, b. p. 215°/10 mm., when treated with bromine (in carbon tetrachloride solution) yields *borneyl dibromo-β-phenylpropionate*, colourless, glistening crystals, m. p. 73°; this ester can also be prepared by the action of dibromo-β-phenylcinnamoyl chloride on borneol in the presence of pyridine; the corresponding iso*borneyl* ester forms colourless, glistening leaflets, m. p. 69°.

When *borneyl phenylpropiolate*, b. p. 230—235°/19 mm., is treated with bromine it furnishes *borneyl bromocinnamate*, colourless crystals, m. p. 76°, which is also procurable from borneol and bromocinnamoyl chloride.

Borneyl o-*chlorocinnamate*, colourless crystals, m. p. 102—108° (probably a mixture of two isomerides), on bromination yields *borneyl* o-*chloro-aβ-dibromophenylpropionate*, colourless prisms, m. p 91°.

aβ-Dibromo-m-methoxy-β-phenylpropionyl chloride, m. p. 189°, yields a *borneyl* ester, m. p. 63—64°; *borneyl dibromocinnamate* has m. p. 65°, and *borneyl aβ-dibromo β-p-tolylpropionate*, m. p. 90—91°.

These esters are of therapeutic value.

<div align="right">F. M. G. M.</div>

Preparation of Odourless or Faintly Odorous Esters from Valeric Acid and Therapeutically Powerful Alcohols. J. D. RIEDEL (D.R.-P. 252157).—iso*Valerylglycylborneyl* ester, a viscous liquid, b. p. 181°/12 mm., D^{20} 1·027, is prepared by stirring together borneyl chloroacetate and sodium valerate until the separation of sodium chloride is complete; the corresponding iso*borneyl* ester has b. p. 182—183°/12 mm. and D^{15} 1·0318, whilst the iso*valerylglycyl-menthyl* ester has b. p. 197°/19 mm. and D^{16} 0·986.

<div align="right">F. M. G. M.</div>

Δ^4-Menthen-3 one. OTTO WALLACH, RUD. MULLER, and FR. HENJES (*Chem. Zentr.*, 1912, [ii], 922—923 ; from *Nachr. K. Ges. Wiss. Gott.*, 1912, 431—436).—In order to confirm the description and constitution already assigned to Δ^4-menthen-3-one (A., 1908, i, 813), the authors have prepared it from (*a*) Δ^4-menthene, made from 1 : 4-*cyclo*hexanone, and (*b*) *d*-menthene, obtained from menthol, and find that the characters of these two preparations are the same as those already given. The active specimen had $[a]_D^{18}$ - 67·46° in methyl alcohol. The low boiling point of the ketone is probably due to the position of the *iso*propyl side-chain between a :CO group and an ethylenic linking. The latter probably renders reactive the hydrogen atom in position 6, whilst the :CO group confers reactivity on the neighbouring H-atom (position 2), and this joint action explains the formation of a dibenzylidene derivative from this ketone. No thymol is produced on oxidation with ferric chloride in acetic acid.

<div align="right">T. A. H.</div>

Hydrogenation with Platinum Metals as Catalyst. VI. ALADAR SKITA (*Ber.*, 1912, 45, 3312—3318. Compare A., 1911, i, 1017).—Azobenzene in alcoholic solution is readily reduced by

hydrogen under a pressure of two atmospheres in the presence of colloidal palladium with gum arabic as the protecting colloid. The reduction to hydrazobenzene takes place rapidly, whereas the reduction of the hydrazobenzene to aniline proceeds comparatively slowly.

[With W. A. MEYER and JULIUS VON BERGEN.]—Under conditions similar to those used with azobenzene, a-ionone is reduced to *dihydro-a-ionone*, $C_{13}H_{22}O$, which is a liquid, b. p. 121—122°/14 mm., possessing a slight odour of cedar wood, but the characteristic odour of the a-ionone has disappeared. Similarly, β-ionone gives *dihydro-β-ionone*, b. p. 126—129°/12 mm., possessing properties resembling those of the a-compound. Both the dihydro-compounds on further reduction give the same *tetrahydroionone*, $C_{13}H_{24}O$, b. p. 126—127°/13 mm., showing that it is the ethylene linking in the side-chain which is first reduced.

Tiemann (A., 1898, i, 376) has expressed the opinion that ionone acts as a perfume because of the $a\beta$-ethylene linking in the side-chain. If this is so, a dihydroionone which has been hydrogenised in the nucleus, and still contains an $a\beta$-ethylene linking in the side-chain should still be a perfume. To prepare such a compound, dihydro*cyclo*citral was acetylated in tartaric acid solution by a method similar to that used in preparing ψ-ionone from citral and acetone. The *dihydroionone*, $C_{13}H_{22}O$, thus obtained was a pale yellow liquid, b. p. 124—125°/14 mm., and having an odour similar to that of ionone. Since only the latter compound possesses the character of a perfume, the authors propose that the name dihydroionone should be retained for it, whilst the dihydro-compounds obtained from the a- and β-ionones should be termed $1:1:3$-trimethyl-Δ^3- and $1:1:3$-trimethyl-Δ^2-*cyclo*hexenylethyl methyl ketones respectively.

ψ-Ionone when hydrogenised gives *tetrahydro-ψ-ionone*,

$$CMe_2{:}CH{\cdot}[CH_2]_3{\cdot}CHMe{\cdot}[CH_2]_2{\cdot}COMe,$$
b. p. 126—127°/14 mm

In the unsaturated aldehydes and ketones hitherto examined, with the exception of mesityl oxide (A., 1910, i, 71) and phorone (A., 1909, i, 479), the hydrogenation does not affect the carbonyl group. Acraldehyde also forms an exception, giving allyl alcohol together with propaldehyde.

[With FRIEDRICH NORD.]—The following alkaloids have been hydrogenised by method similar to that used with quinone and cinchonine (A., 1911, i, 1017), the protecting colloid not being used. Quinidine gives *dihydroquinidine*, $C_{20}H_{26}O_2N_2,H_2O$, m. p. 165°, $[a]_D^{20}$ +265·3°; the *methiodide*, $C_{22}H_{27}O_2N_2I$, forms slender, light yellow needles, m. p. 224—225°, and the *phosphate*, $C_{20}H_{29}O_6N_2P$, decomposes at 212°. Cinchonidine gives *dihydrocinchonidine*, $C_{19}H_{24}ON_2$, m. p. 229°, $[a]_D^{20}$ −97·5°, the *methiodide*, $C_{20}H_{27}ON_2I$, and *phosphate*, $C_{19}H_{27}O_3N_2P$, of which have the m. p.'s 248° and 113° respectively. The dihydroquinidine is identical with the naturally-occurring hydroconquinine, and the dihydrocinchonidine with hydrocinchonidine.   T. S. P.

[Glycuronic Acids Produced by the Coupling of Alicyclic Compounds in the Organism.] JUHO HÄMÄLÄINEN (*Skand. Arch. Physiol.*, 1912, 27, 141—226).—See this vol., i, 133.

The Simultaneous Action of Catalysts. VLADIMIR N. IPATIEV (*Ber.*, 1912, **45**, 3205—3218. Compare A., 1911, i, 31).—[With N. MATOV.]—In order to prepare fenchane from fenchone, the latter was first heated with hydrogen under pressure (110 atmos.) for twenty hours at 240°, whereby fenchenol, b. p. 196°/752 mm. and D^{20} 0·9554, was obtained. Attempts to prepare fenchene, which could then be hydrogenised to fenchane, from fenchenol by the fission of water under the catalytic action of alumina at temperatures varying from 210° to 255° gave only very small yields, and the use of the bromo-compound gave no better results. When, however, fenchenol was heated at 215° for twelve to fourteen hours with hydrogen under a pressure of 110 atmos., in the presence of a mixture of nickel oxide and alumina as catalysts, fenchane was obtained directly; $[a]_D$ − 19 83°, D^{17} 0·8766, D^{20} 0·8733, n^{17} 1·45409.

The hydrogenisation of commercial camphene (m. p. 48·5°, b. p. 160—165°/761 mm.) in the presence of nickel oxide at 240° gives *iso*camphane, m. p. 53·5—57°, b. p. 162·5—163·5°/758 mm., D^{19} 0·8457.

Attempts to prepare camphene by the dehydration of borneol in the presence of alumina at 350—360° gave only small yields of a liquid camphene, together with large quantities of oxidation products, the reaction being a very slow one. When, however, borneol (m. p. 208—210°, b. p. 215°, $[a]_D$ + 30·21°) is hydrogenised at 215—220° under 110 atmos. pressure in the presence of a mixture of nickel oxide and alumina, *iso*camphane is obtained, m. p. 63—64·5°, b. p. 164°/757 mm., D^{70} 0·84157, $[a]_D$ − 8·50°. Under similar conditions, *iso*borneol (m. p. 209°, b. p. 211°, $[a]_D$ − 1·82°) also gives rise to *iso*camphane, m. p. 62·5—64°, b. p. 164—164·5°/756·1 mm., D^{70} 0·84293, $[a]_D$ − 2·81°. When heated with alumina alone at 350—360°, *iso*borneol yields small quantities of crystalline camphene, together with considerable quantities of condensation products.

The transformation of cyclic ketones into the saturated hydro-carbons by the combined action of reduction and dehydration catalysts takes place readily, at much lower temperatures than in the reduction of the alcohols. In the presence of a mixture of nickel oxide and alumina at 200°, carvomenthone is readily reduced to menthane by hydrogen under pressure. Similarly, camphor (m. p. 174·5—176°, b. p. 203·5°/743·2 mm., $[a]_D$ + 33·20°) at 200° gives *iso*camphane (m. p. 64·5—65·5, b. p. 164—165°/757 mm., D^{70} 0·8462, $[a]_D$ − 3·95°). Comparison of the physical properties of the various *iso*camphanes prepared from camphene, borneol, *iso*borneol, and camphor shows that they are very similar to each other.

When a mixture of alumina and copper oxide is used instead of alumina and nickel oxide as catalyst, terpene alcohols give rise to unsaturated hydrocarbons. The temperature of dehydration is much lower, being 220° instead of 360°, and in consequence of this lower temperature there is no hydrogenisation of the double linking in the presence of the copper oxide. Under such conditions borneol at 200—220° and a hydrogen pressure of 50 atmos., gives a mixture of solid and liquid camphene, the former having m. p. 60—62·5°, b. p. 156—159°/763 mm., D^{70} 0·85075, and the latter b. p. 155—160°/

763 mm., D^{16} 0·8688, $[a]_D$ 1·61°, n^{16} 1·45819. This liquid camphene yields a chloride, m. p. 140°, and when hydrogenised in the presence of nickel oxide gives liquid *isocamphane*, b. p. 160—165°, D^{18} 0·85204, n^{18} 1·45009.

Under the same conditions as with *corneol*, *isoborneol* gives rise only to a solid camphene, m. p. 53·5°, b. p. 162—167°/766 mm., D^{70} 0·85092, n^{60} 1·44244.

[With O. ROUTALA.]—At 240°, in the presence of a mixture of alumina and copper oxide and under a hydrogen pressure of 20 atmos., 1-methyl*cyclo*hexan-2-ol yields methyl-Δ^1-*cyclo*hexene (compare A., 1911, i, 25), b. p. 107·5—108·5°/759·5 mm., D_4^{18} 0·8063, n^{18} 1·44094. The *nitrosochloride*, C_7H_{12}·NOCl, m. p. 102°, is very unstable, decomposing in a desiccator with the formation of the *oxime*, C_7H_{10}:NOH. The *nitrosate*, $C_7H_{12}O_4N_2$, has m. p. 115°. By the addition of hydrogen bromide in acetic acid solution, 1-*bromomethyl*cyclo*hexane* is obtained as a colourless liquid, b. p. 156—160°, D^{18} 1·2544, n^{18} 1·48168. The action of silver oxide on this compound gives rise to small quantities only of the alcohol, the methyl*cyclo*hexene being regenerated for the most part. With silver acetate, however, the *acetic* ester, $C_9H_{16}O_2$, is readily obtained, b. p. 182—187°, D^{18} 0·9536, n^{18} 1·43862, which, on saponification with alcoholic alkali gives 1-*methyl*cyclo*hexan-1-ol*, $C_7H_{14}O$, b. p. 159—164°/759 mm., D^{18} 0·9417, n^{18} 1·45179.

Attempts to prepare the bromide from 1-methyl*cyclo*hexan-2-ol by the action of phosphorus tribromide were unsuccessful, owing to the ready fission of hydrogen bromide.

To explain the greater catalytic effect of the combined catalysts, it is assumed that a labile complex, for example, NiO,Al_2O_3, is formed as an intermediate product, and then decomposes, giving the components in the nascent state. The combined action of the catalysts is called "hydrolytic reduction." T. S. P.

Constituents of Ethereal Oils. The Sesquiterpene Selinene and its Derivatives. FRIEDRICH W. SEMMLER and FELIX RISSE (*Ber.*, 1912, 45, 3301—3307. Compare Schimmel, A., 1910, i, 328).— Selinene, $C_{15}H_{24}$, the sesquiterpene from celery seed oil, which has b. p. 128—132°/11 mm., D^{20} 0·9190, n_D 1·5092, $[a]_D+61°36'$, is shown to be a bicyclic doubly unsaturated hydrocarbon. On reduction with hydrogen in presence of finely divided platinum, or of the dihydrochloride with sodium and alcohol, *tetrahydroselinene*, $C_{15}H_{28}$, is obtained, b. p. 126—128°/10·5 mm., D^{20} 0·8881, n_D 1·48259, $[a]_D+7°$.

When selinene dihydrochloride is treated with calcium hydroxide, one halogen atom is eliminated as hydrogen chloride, and the other replaced by hydroxyl, the alcohol *selinenol*, $C_{15}H_{26}O$, being obtained; it has b. p. 155—163°/19 mm., D^{20} 0·9627, n_D 1·50895, $[a]_D+52°36'$. On reduction, *dihydroselinenol*, crystallising in colourless needles, m. p. 86—87°, is obtained. The preparation of this compound is the best method of detecting selinene. E. F. A.

Extraction of Coffee Oil. VIKTOR GRAFE (*Monatsh.*, 1912, 33, 1389—1406. Compare Erdmann, A., 1902, i, 551).—From a comparison with ordinary coffee beans and beans which have been previously deprived of caffeine, it is found that the latter give less coffee oil, the

shortage being especially in the furfuryl alcohol of the mixture. Beans freed from skin and wax gave practically the same results as ordinary beans, so that the parent substance of the coffee oil must have been still present. It is believed that the treatment preceding the extraction of the caffeine diminishes the content of fibrous matter, and causes partial decomposition of the chlorogenic and coffalic acids; these acids are regarded as the source of the valeric acid in coffee oil, whilst the fibrous matter is the origin of the furfuryl alcohol.

D. F. T.

Desulphuration of Vulcanised Rubber. PAUL ALEXANDER (*Chem. Zeit.*, 1912, 36, 1289—1291, 1340—1342, 1358—1359).—The author has stated previously (*ibid.*, 1910, 34, 789) that it is impossible to remove the combined sulphur from vulcanised rubber without destroying the rubber substance. The work of Hinrichsen and Kindscher (A., 1912, i, 706) having placed this conclusion in doubt, the author has repeated and extended this work.

Para rubber was vulcanised by mixing it with varying quantities (5 to 20 parts) of sulphur and heating at 143° under 4 atmospheres pressure. The products (A—E) were then treated in benzene solution with (1) alcoholic sodium hydroxide; (2) alcoholic sodium hydroxide in presence of zinc, magnesium or calcium, and the materials (A_1A_2, B_1B_2, C_1C_2, etc.) thus obtained examined in comparison with the original products. The results are too numerous to quote, but the most interesting are the "vulcanisation-coefficients" arrived at in three different ways: (1) calculated from the total sulphur, less the sum of the sulphur in the ash and that in the "matter soluble in acetone"; (2) calculated from the sulphur in the "matter insoluble in acetone," less the sulphur in the ash, and (3) the sulphur in the nitrosite prepared from the product under examination. From the whole of his results the author draws the conclusion that the last method gives the true vulcanisation-coefficient, that is, the amount of sulphur which combines with 100 parts of pure rubber. The following general conclusions are drawn: The methods described, which are those of Hinrichsen and Kindscher, do not remove combined sulphur from vulcanised rubber, but actually increase the amount in combination when insufficient sodium hydroxide to combine with all the free sulphur is used. The metals used exert no action in this direction. The whole of the free sulphur is not removed from vulcanised rubber by extraction with acetone, probably because part of it at the temperature of vulcanisation is converted into a modified form, which is insoluble in acetone, but dissolves in alcoholic sodium hydroxide. The products (A_1A_2, etc.) referred to above contain "depolymerised rubber," which is soluble in acetone; this material is produced by the heat applied, and not by the action of the alkali hydroxide or the metals or solvents used. The rest of the paper is polemical in favour of Loewen (A., 1912, ii, 914, 915) against Hinrichsen and Kindscher (A., 1912, i, 1007).

T. A. H.

Resin of Pinus Halepensis. L. REUTTER (*J. Pharm. Chim.*, 1912, [vi], 6, 497—500).—This resin has m. p. 83—85°, acid number

180·75—182·74, saponification number 196·5—199·3, ester number 15·7—16·5, and gives colour reactions similar to those of cholesterol. The portion soluble in ether yields to aqueous ammonium carbonate, *helepinic acid*, $C_{21}H_{40}O_4$, m. p. 73·5—74·5°, and subsequently to aqueous sodium carbonate : (1) *helepinolic acid*, $C_{40}H_{56}O_5$, m. p. 144·2—145·5°, which is crystalline and yields a *silver* salt ; (2) *a-helepinolic acid* $C_{84}H_{50}O_4$, m. p. 80 5—81·5°, which is soluble in alcohol, but yields a lead salt insoluble in that solvent ; (3) *β-helepinolic acid*, $C_{18}H_{28}O_4$, m. p.·80·5—82°, which is soluble in alcohol and yields a *lead* salt also soluble in alcohol, and (4) *heleponic acid*, $C_{18}H_{28}O_2$, m. ,p. 156—157°, separating from methyl alcohol in crystals. The resin also contains 14·4% of volatile oil (compare Tschirch and Schulz, A., 1907, i, 544).

T. A. H.

The Resinous Exudation of Pinus Pinea. L. REUTTER (*J. Pharm. Chim*, 1912, [vi], 6, 494—497).—The portion of the oleo-resin soluble in ether yielded on extraction with (1) aqueous ammonium carbonate, *pineic acid*, $C_7H_{14}O_4$, m. p. 99—99·5°, and (2) aqueous sodium carbonate, *pineolic acid*, $C_{18}H_{28}O_8$, m. p. 86°, and a very small amount of a substance giving a precipitate with alcoholic lead acetate. The portion insoluble in ether on steam distillation yielded *pinearesen*, $C_9H_{18}O_4$, m. p. 85°, and a volatile oil, which had an odour recalling that of turpentine, and when kept deposited colourless crystals, m. p. 204°, with an odour similar to that of borneol.

T. A. H.

Chemical Composition of Dulcamara. GEORGES MASSON (*Chem. Zentr.*, 1912, i, 366—367 ; from *Bull. Sci. Pharm.*, 1912, 19, 283—289. Compare Desfosses, *Jahresb.*, 1820, 2, 114 ; Davis, A., 1902, ii, 686).—The aërial portion of dulcamara is free from solanine, but contains in addition to proteins, gums, and reducing sugars, dulcamaretic acid, dulcamaric acid, and solacein (1%). The two acids are both soluble in alcohol, but the first only is soluble in ether, and they can be separated by the use of this solvent.

Dulcamaric acid is a glucosidic saponoid ; it forms a greenish-brown powder, m. p. 190° (decomp.), and yields brown, amorphous salts with alkalis. On hydrolysis with 7% sulphuric acid in alcohol it furnishes (1) *dulcamarigenic acid*, m. p. 160°, and (2) a reducing sugar, which gives a *phenylosazone*, m. p. 196—197°, crystallising from boiling water in slender needles.

Dulcamaretic acid, m. p. 90—92°, is a non-glucosidic saponoid ; it forms a green buttery mass, giving green, amorphous alkali salts. It could not be hydrolysed.

Solacein, m. p. 236—237°, is a nitrogenous glucoside ; it forms a colourless, amorphous mass, soluble in alcohol, but insoluble in ether or water, and reduces auric chloride or silver nitrate on warming, but not Fehling's solution. It yields a yellow *platinichloride*, a stable *sulphate*, and a gelatinous *hydrochloride*. On hydrolysis by acids it furnishes solanidine, m. p. 190°, and a sugar from which a *phenylosazone*, m. p. 171—172°, crystallising in needles from methyl alcohol, was prepared.

Dulcamarin is regarded as an alkali compound of the two acid saponoids.   T. A. H.

Picrotoxin. FRANCESCO ANGELICO (*Gazzetta*, 1912, **42**, ii, 540—545. Compare A., 1911, i, 1003).—When the ketone, $C_{14}H_{16}O_3$ (obtained by the action of hydriodic acid and red phosphorus on picrotoxin, as already described), is heated with concentrated alcoholic potassium hydroxide, a new *compound*, $C_{12}H_{14}O_2$ is obtained in good yield. This substance crystallises in large, colourless needles, m. p. 81°, b. p. 290°; it is volatile with steam and has an odour of celery like the phthalides. It is stable towards oxidisers and reducers, but when heated at 260—280° with three times its weight of powdered potassium hydroxide, it yields acetone and 2 : 3-dimethylbenzoic acid, the barium salt of which gives o-xylene when distilled with barium oxide. When the phthalide, $C_{12}H_{14}O_2$, is oxidised with nitric acid, it yields an *acid*, $C_{12}H_{14}O_4$, of the probable constitution II, whilst when it is oxidised with alkaline potassium permanganate it yields an *acid*, $C_{12}H_{10}O_6,H_2O$, of the probable formula III. This acid gives a fluorescein with resorcinol, and when fused with potassium hydroxide yields acetone and 1 : 2 : 3-benzenetricarboxylic acid. The acid, $C_{12}H_{10}O_6,H_2O$, loses H_2O at about 130°, and gives potassium and silver salts. In view of these reactions, the compound, $C_{12}H_{14}O_2$, probably has the structure indicated in formula I.

(I.)   (II.)   (III.)
The phthalide has been obtained by other means (but not identified) by Sielisch (A., 1912, i, 886).

The ketone, $C_{14}H_{16}O_3$, from which the phthalide is obtained, also loses acetone when fused with potassium hydroxide, and probably contains the keto-methylenic grouping, since the action on it of amyl nitrite and sodium ethoxide gives an oximino-compound, m. p. 215° (decomp.), which is converted by hydroxylamine into a dioxime. In consequence of these results and of those formerly published, the author regards picrotoxinine and picrotin, not as hydronaphthalene derivatives, but as hydrobenzene derivatives, related to *cyclo*hexene and *cyclo*hexane respectively. He suggests, therefore, the following provisional formulæ for the two substances :
R. V. S.

Picrotinic Acids. PAUL HORRMANN (*Ber.*, 1912, **45**, 3434—3437). —Angelico has given the formula $C_{15}H_{18}O_8$ to α-picrotinic acid and $C_{17}H_{24}O_8$ to its ethyl ester (A., 1910, i, 404). One or other of these formulæ must be wrong. The author shows that α-picrotinic acid has the formula $C_{15}H_{20}O_8$, decomp. 258°, and is identical with Horrmann and Seydel's δ-picrotinic acid (A., 1912, i, 1008). It is not an oxidation product of picrotin, but is produced merely by the addition of water.   C. S.

Tannin. KARL FEIST (*Arch. Pharm.*, 1912, **250**, 668—683).—The author has stated previously that "Turkish" galls contain glucogallic acid and a tannin, which yields dextrose on hydrolysis by acids (A., 1912, i, 566, 888). These two substances are now described.

"Turkish" galls were extracted in turn with chloroform, benzene, and dry ether. The chloroform extract contained chlorophyll, *cyclo*gallipharic acid, and gallic acid. Benzene removed nothing of importance. The ether extract consisted of glucogallic acid and a little tannin. The former was isolated by dissolving the dry extract in acetone, allowing the latter to evaporate, and pouring off the mother liquor as long as amorphous matter separated. Eventually *glucogallic acid* separated in rosettes of greyish needles. It can be prepared in like manner from commercial tannin derived from "Turkish" galls. Glucogallic acid, m. p. 233° (decomp. anhydrous), $[\alpha]_D^{17} + 10\cdot6°$ in acetone, contains when air-dry about 12% of water, and has a molecular weight, when dry, of about 318 as determined by titration (assuming 1 CO_2H group) or by the b. p. method. On hydrolysis by boiling with *N*-sulphuric acid it yields dextrose and gallic acid. It reduces Fehling's solution on boiling, and yields a semi-crystalline *methyl* derivative, m. p. 79°, which, unlike the acid itself, gives no coloration with ferric chloride, and does not reduce Fehling's solution. Glucogallic acid is not decomposed by emulsin, so that it is probably an α-glucoside; it probably does not contain a free ·CHO group.

The partly exhausted galls were next extracted with hot acetone. The *tannin* (designated "Turkish" tannin to distinguish it from that obtained from "Chinese" galls) had $[\alpha]_D + 28\cdot6°$ to $+ 31°$, and molecular weight 615—746 (b. p. method). On treatment with diazomethane in ether, part of it dissolved and was methylated (compare Herzig and Tscherne, A., 1905, i, 354). On hydrolysis the tannin yields dextrose and gallic acid; no glucogallic acid could be obtained as an intermediate product in this hydrolysis (compare Fischer and Freudenberg, A., 1912, i, 471, 887).

The tannin of "Chinese" galls (A., 1912, i, 888) has a molecular weight 899—1045, and is partly methylated on treatment with diazomethane in ether.   T. A. H.

Action of Nitric Acid and Silver Nitrate on Tannin. ROGER DOURIS and A. WIRTH (*Chem. Zentr.*, 1912, ii, 1360; from *Bull. Sci. Pharmacol.*, 1912, **19**, 403—407).—When a solution of tannin is boiled with nitric acid and silver nitrate, silver cyanide is precipitated, the maximum yield occurring with the proportions 2 grams of silver nitrate, 10 c.c. of nitric acid (40° Bé.), and 2 grams of tannin, made up

to 100 c.c. with water. With a mixture of twice this concentration, a very violent reaction results in the formation of oxalic acid. Gallic acid has the same effect, but with pyrogallol or quinol the product is masked by the large amount of reduced silver which is also formed.

<div align="right">J. C. W.</div>

Ratanhine. GUIDO GOLDSCHMIEDT (*Monatsh.*, 1912, 33, 1379—1388). —Ratanhine occurs only exceptionally in ratanhin extract (compare Kreitmair, A., 1874, 1038).

A specimen which came into the author's possession had the composition $C_{10}H_{18}O_8N$, m. p. 252° (decomp.); *hydrochloride*, monoclinic crystals $[a:b:c = 1\cdot0283 : 1 : 0\cdot5111,\ \beta = 103\cdot77°]$; *copper* salt, deep violet prisms; *methyl* ester, m. p. 116—117°, monoclinic prisms $[a:b:c = 0\cdot8096 : 1 : 0\cdot8107,\ \beta = 116\cdot32°]$. On fusion with potassium hydroxide, ratanhine yielded *p*-hydroxybenzoic acid, whilst decomposition by heat gave a *base*; *hydrochloride*, $C_{10}H_{13}ON,HCl$, colourless prisms.

<div align="right">D. F. T.</div>

Degradation of Bilirubin and Bilirubic Acid. HANS FISCHER and HEINRICH ROSE (*Ber.*, 1912, 45, 3274—3280).—Previously only traces of bases have been obtained on reduction of bilirubin. On boiling for fourteen to sixteen hours with acetic acid and hydrogen iodide, cryptopyrrole, $NH{<}^{CH=CMe}_{CMe:CEt}$, is readily obtained. It is left undecided whether hæmopyrrole and phyllopyrrole are also present. The second degradation product, the isomeric phonopyrrolecarboxylic acid, was isolated in relatively considerable quantity. It is readily esterified by means of methyl alcohol and dry hydrogen chloride, a method which is also applicable to phonopyrrolecarboxylic acid. This ester forms a dark brownish-red picrate, whereas the picrate of the isomeric ester is a normal yellow colour.

Bilirubic acid when reduced in a similar manner yields cryptopyrrole in small quantity together with a large proportion of the isomeric phonopyrrolecarboxylic acid; a considerable amount of the bilirubic acid remains unattacked. The results are interpreted as in favour of the formula:

$$\begin{matrix}CEt\cdot CMe\\CMe\cdot NH\end{matrix}{>}C\cdot O\cdot C{<}\begin{matrix}CMe\cdot C\cdot CH_2\cdot CH_2\cdot CO_2H,\\NH-CMe\end{matrix}$$

for bilirubic acid.

Methyl phonopyrrolecarboxylate crystallises in colourless, flat needles, m. p. 57—58°. The *picrate* forms reddish-brown needles with a marked lustre, m. p. 121—122°. The *picrate* of the isomeric *methyl phonopyrrolecarboxylate* crystallises in slender, yellow, concentrically-grouped needles, m. p. 107—108°. The free *ester* obtained from the picrate forms crystals, m. p. 47—48°.

<div align="right">E. F. A.</div>

Bile Pigments. IV. HANS FISCHER and HEINRICH ROSE (*Zeitsch. physiol. Chem.*, 1912, 82, 391—405).—In part already abstracted (preceding abstract). On oxidation of bilirubin after reduction with sodium amalgam, methyl ethylmaleinimide and the oxime of phonopyrrole

carboxylic acid are obtained. This observation makes the existence of a third pyrrole complex in bilirubin probable.

Methylethylmaleinimide is also obtained on oxidation of bilirubic acid together probably with the oxime of phonopyrrolecarboxylic acid.

E. F. A.

Transformation of an Alcohol into a Sulphide or a Peroxide by Hydrogen Sulphide or Hydrogen Peroxide. ROBERT FOSSE (*Compt. rend.*, 1912, 155, 1019—1020).—Xanthhydrol reacts with hydrogen sulphide or hydrogen peroxide as does a basic hydroxide, giving rise respectively to a sulphide and a peroxide.

On passing a stream of hydrogen sulphide into a solution of xanthhydrol in acetic acid a white, microcrystalline deposit of *xanthyl sulphide*, $\left(O{<}{C_6H_4 \atop C_6H_4}{>}CH\right)_2S$, is obtained, which is decomposed by hydrochloric acid, giving hydrogen sulphide and unstable xanthyl chloride. *Xanthyl peroxide*, $\left(O{<}{C_6H_4 \atop C_6H_4}{>}CH\right)_2O_2$, is similarly prepared by the addition of hydrogen peroxide to the acetic acid solution of xanthhydrol. On boiling it with fuming hydrochloric acid, chlorine is evolved and a pyrryl salt is produced. The peroxide gives an orange-yellow solution in a mixture of acetic and hydrochloric acids, which with chlorides or bromides of gold or uranium yields double xanthyl metallic chlorides or bromides.

W. G.

Triphenylmethyl. XXI. Quinocarbonium Salts of the Hydroxyxanthenols. MOSES GOMBERG and C. J. WEST (*J. Amer. Chem. Soc.*, 1912, 34, 1529—1569).—In an earlier paper (A., 1911, i, 737) it was stated that hydroxy- and methoxy-xanthenols yield colourless carbinyl chlorides which are capable of uniting with a metal haloid, a halogen, or hydrogen haloid to form coloured quinocarbonium salts (compare Gomberg and Cone, A., 1910, i, 55, 869). A study has now been made of the salts of *p*-, 1-, 2-, 3-, and -4-hydroxy- and -methoxy-phenylxanthenol and of 3:6-dihydroxyphenylxanthenol.

It has been found that the hydroxy- and methoxy-groups cause a deepening of the colour of the quinonoid derivatives from the yellow of phenylxanthenol to deep red except in the case of the 3-derivatives which are yellow. The presence of these groups increases the stability of the quinonoid compounds, but diminishes that of the benzenoid salts; it also increases the reactivity of the xanthones. The influence of acetoxy- and benzoxy-groups diminishes the tendency of the compounds to tautomerise into the quinonoid form. The constitution of the compounds is discussed.

I. p-*Hydroxyphenylxanthenol Compounds.*—p-*Anisylxanthenol*,

$$OMe{\cdot}C_6H_4{\cdot}C(OH){<}{C_6H_4 \atop C_6H_4}{>}O,$$
m. p. 120—121°, prepared by adding xanthone to the product of the action of magnesium on *p*-anisyl iodide, separates from benzene in white, prismatic crystals, containing $\frac{1}{2}C_6H_6$, and from ether or acetone in large, monoclinic prisms. p-*Anisylquinoxanthenol chloride*

hydrochloride, $\text{HCl,CHCl·CH:C} \overbrace{\hspace{2.5cm}}^{} \text{O} \atop \text{CH=CH-C:C(C}_6\text{H}_4\text{·OMe)}} \Big\rangle \text{C}_6\text{H}_4$, m. p. 110—115°

(decomp.), prepared by saturating a benzene solution of the xanthenol, to which a little acetyl chloride has been added, with hydrogen chloride, forms dark red crystals. If this salt is suspended in benzene or light petroleum and a current of air passed through the mixture, the hydrogen chloride is removed, and p-*anisylxanthenol chloride,* $\text{OMe·C}_6\text{H}_4\text{·CCl} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{O}$, m. p. 95—96°, is produced, which forms colourless crystals. When a solution of the chloride in benzene is shaken with molecular silver, an unsaturated compound, analogous to triphenylmethyl, is formed, which on exposure to the air is converted into the *peroxide,* $\left[\text{O} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{C(C}_6\text{H}_4\text{·OMe)} \right]_2 \text{O}_2$, m. p. 214° (decomp.), obtained as a white, crystalline powder. The following additive compounds of the chloride are described : *ferrichloride,* m. p. 198—199°; *zincichloride,* m. p. 240—241°; *mercurichloride,* m. p. 185—186°; *perbromide,* m. p. 159—163° (decomp.); and *periodide.* p-Anisylxanthenol *ethyl ether,*

$$\text{O} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{C(OEt)·C}_6\text{H}_4\text{·OMe,}$$
m. p. 156—157°, and *methyl ether,* m. p. 129—130°, form colourless crystals.

p-*Anisylquinoxanthenol bromide hydrobromide* is a dark brown, crystalline substance. The *bromide,* $\text{OMe·C}_6\text{H}_4\text{·CBr} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{O}$, forms colourless crystals ; its *zincibromide* has m. p. 224—225°; *mercuribromide,* m. p. 192—194°; *perbromide,* m. p. 174—175°, and *periodide,* m. p. 187—189°. p-Methoxyphenylxanthenol *perchlorate,* m. p. 192—193°; hydrogen sulphate, m. p. 117—118°, and *phosphate,* m. p. 124—125°, are described.

p-*Hydroxyphenylxanthenol,* $\text{O} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{C(OH)·C}_6\text{H}_4\text{·OH,}$ m. p. 149—150° (decomp.), prepared from p-anisylxanthenol by Baeyer's method (A., 1910, i, 251), crystallises in rosettes of colourless needles. The *perchlorate* has m. p. 255—256°, and the *hydrogen sulphate,* m. p. 240—245°. p-*Hydroxyphenylquinoxanthenol chloride hydrochloride,* $\text{O} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}> \text{C:C}_6\text{H}_4 <^{\text{OH}}_{\text{Cl,HCl}}$ or

$$\text{O} <^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4\text{(Cl,HCl)}} > \text{C·C}_6\text{H}_4\text{·OH,}$$
m. p. 235—240°, forms dark red, iridescent plates. p-*Hydroxyphenyl-quinoxanthenol chloride,* m. p. 235—245° (decomp.), is obtained as a red powder by heating the hydrochloride in a vacuum at 130°; its *ferrichloride* has m. p. 156—157°; *zincichloride,* m. p. 222—223°; *mercurichloride,* m. p. 215—216°, and *perbromide,* m. p. 230—235°; the *periodide* is purple. p-*Hydroxyphenylquinoxanthenol bromide,* m. p. 258—260° (decomp.), is a red, crystalline powder. When p-hydroxyphenylxanthenol is heated at 110—120° for two hours, it loses a molecule of water and is converted into *xanthylene-*

quinomethane, $O<^{C_6H_4}_{C_6H_4}>C<^{CH:CH}_{CH:CH}>CO$, m. p. 287—288°, which
has a green colour, and is readily hydrolysed by dilute acid or
alcoholic potassium hydroxide with regeneration of *p*-hydroxyphenyl-
xanthenol.   If the quinone is treated with hydrogen chloride,
p-hydroxyphenylquinoxanthenol chloride hydrochloride is produced,
whilst by the action of hydrogen bromide, *p*-hydroxyphenylquino-
xanthenol bromide is obtained. Acetic anhydride converts the quinone
into *p*-acetoxyphenylxanthenol. The quinone unites with 1 mol. of
methyl sulphate to form a red additive compound which yields
p-anisylxanthenol on hydrolysis.   By the action of phosphorus
pentachloride the quinone is converted into *p*-chlorophenylxanthenol
chloride (Gomberg and Cone, A., 1910, i, 57).

p-*Acetoxyphenylxanthenol,* $O<^{C_6H_4}_{C_6H_4}>C(OH)·C_6H_4·OAc$,   m.   p.
145—146°, obtained by the action of acetic anhydride and sodium
acetate on *p*-hydroxyphenylxanthenol, crystallises in long, slender,
colourless needles. p-*Acetoxyphenylquinoxanthenol chloride hydrochloride,*
$O<^{C_6H_4————}_{C_6H_4(Cl,HCl)}>C·C_6H_4·OAc$, m. p. 118—122° (decomp.), forms
light red crystals. p-*Acetoxyphenylxanthenol chloride,*

$$O<^{C_6H_4}_{C_6H_4}>CCl·C_6H_4·OAc,$$
is obtained in colourless crystals; its *ferrichloride* has m. p. 182°;
zincichloride, m. p. 194°; *stannichloride,* m. p. 188°, and *mercuri-
chloride,* m. p. 215°; the *perbromide* has an orange colour. The
peroxide, $\left[O<^{C_6H_4}_{C_6H_4}>C(C_6H_4·OAc)\right]_2O_2$, has m. p. 211—212° (decomp.).

p-*Benzoxyphenylxanthenol,* $O<^{C_6H_4}_{C_6H_4}>C(OH)·C_6H_4·OBz$,   m.   p.
181—182°, forms colourless crystals. p-*Benzoxyphenylquinoxanthenol
chloride hydrochloride,* m. p. 143—145° (decomp.), varies in colour
from yellow to orange-red. p-*Benzoxyphenylxanthenol chloride,* m. p.
175—176°, yields additive *compounds* with ferric chloride, m. p.
204—205°, and with zinc chloride; the *perchlorate* has m. p. 235—236°.
p-*Benzoxyphenylxanthenol peroxide* has m. p. 218—219° (decomp.).

II. 1 - *Hydroxy* - 9 - *phenylxanthenol   Compounds.*—Hydroxy- and
methoxy-xanthones combine much more readily with metal haloids
than xanthone itself. The hydrogen haloid additive compounds are
very unstable, and can only be prepared in absence of water.
1-Methoxyxanthone (Tambor, A., 1910, i, 559) yields the following
compounds: *stannichloride,* m. p. 135—136°; *stannibromide,* m. p.
172—173°; *mercurichloride,* m. p. 183—184°; *mercuribromide,* m. p.
167—168°; *zincichloride* and *zincibromide,* and the *hydrochloride,*
m. p. 110—115°.

1-*Methoxy-9-phenylxanthenol,* $OH·CPh<^{C_6H_4————}_{C_6H_3(OMe)}>O$,   m.   p.
162—163°, prepared by adding 1-methoxyxanthone to a solution of
magnesium phenyl bromide, forms lustrous, colourless needles; its
perchlorate has m. p. 225°. 1-*Methoxy-9-phenylquinoxanthenol chloride*

hydrochloride, $O<^{C_6H_4}_{C_6H_3 \cdot OMe(Cl,HCl)}>CPh$, crystallises in lustrous, purple needles. *1-Methoxy-9-phenylxanthenol chloride,*

$$O<^{C_6H_4}_{C_6H_3(OMe)}>CPhCl,$$
m. p. 160—161°. forms colourless crystals and yields coloured additive compounds with metal haloids. The *peroxide* has m. p. 200—201°.

1-Hydroxy-9-phenylxanthenol, $OH \cdot CPh<^{C_6H_4}_{C_6H_3(OH)}>O$, m. p. 148—150° (decomp.), forms colourless crystals, and yields a dark purple *perchlorate,* m. p. 249—250°. 1-Hydroxy-9-phenylxanthenol chloride could not be isolated, but its *ferrichloride,* m. p. 146—147°, and *stannichloride,* m. p. 185°, were prepared.

III. *2-Hydroxy-9-phenylxanthenol Compounds.*—2-Methoxyxanthone furnishes the following additive compounds: *stannichloride,* m. p. 235—240°; *stannibromide,* m. p. 199—200°; *zincichloride,* m. p. 244—245°; *mercurichloride,* m. p. 200°; *mercuribromide,* m. p. 187—189°; *perchlorate,* m. p. 150—155°. *2-Methoxy-9-phenylquinoxanthenol chloride hydrochloride,* m. p. 140—144° (decomp.), forms bright red crystals. *2-Methoxy-9-phenylxanthenol chloride* has m. p. 198°, and yields a *ferrichloride,* m. p. 123—124°; *zincichloride,* m. p. 197—198°; *mercurichloride; stannichloride,* m. p. 147—149°, and *perbromide.* *2-Methoxy-9-phenylquinoxanthenol bromide hydrobromide* forms deep red crystals and decomposes at 223—224°. *2-Methoxy-9-phenylxanthenol bromide* is colourless, and yields coloured additive compounds with metal haloids; the *perchlorate* and *hydrogen sulphate* have m. p. 193—194° and 110—120° respectively.

2-Hydroxy-9-phenylxanthenol has m. p. 170°. *2-Hydroxy-9-phenylquinoxanthenol chloride hydrochloride,* m. p. about 240°, is obtained as a dark red powder. *2-Hydroxy-9-phenylxanthenol chloride* is colourless, and gives coloured additive compounds with metal haloids. 2-Hydroxy-9-phenylquinoxanthenol bromide (Kropp and Decker, A., 1909, i, 249) yields a *perchlorate,* m. p. about 260°, and *hydrogen sulphate,* m. p. 133—135°.

2-Acetoxy-9-phenylxanthenol, m. p. 151—152°, is a colourless, crystalline substance; the *perchlorate* has m. p. 180—185°. *2-Acetoxy-9-phenylquinoxanthenol chloride hydrochloride,* m. p. 125—129° (decomp.), forms light orange crystals. *2-Acetoxy-9-phenylxanthenol chloride* is colourless and gives coloured additive compounds with metal haloids. The *peroxide,* m. p. 128° (decomp.), forms white crystals.

2-Benzoxy-9-phenylxanthenol, m. p. 205—206°, is colourless; its *perchlorate* has m. p. 210°. *2-Benzoxy-9-phenylquinoxanthenol chloride hydrochloride,* m. p. 147—148°, forms light red crystals. *2-Benzoxy-9-phenylxanthenol chloride,* m. p. 190°, yields coloured additive compounds. The *peroxide* has m. p. 170° (decomp.).

IV. *3-Hydroxy-9-phenylxanthenol Compounds.*—3-Hydroxyxanthone combines readily with metal and hydrogen haloids to form additive compounds. Phenyl-3-methoxyxanthenol (Decker and Fellenberg, A., 1907, i, 1065) has m. p. 125°, and its *perchlorate,* m. p. 215—217°. *3-Methoxy-9-phenylxanthenol chloride* yields a *ferrichloride,* m. p.

163—164°; *zincichloride*, m. p. 200—201°, and *mercurichloride*, m. p. 190°. *3-Methoxy-9-phenylquinoxanthenol bromide hydrobromide*, m. p. 112—115°, is orange-yellow and crystalline. The *zincibromide* of phenyl-3-methoxyxanthenol bromide has m. p. 150—155°.

3-Hydroxy-9-phenylxanthenol cannot be isolated, as it spontaneously loses water with formation of phenylfluorone. *3-Hydroxy-9-phenylquinoxanthenol chloride hydrochloride*, prepared by the action of hydrogen chloride on phenylfluorone, forms yellow crystals. On passing dry air through a solution of this substance in benzene, *3-hydroxy-9-phenylquinoxanthenol chloride*, $O<^{C_6H_4}_{C_6H_3Cl(OH)}>CPh$, m. p. 198—200°, is produced as a yellow solid, which, when treated with molecular silver, is converted into phenylfluorone. *3-Hydroxy-9-phenylquinoxanthenol bromide*, m. p. 238—240°, forms orange needles, and yields a *perchlorate*, m. p. 250°, and hydrogen sulphate, m. p. 201—202°.

V. *4-Hydroxy-9-phenylxanthenol Compounds.*—4-Methoxyxanthone has m. p. 173—174°, and yields a *stannibromide*, m. p. 125—135°; *stannichloride*, m. p. 187—188°; *mercurichloride*, m. p. 204—205°; *perchlorate*, m. p. 160°; and *hydrobromide*. *4-Methoxy-9-phenylquinoxanthenol chloride hydrochloride*, m. p. 144—145°, prepared from phenyl-4-methoxyxanthenol (Baeyer, A., 1910, i, 251), forms dark red, iridescent needles. *4-Methoxy-9-phenylxanthenol chloride*, m. p. 237—238°, is colourless, and yields coloured additive compounds; the *ferrichloride* has m. p. 147—148°; *mercurichloride*, m. p. 205—207°; and the *zincichloride*, m. p. 240—241°. The *peroxide*, m. p. 202° (decomp.), forms colourless crystals. *4-Methoxy-9-phenylquinoxanthenol bromide hydrobromide*, m. p. about 260°, separates in dark red crystals. The colourless bromide was not isolated, but the following coloured compounds were prepared: *zincibromide*, m. p. 234—235°; *mercuribromide*, m. p. 223°; *perbromide*, m. p. 188—189°.

4-Hydroxy-9-phenylxanthenol (Baeyer, *loc. cit.*) yields a *perchlorate*, m. p. 248—249°. *4-Hydroxy-9-phenylquinoxanthenol chloride hydrochloride*, m. p. 210—211°, forms dark red crystals. *4-Hydroxy-9-phenylquinoxanthenol chloride* has m. p. 200—201°, and the corresponding *bromide*, m. p. 261—262°.

4-Acetoxy-9-phenylxanthenol, m. p. 127—128°, crystallises in colourless needles; its *perchlorate* has m. p. 190°. *4-Acetoxy-9-phenylquinoxanthenol chloride hydrochloride* is an orange-red substance, which, when left in a desiccator, loses hydrogen chloride with formation of the colourless *4-acetoxy-9-phenylxanthenol chloride*, m. p. 134—135°; this compound gives a *ferrichloride*, m. p. 136—137°, and a *zincichloride*, m. p. 160—165°. *4-Acetoxy-9-phenylxanthenol peroxide*, m. p. 145—146°, forms colourless crystals.

4-Benzoxy-9-phenylxanthenol has m. p. 113—115°, and yields a *perchlorate*, m. p. 157—158°. *4-Benzoxy-9-phenylquinoxanthenol chloride hydrochloride*, m. p. 85—90° (decomp.), crystallises in yellow needles. *4-Benzoxy-9-phenylxanthenol chloride*, m. p. 111—112°, is colourless, and gives coloured additive compounds with metal haloids.

VI. *3 : 6-Dihydroxy-9-phenylxanthenol Compounds.*—*3 : 6-Dihydroxy-*

9-*phenylquinoxanthenol chloride*, $O<^{C_6H_4(OH)}_{C_6H_3Cl(OH)}>CPh$, prepared by the action of hydrogen chloride on a solution of phenyl-3-hydroxyfluorone (Kehrmann and Dengler, A., 1908, i, 1002) in nitrobenzene or alcohol, forms yellow crystals containing 1 mol. of the solvent. The pure salt darkens at 250°, but does not melt at 275°. E. G.

The Benzeins of the Xyloquinols. FRIEDRICH KEHRMANN and TH. E. STILLER (*Ber.*, 1912, **45**, 3346—3349).—By modifying the process of preparation used for quinolbenzein chloride (Kehrmann, A., 1910, i, 408) it has been found possible to condense *o*- and *p*-xyloquinols with benzaldehyde.

o-*Xyloquinolbenzein chloride* (2 : 7-*dihydroxy-9-phenyl-3* : 4 : 5 : 6-*tetramethylxanthonium chloride*), $CPh<^{C_6PhMe_2(OH)}_{C_6HMe_2(OH)}>O \cdot Cl$, can be obtained by the careful action of benzaldehyde on a mixture of *o*-xyloquinol with the corresponding quinone in the presence of a mixture of equal parts of acetic acid and sulphuric acid; the *sulphate*, which separates in reddish-brown needles, when dissolved in water and treated with concentrated hydrochloric acid precipitates the chloride in brown needles or granules. The solution of the chloride when treated with sodium acetate solution deposits the free *base* in deep brownish-violet needles, for which the analysis indicates an equimolecular combination of anhydride and carbinol base (compare Kehrmann, *loc. cit.*); *platinichloride*, reddish-brown, crystalline powder. If an alkaline solution of the free base is carefully acidified with acetic acid and shaken with ether, the latter extracts the colourless carbinol base, which with more acetic acid turns yellow on account of the formation of the oxonium salt.

p-Xyloquinol was obtained by the reduction of *p*-xyloquinone prepared by the oxidation of *p*-xylidine (compare Noelting, Witt, and Forel, A., 1886, 57). The quinol was made to condense with benzaldehyde by a process similar to that which proved successful with the ortho-isomeride; the resultant p-*xyloquinolbenzein chloride* (2 : 7-*dihydroxy-9-phenyl-1* : 4 : 5 : 8-*tetramethylxanthonium chloride*), deep red or blackish-brown crystals, on treatment in solution with sodium acetate precipitates the free *base* in bright yellow crystals; *platinichloride*, yellow crystalline powder. Unlike the analogous bases previously obtained, which dissolve in sodium hydroxide with a fleeting violet-colour, this base gives a yellow solution in sodium hydroxide.

D. F. T.

Ethers and Esters of Phthaleins and Benzeins of Orcinol. FRIEDRICH KEHRMANN [with E. ACKER, M. GUNTHER, and J. KNOP] (*Ber.*, 1912, **45**, 3505—3514).—By heating with methyl iodide, a solution of *a*-orcinolphthalein in dilute sodium hydroxide yields *a-orcinolphthalein dimethyl ether*,

$$O<^{C_6H_2Me(OMe)}_{C_6H_2Me(OMe)}>C<^{C_6H_4}_{O}{=}>CO,$$
m. p. above 365°, a white, crystalline powder, which exhibits a smaller

tendency than α-orcinolphthalein itself to form oxonium salts. By heating with methyl alcohol and concentrated hydrochloric acid, or by keeping for a month with methyl alcohol saturated with hydrogen chloride, it is converted into the dimethylated *methyl ester oxonium chloride*, $OCl \lessgtr \frac{C_6H_2Me(OMe)}{C_6H_2Me(OMe)} \gtrless C \cdot C_6H_4 \cdot CO_2Me$, reddish-brown needles, which is comparatively easily hydrolysed by water and forms with cold dilute sodium hydroxide a dark blue *substance*, probably the base in the form of a quinol or quinhydrone.

β-Orcinolphthalein is much more prone than the α-isomeride to form oxonium salts, even 10% hydrochloric acid producing an orange-red chloride. By boiling with methyl alcoholic hydrogen chloride, β-orcinolphthalein yields the *methyl ester oxonium chloride*,

$$OCl \lessgtr \frac{C_6H_2Me(OH)}{C_6H_2Me(OH)} \gtrless C \cdot C_6H_4 \cdot CO_2Me,$$
brick-red needles, whilst by treatment with methyl iodide and aqueous sodium hydroxide it yields *β-orcinolphthalein dimethyl ether*,

$$O \lessgtr \frac{C_6H_2Me(OMe)}{C_6H_2Me(OMe)} \gtrless C \lessgtr \frac{C_6H_4}{O} \gtrless CO,$$
m. p. 247—250°, colourless crystals, which like the dimethylated α-isomeride has little tendency to the formation of stable oxonium salts. The dimethyl ether and methyl alcoholic hydrogen chloride yield the *oxonium chloride*, $OCl \lessgtr \frac{C_6H_2Me(OMe)}{C_6H_2Me(OMe)} \gtrless C \cdot C_6H_4 \cdot CO_2Me$, tufts of yellowish-red needles, which dissolves in cold water without hydrolysis, forming an intensely bitter, orange-yellow solution. The solution is attacked only slowly by sodium acetate or sodium hydrogen carbonate, more rapidly by alkali carbonates or hydroxides, yielding the colourless *carbinol*, from which, immediately after its formation, the orange-yellow salts can be regenerated; the *platinichloride* and *nitrate* are described.

γ-Orcinolphthalein, which is readily freed from its isomerides by means of methyl-alcoholic hydrogen chloride, whereby the pure *chloride* is precipitated in orange-yellow leaflets with a blue shimmer, is not readily etherified or esterified.

Orcinol, benzoic acid, and anhydrous zinc chloride heated at 160—170° for six to seven hours yield a mixture of β - orcinolbenzein, (formula I), orange-red crystals, m. p. 260 — 265°, and
I.

II.

γ-*orcinolbenzein* (formula II), orange-red crystals with a bluish shimmer, m. p. about 270°, the former being isolated as the *alcoholate*, colourless prisms. A concentrated alcoholic solution of this alcoholate and concentrated hydrochloric acid yield, after short boiling, the *oxonium chloride*, $C_{21}H_{17}O_3Cl$, red crystals with a violet shimmer. α-Orcinolbenzein has not been isolated.

By heating with aqueous sodium hydroxide and methyl iodide, β-orcinolbenzein yields the *dimethyl ether*, $C_{23}H_{22}O_4$, m. p. 192—193°,

colourless crystals, which is probably the carbinol,

$$OMe \cdot C_6H_2Me \underset{O}{\overset{CPh(OH)}{<}} C_6H_2Me \cdot OMe.$$
C. S.

Fluorescein. HANS VON LIEBIG (*J. pr. Chem.*, 1912, [ii], **86**, 472—516).—A continuation of previous work (A., 1912, i, 376).

I. *Fluorescein.*—In this section the author gives further details concerning the various modifications of fluorescein, together with an account of the alkali salts of fluorescein and a discussion of their constitution.

Of the five unimolecular yellow varieties of fluorescein, the β- and δ-forms are undoubtedly single chemical individuals, although this may not be the case with the α- and γ-modifications. β-Fluorescein is readily obtained from ordinary fluorescein by boiling (1) with alcoholic hydrogen chloride, (2) with methyl alcoholic potassium hydroxide, and extracting the solution with ether, after acidification with acetic acid. It separates from ether in crystals of the composition $C_{20}H_{12}O_5, C_4H_{10}O$, and on crystallisation from ethyl acetate yields glistening, red leaflets of the βII form, $C_{20}H_{12}O_5$, which becomes red at 280—290° and has m. p. 347°.

A *monosodium* salt of fluorescein having the composition

$$2C_{20}H_{11}O_5Na, 2MeOH, H_2O$$
is produced by dissolving fluorescein in methyl-alcoholic sodium hydroxide. It crystallises in lustrous, reddish-yellow leaflets, and when heated increases enormously in volume, after the manner of Pharoah's serpents; the *monopotassium* salt, $C_{20}H_{11}O_5K, MeOH$, prepared in a similar manner, also forms reddish-yellow leaflets.

An anhydrous and alcohol-free *monosodium* salt, $C_{20}H_{13}O_5Na$, is obtained in brownish-red crystals, having a violet lustre, by heating the disodium salt of fluorescein at 220—240°, and subsequently extracting with cold water or hot alcohol; the aqueous or alcoholic extract contains δ-fluorescein, which forms with alcohol, crystals of the composition $4C_{20}H_{12}O_5, EtOH$.

The monosodium salt containing alcohol is at once decomposed by cold water into β-fluorescein and the disodium salt, whilst the alcohol-free salt is insoluble. Further, the anhydrous salt differs from the one containing alcohol in being stable towards cold mineral acids and in yielding a dark brownish-red *sulphate*, $2C_{20}H_{12}O_5, H_2SO_4$, crystallising in leaflets, when boiled with dilute sulphuric acid; the sodium salt containing alcohol yields a *sulphate* of the same composition, but crystallising in yellow leaflets.

A marked difference in the behaviour of the mono- and di-alkali salts of fluorescein has also been observed; the monoalkali salts dissolve in excess of alkali, yielding solutions from which β-fluorescein is liberated by acids, whilst the dialkali salts when subjected to the same treatment give the red variety of fluorescein.

The preparation of a *fluorescein hydrate*, $2C_{20}H_{12}O_5, H_2O$, from the yellow monosodium salt by the action of water is also described; this forms lustrous, light- to violet-red needles, which readily lose their water at the ordinary temperature and then have m. p. 347°.

II. 4:5-*Dinitrofluorescein* (compare Hewitt and Perkins, T., 1900,

77, 1324; Baeyer, A., 1910, i, 249).—The blue tetrapotassium salt of 4:5-dinitrofluorescein, which the author considers to be a p-quinonoid salt of the annexed formula, is obtained by dissolving dinitrofluorescein in aqueous alcoholic potassium hydroxide; it forms bluish-violet needles of the composition
$$C_{20}H_6O_5(NO_2)_2K_4,H_2O,EtOH,$$

and yields blue aqueous solutions, which gradually become light red on dilution, owing to hydrolysis and the formation of a red mono- or di-potassium salt. The light red solutions slowly acquire a yellow colour, a change referred by the author to the loss of water and re-formation of the pyrone ring. The rupture of the ring in these yellow solutions may be effected by alkali hydroxides, but not by sodium carbonate or ammonia.

The *hydrate* of 4:5-dinitrofluorescein, $C_{20}H_{10}O_5(NO_2)_2,H_2O$, prepared by acidifying a fresh aqueous solution of the tetrapotassium salt, crystallises from alcohol in red prisms, m. p. 211—212°.

The *ammonium* salt, $C_{20}H_8O_5(NO_2)_2,2NH_3,H_2O,MeOH$, crystallises in large dark red prisms, m. p. 234° (decomp.); it is obtained by dissolving the dinitrofluorescein in methyl-alcoholic ammonia.

When prepared by the action of potassium hydroxide on 4:5-dinitrofluorescein in aqueous solution, the *dipotassium* salt,
$$C_{20}H_8O_5(NO_2)_2K_2,$$

forms a blackish-red mass of a greenish lustre; in alcoholic solution red crystals of the composition $C_{20}H_8O_5(NO_2)_2K_2,H_2O,EtOH$ are obtained.

Addition of strong aqueous ammonia to 4:5-dinitrofluorescein gives rise to the ammonium salt of the acridine compound described by Reverdin (A., 1897, i, 226); this crystallises in red needles of the composition $2C_{20}H_{10}O_4(NO_2)_2:NH,3NH_3,6H_2O$.

For the purpose of comparison, 2:7-*dinitrofluorescein* (annexed formula) has been prepared and its behaviour towards alkalis studied. It is obtained as a light red, crystalline powder by boiling the nitrate with water, and resembles the parent compound in forming only yellow or red salts, in which the pyrone ring remains intact. The *nitrate*,
$$C_{20}H_{10}O_5(NO_2)_2,HNO_3,H_2O,$$
crystallises in yellow needles, and is formed by the action of hot 30—35% nitric acid on fluorescein.

III. *Fluorescein Ethers* (compare A., 1912, i, 376).—In addition to the previously described colourless diethyl ether of m. p. 181°, the action of ethyl sulphate on the disodium salt of fluorescein at 100° gives rise to a new colourless *diethyl ether*, crystallising in needles or prisms, m. p. 234—235°. This resembles in its general behaviour the ether of m. p. 181°, but differs from the latter compound in that it does not form oxonium salts and does not undergo reduction in acid solution. A similar difference is shown by the colourless dimethyl ethers of m. p. 255° and 197° (*loc. cit.*); in both cases the behaviour of the ethers of higher m. p. is in better agreement with the

formula $O<^{C_6H_8(OR)}_{C_6H_3(OR)}>C<^{O---}_{C_6H_4}>CO$ than that of the less fusible ethers, to which, however, this formula has already been assigned.

By hydrolysing the coloured dimethyl ether of m. p. 208° with aqueous sodium hydroxide, Fischer and Hepp (A., 1895, i, 291) obtained a coloured monomethyl ether of m. p. 262°, which closely resembles the monomethyl ether (m. p. 265°) isolated by the author (*loc. cit.*). When hydrolysed with alcoholic potassium hydroxide the dimethyl ether of m. p. 208° yields a colourless *monomethyl ether*, which probably has the constitution $O<^{C_6H_8(OMe)}_{C_6H_3(OH)}>C<^{O---}_{C_6H_4}>CO$. This separates from ethyl acetate in feathery crystals, m. p. 256—257°, forms a dark red *sodium* salt, $C_{21}H_{11}O_5Na$, and on reduction with zinc and glacial acetic acid yields a *substance*, $C_{21}H_{16}O_5$, crystallising in needles, m. p. 205—206°.

The above-mentioned sodium salt corresponds to a *monomethyl ether* of m. p. 266°, which crystallises in lustrous, yellow needles, and is formed by the action of methyl sulphate on an aqueous solution of the disodium salt of fluorescein.

The monomethyl ether of m. p. 265° (or 262°) forms a *sodium* salt of the composition $C_{42}H_{82}O_{14}Na_2$, whilst a coloured *monomethyl ether*, obtained in yellowish-white crystals, m. p. 272°, by methylating fluorescein with methyl iodide and potassium hydroxide in alcoholic solution, yields a blackish-red *sodium* salt having the composition $C_{21}H_{12}O_5Na_2,H_2O$. Since the monomethyl ethers of m. p. 262°, 265°, and 272° do not yield monosodium salts, the conclusion is drawn that these compounds cannot be represented by the formula $O<^{C_6H_4(OMe)}_{C_6H_3(:O)}>C·C_6H_4·CO_2H$.

When warmed with alcohol and hydrochloric acid and the resulting *chloride* heated at 250°, the dimethyl ether of m. p. 208° yields a small amount of the dimethyl ether of m. p. 197°. The latter compound was also obtained in an attempt to prepare a trimethyl ether of fluorescein by the oxidation of the corresponding ether of fluorescin with lead dioxide in glacial acetic acid solution.

Fluorescin trimethyl ether, $C_{23}H_{20}O_5$, prepared by warming fluorescin with strong aqueous potassium hydroxide and methyl sulphate, crystallises in small prisms or leaflets, m. p. 136°. It is accompanied by a *fluorescin monomethyl ether*, $C_{21}H_{16}O_3$, which separates with benzene (1 mol.) in crystals of m. p. 120—125°; in one instance a *substance* was obtained, which crystallised in leaflets, m. p. 204°, and resembled in its behaviour the reduction product of the dimethyl ether of m. p. 197°, mentioned below.

In addition to the dimethyl ethers of m. p. 197°, 208° and 255°, and the monomethyl ether of m. p. 266°, the action of methyl sulphate on an aqueous solution of the disodium salt of fluorescein yields the following substances : (1) a quadrimolecular *monomethyl ether*, $3C_{20}H_{12}O_5,C_{21}H_{14}O_5$, which separates from a mixture of benzene and alcohol in red or brownish-yellow crystals, which become red at 260°, or in crystals containing 4EtOH ; all three modifications have m. p. 330—333°.

(2) A *monomethyl ester*, $O<^{C_6H_8(OH)}_{C_6H_3(:O)}>C·C_6H_4·CO_2Me$, which forms

dark red crystals of a violet lustre, m. p. 282—283°. (3) A *hydrate* of the above ester, $C_{21}H_{14}O_8,H_2O$, crystallising in yellow needles, which become red and melt at 280°.

The monomethyl ester, m. p. 282—283°, is also formed by directly esterifying fluorescein with alcohol and hydrogen chloride, whilst esterification with alcohol and sulphuric acid gives rise to a monomethyl ester of m. p. 252° (compare Feuerstein and Wallach, A., 1901, i, 723).

Methylation of fluorescein by means of methyl iodide and alcoholic potassium hydroxide yields the monomethyl ethers of m. p. 256—257°, 265° and 272°, the dimethyl ether, m. p. 208°, and the quadrimolecular monomethyl ether of m. p. 330—333°.

The *hydrochloride* of the monomethyl ester of m. p. 282—283°, $C_{21}H_{14}O_5,HCl$, forms orange-yellow needles (decomp. 260°).

The monomethyl ether of m. p. 272° yields a *hydrochloride*,
$$3C_{21}H_{14}O_5,2HCl,4H_2O,$$
crystallising in brownish-yellow needles, m. p. 250°.

The products obtained by reducing the ethers of fluorescein, containing a free carboxyl group, with zinc and glacial acetic acid form crystalline compounds with benzene, which is firmly retained until about 110°, whilst those obtained from ethers in which the carboxyl group has been esterified or undergone lactone formation readily lose their benzene below 100°.

The *substance*, $C_{21}H_{16}O_5$, obtained by reducing the monomethyl ether of m. p. 257°, forms needles, m. p. 205—206°; that from the monomethyl ether of m. p. 266° separates in crystals, which become yellow and lose their benzene at 120—125°. The monomethyl ether of m. p. 265° yields a *substance*, $C_{21}H_{16}O_5,2C_6H_6$, which has m. p. 132—133° or 169—170° accordingly as it is dried at 100° or 140°. The *substance* from the monomethyl ether of m. p. 272° has m. p. 173—174°, that from the monomethyl ester of m. p. 282° separates from alcohol in small needles of the composition $C_{21}H_{16}O_5,EtOH$, m. p. 190—191°, and from benzene in crystals which melt at 83—84°, solidifies at a higher temperature, and then melts at 190—191°. The quadrimolecular monomethyl ether on reduction yields a *substance*, $3C_{20}H_{14}O_5,C_{21}H_{16}O_5,H_2O,8C_6H_6$, which loses benzene below 100°, sinters at 220°, and melts at 237—238°.

The *substance*, $C_{22}H_{18}O_5$, obtained from the dimethyl ether of m. p. 197°, forms clusters of needles, m. p. 204°; that from the dimethyl ether of m. p. 208°, stout crystals, m. p. 165°. When oxidised with lead dioxide or hydrogen peroxide in acetic acid solution the last-mentioned reduction product yields a dark red *substance* (decomp. about 200°), which forms dark brown alkali salts, and is probably produced by the oxidation of one of the resorcinol residues, as shown in the annexed formula.
The author suggests that the above results are best explained on the assumption that the ordinary red fluorescein is a polymeride, consisting probably of various di-, ter-, and quadri-molecular combinations as in the case

of resorcinolbenzein, and that the methyl ether of m. p. 330—333°, containing one methyl group to four fluorescein molecules, represents the initial stage in the methylation of the quadrimolecular form, the further methylation resulting in a more or less complete degradation into simple molecules. F. B.

Preparation of Xanthones of the Anthraquinone Series. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 251696).—Xanthones of the anthraquinone series are readily prepared by the action of condensing agents on phenyl, naphthyl, or anthraquinonyl ethers of 1-hydroxyanthraquinone-2-carboxylic acids or their substituted derivatives.

1-Phenoxyanthraquinone-2-carboxylic acid, tablets, m. p. 272°, is prepared by the fusion of 1-chloroanthraquinone-2-carboxylic acid (10 parts) with phenol (60 parts) and potassium hydroxide (25 parts) during four hours at 150°. When this product, suspended in trichlorobenzene, is treated with phosphorus pentachloride and the temperature slowly raised, it furnishes the *xanthone* (annexed formula), which separates in yellow, glistening tablets.
1-Naphthoxyanthraquinone-2-carboxylic acid, yellow tablets, m. p. 262°, is prepared in a similar manner from β-naphthol at 130—140° during two hours; the corresponding *xanthone* is obtained as greenish-yellow leaflets, m. p. above 300°; it dissolves in alkaline hyposulphite with an intense blue, and in concentrated sulphuric acid with a brownish-red, coloration. F. M. G. M.

Preparation of Condensation Products in the Anthracene Series. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 251020). — The *compound*, $C_{20}H_{10}O_3$ (annexed formula), a black powder, is obtained when anthranol and *p*-benzoquinone are boiled together in nitrobenzene -solution; it dissolves in concentrated sulphuric acid with a violet-red coloration.
The tinctorial properties of other analogous compounds obtained from *p*-benzoquinone with substituted anthranols are tabulated in the original. F. M. G. M.

Preparation of "7:7'-Diaminothioindigo." FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 252771).—When "7:7'-dinitrothioindigo" (or its substituted derivatives) is reduced with sodium sulphide or dextrose it yields the corresponding "7:7'-diaminothioindigo," a black powder, whilst "5:5'-dichloro-7:7'-dinitrothioindigo" furnishes "5:5'-*dichloro*-7:7'-*diaminothioindigo*," also a black powder. F. M. G. M.

Carpiline, a New Alkaloid from Jaborandi. ÉMILE LÉGER and FERDINAND ROQUES (*Compt. rend.*, 1912, **155**, 1088—1091*).—An

` and *J. Pharm. Chim.*, 1913, [vii], **7**, 5—13.

extract of *Pilcarpus microphyllus*, after the removal of the greater portion of the bases as their hydrochlorides, yields, on precipitating from the mother liquor, the alkaloid *pilocarpiline*, $C_{16}H_{18}O_3N_2$, m. p. 184—185°, $a_D +24°$. It is soluble in chloroform, benzene, and boiling water, and crystallises in colourless prisms. It is a feeble base, its salts with organic acids being dissociated by alcohol, whilst those with mineral acids are stable, all having a bitter taste. It gives a *hydrochloride*, $C_{16}H_{18}O_3N_2,HCl$, colourless prisms; a *sulphate*; a *platinichloride*, $(C_{16}H_{18}O_3N_2)_2,H_2PtCl_6,5H_2O$, crystalline plates, and a *methiodide*, $C_{16}H_{18}O_3N_2,MeI$, small, pale yellow prisms. The base is saturated, since its salts do not reduce potassium permanganate in the cold.

Carpiline contains a lactone group, and thus dissolves in alkali hydroxide solutions, giving compounds of the type *potassium carpilinate*, $C_{12}H_{19}O_4N_2K$, long needles, very soluble in water. The presence of an hydroxyl group is shown by the formation of an amorphous benzoyl derivative which yields *benzoylcarpiline platinichloride*,

$$[C_{16}H_{17}O_3N_2Bz]_2,H_2PtCl_6.$$
The alkaloid on oxidation with nitric acid yields benzoic acid, and on heating with water at 140° in a sealed tube, it is decomposed, giving benzaldehyde and two amorphous bases, but no hydrogen cyanide.

The alkaloid thus contains the groups $CHPh{:}$, $-OH$, $\genfrac{}{}{0pt}{}{-CO}{-O}$, and the group $C_8H_{11}N_2$, the constitution of which has yet to be elucidated. Carpiline is but slightly toxic, and has not the same effect as pilocarpine on the secretions.   W. G.

Active Principles of Catha Edulis. RALPH STOCKMAN (*Pharm. J.*, 1912, 89, 676—678).

—The leaves and twigs of this plant have long been used in Abyssinia, Somaliland, and Arabia as a stimulant-narcotic. They are now shown to contain at least three alkaloids, cathine, cathidine, and cathinine, to which the characteristic physiological action of the plant is due. By mixing a dry aqueous extract of the plant with slaked lime and extracting with dry alcohol, 0·65 and 0·75% of amorphous alkaloids are obtained from the leaves and twigs respectively. This amorphous mixture appears to consist largely of cathine and its alteration products, but no crystalline alkaloid could be isolated from it. The finely-powdered leaves were extracted completely with cold water or very dilute sulphuric or lactic acid, and the liquor made alkaline and extracted with chloroform, which removed cathine along with much impurity, from which the alkaloid was eventually separated as the sulphate. The ground, partly extracted leaves were then mixed with aqueous sodium carbonate and extracted with ether, which removed cathidine and cathinine; these were separated by taking advantage of the fact that the former is precipitated by sodium carbonate solution from aqueous solutions of its hydrochloride, whilst cathinine remains in solution along with some cathidine.

Cathine sulphate crystallises in colourless needles, is neutral in reaction, has a bitter taste, is precipitated by iodine solution, Mayer's reagent or picric acid, but not by tannin or platinic chloride. *Cathine* crystallises from chloroform and appears to be unstable in presence of

alkalis. Its physiological action on the nervous and muscular systems of the frog is similar to those exerted by morphine and caffeine ; in large doses it paralyses the terminations of the motor nerves.

Cathidine is colourless and amorphous and has a bitter taste ; it gives precipitates with the usual alkaloidal reagents. Cathidine is a muscle poison, and a slight stimulant to the nervous system.

Cathinine sulphate crystallises from water in rosettes of needles, has a bitter taste, and is precipitated by the usual alkaloidal reagents. The free base has only been obtained as a gummy or semi-crystalline mass. Cathinine is less depressant than cathine in its action on the brain, but has a greater stimulant effect on the spinal cord ; it paralyses the terminations of the motor nerves.

All three alkaloids in mammals and man act chiefly on the cerebrum and spinal cord, causing stimulation or much excitement according to the dose ; cathine produces drowsiness at first. The leaves also contain a fermentable sugar, tannin, caoutchouc, wax, and volatile oil.

Preparation of Esters of Hydroquinine. VEREINIGTE CHININ-FABRIKEN ZIMMER & Co. (D.R.-P. 251936. Compare A., 1912, i, 1013).

—It is found that the hydroquinine esters described previously can be most easily prepared in the presence of either finely divided metals of the platinum group or their colloidal solutions.

Hydroquinine ethyl carbonate (*loc. cit.*) is obtained when quinine ethyl carbonate (10 parts), 20% sulphuric acid (14 parts), and 80 parts of water are shaken with 0·1 part of colloidal palladium in 10 parts of water in an atmosphere of hydrogen under pressure until no further absorption of hydrogen is observed ; ammonium hydroxide is added, and the product extracted with ether.

Acetylhydroquinine, large, colourless crystals, m. p. 100°, is prepared in a similar way from acetylquinine, and *p*-aminobenzoylhydroquinine (*loc. cit.*) is also described.

<div align="right">F. M. G. M.</div>

Preparation of Esters of Hydrogenised Cinchona Alkaloids. VEREINIGTE CHININFABRIKEN ZIMMER & Co. (D.R.-P. 253357. Compare A., 1912, i, 1013, and preceding abstract).

—The following esters are of therapeutic value.

Hydrocinchonine ethyl carbonate, colourless, tasteless needles, m. p. 134°, is obtained when cinchonine ethyl carbonate (30 parts) dissolved in 160 parts of alcohol is shaken with 1 part of colloidal palladium in 60 parts of water until the absorption of hydrogen ceases.

Benzoylhydrocupreine, colourless crystals, m. p. 172°, is prepared from hydrocupreine.

Dibenzoylhydrocupreine, needles, has m. p. 147°, whilst *ethylhydrocupreine ethyl carbonate* is obtained from ethylhydrocupreine and ethyl chloroformate in benzene solution ; it is conveniently isolated in the form of its *salicylate,* colourless crystals, m. p. 138—142°.

<div align="right">F. M. G. M.</div>

Physostigmine [Eserine]. FRANZ EISSLER (*Biochem. Zeitsch.*, 1912, 46, 502).

—Eserine gives with diazotised sulphanilic acid in alkaline solution a red colour, which indicates the presence of a pyrrole ring.

This result is in accordance with the recent investigations of Salway (T., 1912, 101, 978).   S. B. S.

d-Lupanine. AUGUST BECKEL (*Arch. Pharm.*, 1912, 250, 691—710. Compare A., 1911, i, 743).—In continuation of previous work, the oxidation of *d*-lupanine by various agents has been investigated, and the products obtained are described.

Chromic acid in large excess oxidises lupanine to a substance containing two additional oxygen atoms, but this was produced in too small quantity to be isolated. Hydrogen peroxide gives rise to two products: the first of these gives an *aurichloride*, m. p. 214°, crystallising in needles, and the other an *aurichloride*, m. p. 188—189°, and *platinichloride*, m. p. 222—227°, crystallising in rosettes of needles. Analyses of these double salts indicate that both oxidation products have the formula $C_{15}H_{24}O_2N_2$. Potassium permanganate in presence of sodium carbonate oxidises lupanine to a *product*, $C_{15}H_{24}O_3N_2$, which was isolated as the *aurichloride*, m. p. 188—189°, and converted into the *platinichloride*, $B_2,H_2PtCl_6,2H_2O$, m. p. 219—221° (decomp.), crystallising in needles.

In the action of bromine on lupanine no fission occurs, as has been suggested by previous workers (Callsen, A., 1900, i, 186; Soldaini, A., 1905, i, 371). A perbromide of the alkaloid is first formed, and this on warming with alcohol may give rise to several different products, depending on the conditions observed. In the present series of experiments, three products melting at 228—236°, 190—210°, and 186—188° respectively were obtained. The first of these consists essentially of *ethoxylupanine dihydrobromide*, $C_{15}H_{23}ON_2 \cdot OEt,2HBr$, m. p. 227—228°, $[\alpha]_D^{15-23} -129\cdot4°$, which crystallises in colourless, slender needles from boiling alcohol, and is apparently the "substance, $C_8H_{15}ON,HBr$," described by previous workers. The specific rotation falls, slowly in the cold, more rapidly on warming, when this substance is dissolved in hydrobromic acid, but returns to its normal value when the solution is mixed with alcohol and evaporated to dryness. In presence of excess of alkali the alkaloid is dextrorotatory. The *dihydriodide*, m. p. 221—222°, forms colourless needles; the *dithiocyanate*, $C_{15}H_{23}ON_2 \cdot OEt,2HSCN,H_2O$, m. p. 172—174°, crystallises from water in colourless needles, and becomes anhydrous at 100°. The *aurichloride*, $(C_{15}H_{23}ON_2 \cdot OEt)_2,4HCl,3AuCl_3$, m. p. 145—150°, crystallises in small, yellow leaflets, and on warming in dilute hydrochloric acid gives *hydroxylupanine aurichloride*,
$$(C_{15}H_{23}ON_2 \cdot OH)_2,4HCl,3AuCl_3,$$
which sinters at 122—123°, and crystallises badly in leaflets. Ethoxylupanine does not readily reduce permanganate. Hydriodic acid converts it into a substance which was isolated as the methiodide; the latter resembles lupanine methiodide in rotation, crystalline form, and melting point, but on treatment with silver chloride and gold chloride yields an *aurichloride*, $(C_{15}H_{24}ON_2,MeCl,AuCl_3)_2,HAuCl_4$, m. p. 210°, crystallising in leaflets, whilst the aurichloride obtained in like manner from lupanine methiodide has the composition
$$C_{15}H_{24}ON_2,MeCl,AuCl_3,$$
and melts at 200—205°. The *platinichloride*, m. p. 224—226°,
crystallises in slender, brown needles, and is also abnormal in composition.

The second oxidation product, m. p. 190—210°, contained some ethoxylupanine dihydrobromide, and after the removal of this formed a crystalline mass, m. p. 192—194°, which was probably a mixture of hydrobromides.

The third product, m. p. 186—188°, on recrystallisation from boiling alcohol gave what seems to be a mixture of ethoxylupanine dihydrobromide with either hydroxylupanine hydrobromide or lupanine dihydrobromide, whilst from the mother liquor d-*lupanine dihydrobromide*, $B,2HBr,H_2O$, m. p. 188—189°, $[a]_D + 45\cdot9°$, was isolated.

T. A. H.

Morphineglucoside. CARL MANNICH (*Annalen*, 1912, **394**, 223—228).—Morphine in $N/2$-sodium hydroxide is shaken for six hours with ethereal β-acetylbromoglucose. The ethereal solution is shaken with 1% hydrochloric acid The acid extract, by treatment with ammonia, yields *morphinetetra-acetylglucoside*,

$$C_{17}H_{18}O_3N\cdot C_6H_7O_5Ac_4,H_2O,$$
m. p. 154—156°, colourless needles (*hydrochloride*, m. p. about 220° [decomp.]). By hydrolysis with $N/2$-alcoholic potassium hydroxide, the substance yields *morphineglucoside*, $C_{17}H_{18}O_3N\cdot C_6H_{11}O_5,H_2O$, m. p. 183—193°, fine needles. The glucoside, which is more conveniently obtained by the interaction of morphine, $N/2$-sodium hydroxide, and acetylbromoglucose in aqueous acetone and hydrolysis of the product, does not reduce boiling Fehling's solution, and yields dextrose and morphine by hydrolysis with $N/2$-hydrochloric acid on the water-bath. C. S.

Alkaloids of Pareira Root. MAX SCHOLTZ (*Arch. Pharm.*, 1912, **250**, 684—691. Compare A., 1899, i, 92; 1907, i, 79; 1911, i, 913, and Faltis, A., 1912, i, 796).—A reply to Faltis (*loc. cit.*) criticising his results and suggesting, as the result of new analyses, that the bebeerines are better represented by the formula $C_{17}H_{19}O_3N$ than by those previously suggested by the author and by Faltis. T. A. H.

Protopine and Cryptopine. PETER W. DANCKWORTT (*Arch Pharm.*, 1912, **250**, 590—646).—A résumé of previous papers relating to the distribution of protopine in the natural orders, *Papaveraceae* and *Fumariaceae*, and its characters and chemistry is first given. It is then shown by analogy with other papaveraceous alkaloids that protopine probably contains an *iso*quinoline group, and evidence is brought forward for the view that it contains two methylenedioxy-groups and a carbonyl group, and that the nitrogen atom has a ·CH₃ group attached to it. On these and other grounds the annexed formula is assigned provisionally to the alkaloid.
Dicentra (*Diclytra*) *spectabilis* tubers yielded 0·65% of crude alkaloid, chiefly protopine. The latter has the formula $C_{20}H_{19}O_5N$, and crystallises from a mixture of chloroform and alcohol

in colourless prisms or from ether in nodular masses : both forms melt at 207°, but the first gives with sulphuric acid a yellow coloration changing to blue, reddish-violet, and green, and with Fröhde's reagent a yellowish-olive colour changing to dirty violet, green, blue, and finally green ; the second form, on the contrary, with sulphuric acid gives a deep yellow, passing into green, dirty reddish-brown, and finally green, whilst with Fröhde's reagent it yields a yellowish-olive solution which becomes violet and finally green.

Protopine contains no hydroxyl groups or methoxyl groups, but gives Gaebel's test for dioxymethylene (A., 1910, i, 501), and the presence of the latter is confirmed by the fact that protopine, when heated under pressure with dilute sulphuric acid, yields a product giving the colour reactions of a catechol derivative. No direct evidence of the presence of a carbonyl group could be obtained. The occurrence of a $:NCH_3$ group was proved by Herzig and Meyer's method. The alkaloid is not reduced by aqueous colloidal platinum, but sodium amalgam in dilute acid converts it into *hydroprotopine*, $C_{20}H_{21}O_5N,\frac{1}{2}EtOH$, m. p. 120° (approx.) or 151—152° (dry), which crystallises from a mixture of ether and alcohol, becomes anhydrous at 100°, is easily soluble in chloroform or ethyl acetate, sparingly in alcohol and slightly in ether; the *hydrochloride* crystallises from alcohol in needles and from water in plates. On treatment with benzoyl chloride hydroprotopine is apparently first benzoylated and then partly converted by loss of H_2O into a *quaternary base*, $C_{20}H_{19}O_4N$, which has not been obtained free from the benzoylated product ; it yields a *hydrochloride*, $C_{20}H_{19}O_4N,HCl,5H_2O$, m. p. 275° (approx. decomp.), which is crystalline and from which an *aurichloride*, $B,HAuCl_4$, crystallising in reddish-brown needles is obtainable ; this hydrochloride on heating with sodium hydroxide in alcohol is converted into an isomeric *tertiary anhydro-base*, $C_{20}H_{19}O_4N$, m. p. 145°, crystallising in long needles. Both the quaternary and the tertiary anhydro-bases can be prepared in other ways from protopine and hydroprotopine ; it is believed that this series of changes from protopine to the tertiary anhydro-base takes place in the following

way : $\cdot NMe\cdot \overset{\cdot}{C}H\cdot CO\cdot \longrightarrow \cdot NMe\cdot \overset{\cdot}{C}H\cdot CH(OH)\cdot \longrightarrow$

$$\cdot (HCl)NMe\cdot CH\cdot CH(OBz)\cdot \longrightarrow$$

$$\cdot ClNMe\dot{:}C\cdot CH_2\cdot \rightleftharpoons \cdot (HO)NMe\dot{:}CH\cdot CH_2\cdot \rightleftharpoons \cdot NMe\cdot C\dot{:}CH\cdot,$$
the compound represented by the fourth formula being the "hydrochloride" of the quaternary base, and that by the sixth formula being the tertiary anhydro-base.

Methyl iodide converts protopine into the methiodide, whilst methyl sulphate transforms it into *methylprotopine methosulphate*, $C_{20}H_{19}O_5NMe\cdot SO_4Me$, which crystallises from dilute alcohol : either of these substances on heating with alkalis yields *protopinemethine*, $C_{20}H_{18}O_5NMe$, m. p. 136—137°, crystallising in pearly leaflets, which in turn furnishes a crystalline *methiodide*; this on heating with alkali hydroxides in methyl alcohol yields trimethylamine and an amorphous product.

The tertiary anhydro-base also yields a crystalline *methiodide*, m. p. 230°, and a crystalline *methine* base, m. p. 112°, which fluoresces

in ether solutions and gives a bromine additive product. The *methine-methiodide*, rosettes of needles, is not decomposed on heating with alkalis in methyl alcohol, but on treating the methine base with methyl sulphate and heating the product with sodium hydroxide in methyl alcohol an amine is evolved and a resinous vinyl derivative is formed.

Oxidation experiments with protopine and its derivatives did not afford useful results, except in the case of protopinemethine, which on treatment with potassium permanganate in acetone solution yielded a basic substance and hydrastic acid (4 : 5-methylenedioxyphthalic acid).

Cryptopine resembles protopine in its solubilities, and in physiological action, and like it contains no hydroxyl group and gives no oxime. Cryptopine contains a methylenedioxy-group, and two methoxyl groups. On reduction with sodium amalgam in dilute sulphuric acid it yields *hydrocryptopine*, m. p. 182—183°, which crystallises from ether and on treatment with benzoyl chloride gives the *hydrochloride* of a *quaternary base*. In view of this it seems likely that cryptopine differs from protopine only in containing two methoxyl groups in place of one methylenedioxy-group, but it is not clear which of the two methylenedioxy-groups of protopine is thus replaced (compare Pictet and Kramers, A., 1910, i, 502, and Brown and Perkin, P., 1891, 7, 161).   T. A. H.

Preparation of Acyl Derivatives of Theobromine   KNOLL & Co. (D.R.-P. 252641).—*Acetyltheobromine*, colourless, odourless needles with a bitter taste and m. p. 165°, is obtained by the action of acetyl chloride on a solution of sodium theobromine in chloroform or xylene.

Benzoyltheobromine forms colourless, odourless, tasteless needles, m. p. 206° (about), and is most satisfactorily prepared from silver theobromine and benzoyl chloride in toluene solution.

These compounds are of therapeutic value, and analysis indicates that they are monoacyl derivatives.   F. M. G. M.

The Chemical Constitution of Sparteine. CHARLES MOUREU and AMAND VALEUR (*Ann. Chim. Phys.*, 1912, [viii], 27, 245—391).— A résumé of work already published (compare A., 1903, i, 717 ; 1904, i, 187 ; 1905, i, 608, 609, 659, 716 ; 1908, i, 43, 44, 103, 206, 563 ; 1911, i, 319, 562 ; 1912, i, 210, 296).   W. G.

Some New Sparteine Salts. LOUIS CORBIEZ (*Chem. Zentr.*, 1912, ii, 1566 ; from *Bull. Sci. Pharmacol.*, 19, 468—480).—The following salts are described : *Basic hydrobromide*, B,HBr [$B = C_{15}H_{26}N_2$], from the basic sulphate and barium bromide, prismatic crystals, m. p. 236°, $[a]_D - 16°6'$; *di-iodide*, B,2HI + H_2O, m. p. (anhydrous) 225°, $[a]_D - 16°2'$; *normal chlorate*, B,2HClO$_3$, colourless cubes, explodes at 147°, $[a]_D - 23°12'$; *basic chlorate*, B,HClO$_3$, colourless prisms, explodes at 200—205°, $[a]_D - 16°3'$; *normal perchlorate*,

$$B,2HClO_4 + 2H_2O,$$
prisms, m. p. 78°, anhydrous, 265°, explodes over 300°, $[a]_D - 17°30'$;

basic perchlorate, $B,HClO_4$, m. p. 171°, $[a]_D$ in methyl alcohol $-17°6'$, in acetone $-16°3'$; *dichromate,* $B,H_2Cr_2O_7$, orange-yellow prisms, decomposes at 128—129°; *normal salicylate,* $B,2C_7H_6O_3 + H_2O$, pale pink prisms, m. p. 78°, $[a]_D -8°42'$.　　　　　　　　　　J. C. W.

The Constitution of Sparteine Periodide and Sparteine Perbromide. Louis Corriez (*Chem. Zentr.*, 1912, ii, 1826; from *Bull. Sci. Pharmacol.*, 1912, 19, 533—540).—The formation of sparteine periodide by the action of 12% hydrogen peroxide on sparteine di-iodide may be expressed thus: $2C_{15}H_{26}N_2 2HI + O = 2C_{15}H_{26}N_2.HI + I_2 + H_2O$; $C_{15}H_{26}N_2.HI + I_2 = C_{15}H_{26}N_2.HI,I_2$. As it would follow from the latter equation, the periodide also results when sparteine mono- or di-iodide is treated with iodine. *Sparteine perbromide,*

$$C_{15}H_{26}N_2,2HBr,Br_2 + H_2O,$$

by the action of bromine on sparteine, both dissolved in fuming hydrobromic acid, forms yellow crystals, m. p. 193°. The formation of this perbromide will show the presence of sparteine in a dilution of 1 : 10,000.　　　　　　　　　　J. C. W.

New α-Methylsparteinium Salts. Louis Corriez (*Chem. Zentr.*, 1912, ii, 1826; from *Bull. Sci. Pharmacol.*, 1912, 19, 527—532).— Starting from α-methylsparteinium hydroxide, which is obtained in aqueous solution by the action of moist silver oxide on Moureu's α-sparteine methiodide (A., 1905, i, 608), the following salts have been prepared: *Hydrochloride* of *α-sparteine methochloride,*

$$C_{15}H_{26}N_2MeCl,HCl,3H_2O,$$
transparent, hygroscopic crystals, m. p. 194°, $[a]_D -23°9'$; *hydrobromide* of *α-sparteine methobromide,* $C_{15}H_{26}N_2MeBr,HBr,2H_2O$, m. p. 216°, $[a]_D -19°2'$; *α-methylsparteinium dichromate,*

$$C_{15}H_{26}N_2Me\cdot Cr_2O_7H,H_2O,$$
orange-yellow needles, decomposes at 120°; *α-methylsparteinium perchlorate,* $C_{15}H_{26}N_2Me\cdot ClO_4$, transparent needles, decomposes at 230°; *α-methylsparteinium picrate,* $C_{15}H_{26}N_2Me\cdot C_6H_2O_7N_3$, yellow needles, m. p. 218°.　　　　　　　　　　J. C. W.

Pyrrolidonecarboxylic Acid and Polypeptides Derived from It. Emil Abderhalden and Erich Wurm (*Zeitsch. physiol. Chem.*, 1912, 82, 160—166).—Pyrrolidonecarboxyl chloride interacts with cholesterol in chloroform solution in the absence of moisture, forming *cholesteryl pyrrolidonecarboxylate,* $C_{26}H_{43}\cdot O\cdot CO\cdot CH{<}^{CH_2\cdot CH_2}_{NH-CO}$. This crystallises in colourless, matted needles, which sinter at 199—203°, m. p. 205°.

dl-*Pyrrolidonecarboxyl-d-alanine ester* crystallises in rosettes of needles, m. p. 125·5° (corr.), $[a]_D^{20} -46·42°$.

dl-*Pyrrolidonecarboxyl-dl-leucine ester* separates in prisms, m. p. 115—117° (corr.).　　　　　　　　　　E. F. A.

Chalkones and Hydrochalkones. III. Guido Bargellini and E. Martegiani (*Gazzetta*, 1912, 42, ii, 427—432. Compare this vol., i, 59).—The authors have applied the mode of reduction previously

described to compounds analogous to chalkones, but containing pyrrole and furan rings, instead of benzene rings. In all cases only two atoms of hydrogen were added, and the rings were not attacked; the experiments were conducted in alcoholic solution (compare Willstätter and Hatt, A., 1912, i, 545).

2-Cinnamoylpyrrole (compare Ciamician and Dennstedt, A., 1885, 378) is conveniently prepared by keeping a mixture of 2-acetylpyrrole and benzaldehyde in the presence of potassium hydroxide in aqueous-alcoholic solution. The *dihydro*-derivative, $C_{13}H_{13}ON$, forms colourless needles, m. p. $70-71°$. It dissolves in concentrated sulphuric acid, giving a colourless solution.

2-mp-*Methylenedioxycinnamoylpyrrole*, $C_{14}H_{11}O_3N$, is obtained by keeping 2-acetylpyrrole and piperonaldehyde in the presence of potassium hydroxide in aqueous-alcoholic solution. It dissolves in concentrated sulphuric acid, giving an intense red coloration. On reduction it yields a *dihydro*-derivative, $C_{14}H_{13}O_3N$, which forms colourless needles, m. p. $84-85°$, and dissolves in concentrated sulphuric acid, giving a colourless solution.

Furfurylidenepaenol (compare Courant and von Kostanecki, A., 1907, i, 75) gives a *dihydro*-derivative, $C_{14}H_{14}O_4$, which forms colourless needles, m. p. $72-73°$.

2-*Furfurylideneacetylpyrrole*, $C_{11}H_9O_2N$, crystallises in yellow needles, m. p. $130-131°$; it dissolves in concentrated sulphuric acid, giving an intense red coloration. Its *dihydro*-derivative, $C_{11}H_{11}O_2N$, crystallises in colourless needles, m. p. $70-71°$.   R. V. S.

Preparation of 2-Indolecarboxylic Acid and 2:3-Dihydroxy-quinoline from Oxal-*o*-toluidic Acid. Indole Syntheses. II. WALTER MADELUNG (*Ber.*, 1912, **45**, 3521—3527. Compare A., 1912, i, 499).—The synthesis of indole compounds recently described (*loc. cit.*) fails with the application of formyl derivatives, and so the direct synthesis of indole itself in this way fails. By the use of oxal-*o*-toluidic acid, however, the action proceeds in the normal manner with the formation of the expected indolecarboxylic acid, which by careful distillation can be converted into indole (Weissgerber, A., 1911, i, 155).

Oxal-*o*-toluidic acid is conveniently obtained by heating a mixture of equal quantities of *o*-toluidine and anhydrous oxalic acid for an hour at a temperature not exceeding $130°$; the concentrated solution of the toluidine salt of the acid on treatment with the necessary quantity of dilute sulphuric acid gives a thick deposit of the free acid. On evaporating the solvent from an alcoholic solution of sodium ethoxide and potassium oxal-*o*-toluidate and raising the temperature of the resultant intimate mixture to $340-350°$, reaction takes place with the formation of two products, one of which can be easily dissolved out with benzene. This substance by m. p. $199-202°$, and by its yielding indole on heating was evidently indolecarboxylic acid.

The sparingly soluble constituent, prisms, m. p. $257-258°$, gives a *diacetyl* derivative, needles, m. p. $211°$, and produces with ferric chloride a bluish-green coloration; it is inappreciably attacked by phosphorus pentachloride even at $140°$, the only result being a minute

quantity of a *substance*, m. p. 70—90°. It is highly probable that this second constituent of the mixture produced in the original synthesis is 2 : 3-*dihydroxyquinoline*. This decision is at variance with tho published results of Friedländer and Weinberg (A., 1883, 351), who ascribe a considerably higher m. p. and no ferric chloride coloration. A repetition of Friedländer and Weinberg's method of preparation, namely, fusion of 3-chloro-2-hydroxyquinoline with potassium hydroxide, showed that under certain conditions the dihydroxyquinoline, m. p. above 300°, of these investigators becomes a subsidiary product, whilst a by-product mentioned by them becomes the main resultant substance, identical with the author's dihydroxyquinoline. The correctness of this view, that the earlier description of dihydroxyquinoline is a mistake, is confirmed by the action of phosphorus pentachloride, which converts the substance (m. p. above 300°) into a compound which sinters at 102°, decomposes at a higher temperature, and is quite distinct from 2 : 3-dichloroquinoline.   D. F. T.

Preparation of Derivatives of 2-Phenylquinoline-4-carboxylic Acid and its Homologues. CHEMISCHE FABRIK AUF AKTIEN VORM. E. SCHERING (D.R.-P. 252643).—2-Phenylquinoline-4-carboxylic acid and its homologues, although of therapeutic value, have the disadvantage of a bitter taste; this drawback is absent in the amides which have now been prepared.

The *chloride* of 2-phenylquinoline-4-carboxylic acid is a yellow powder, m. p. 230°, and the *amide*, glistening, colourless, hair-like needles, m. p. 195°; whilst the *amide* of 2-phenyl-6-methylquinoline-4-carboxylic acid forms glistening needles, m. p. 257°.

F. M. G. M.

Salts of Acridine, Pyridine, and Quinoline. LEE H. CONE (*J. Amer. Chem. Soc.*, 1912, **34**, 1695—1706).—The object of this work was to study the analogy between the derivatives of the triphenylcarbinols and xanthenols, on the one hand, and those of the acridols on the other, and to show that this analogy extends to the salts of pyridine and quinoline. It has been found that the haloids of phenylacridol, pyridine, and quinoline react with silver to form silver haloids and unsaturated compounds, similar to triphenylmethyl, which readily absorb oxygen. The ammonium salts, such as phenylbenzyldimethylammonium chloride and tetramethylammonium iodide, do not react in this way. The conclusion is therefore drawn that the salts of acridine, pyridine, and quinoline are probably quinocarbonium salts and not ammonium salts, as has been generally assumed.

When diphenylacridol chloride (Gomberg and Cone, A., 1910, i, 59) is suspended in nitrobenzene and treated with molecular silver, a double *silver* salt, $C_{25}H_{18}NCl,AgCl$, is produced, together with an unsaturated compound which absorbs oxygen to form a peroxide, thus: (1) $C_{25}H_{18}NCl + Ag = C_{25}H_{18}N- + AgCl$; (2) $C_{25}H_{18}NCl + AgCl = C_{25}H_{18}NCl,AgCl$; (3) $2C_{25}H_{18}N- + O_2 = (C_{25}H_{18}N)_2O_2$.

When 5-*phenyl*-10-*methylacridol chloride hydrochloride*,

$$NMe\underset{C_6H_4\underline{\quad\quad}}{\overset{C_6H_4(Cl,HCl)}{<}}\hspace{-0.3em}>CPh,$$
is heated at 90—100° and a current of air passed through it, it is converted into the *chloride*, $NMe{<}^{C_6H_4Cl}_{C_6H_4}{>}CPh$, which, on being treated with molecular silver, yields a double *silver* salt,

$$C_{20}H_{16}NCl,AgCl,$$
and an unsaturated compound which absorbs oxygen.

If pyridine methyl iodide is shaken with nitrobenzene and excess of silver, a similar reaction occurs with formation of a double iodide and an unsaturated compound which absorbs oxygen. Quinoline methiodide behaves in the same way.   E. G.

Acridine Derivatives. II. Analogue of *apo*Safranone in the Acridine Series. FRIEDRICH KEHRMANN and ZD. MATUSINSKY (*Ber.*, 1912, **45**, 3498—3505).—2-Hydroxy-5-phenylacridine is best obtained by heating, without stirring, an intimate mixture of *m*-hydroxy-diphenylamine, benzoic acid, and zinc chloride at 180—200°, and finally at 210°, for half an hour at each temperature; a crystalline by-product is also obtained, the removal of which presents some difficulty. The hydroxyphenylacridine crystallises from hot saturated solutions in straw-yellow needles, m. p. 264°, and at the ordinary temperature in brick-red prisms, m. p. about 135°, changing to the yellow modification. On the contrary, the yellow form changes to the red by long keeping at the ordinary temperature. The suggestion is offered that the two modifications have an ortho- and a para-quinonoid constitution respectively:

$$C_6H_4{<}^{CPh}_{-N}{>}C_6H_3 \cdot OH \text{ and } C_6H_4{<}^{CPh}_{NH}{>}C_6H_3 \vdots O.$$
2-Acetoxy-5-phenylacridine, m. p. 151°, pale-yellow leaflets, reacts with methyl sulphate in nitrobenzene at 140—150° to form *2-acetoxy-5-phenyl-10-methylacridinium methosulphate*,

$$CPh{<}^{C_6H_4-}_{C_6H_3(OAc)}{>}NMe \cdot SO_4Me,$$
citron-yellow needles, from which a *chloride*, *bromide*, *iodide*, and *platinichloride*, yellow to orange-red, crystalline salts, can be prepared.
By warming a dilute aqueous solution of one of these salts with sodium hydroxide on the water-bath. C-*phenyl*-N-*methyl*iso*acridone* (annexed formula), m. p. 231°, brownish-red or dark red needles, is obtained. This substance sublimes unchanged, does not react with alkalis, but forms with acids crystalline, red and yellow salts which are completely hydrolysed by water. It yields salts of the preceding acetoxyphenylmethylacridinium base by prolonged keeping with acetic anhydride and treatment of the resulting solution with metallic salts, and is converted by methyl sulphate in nitrobenzene at 150° into 2-*methoxy-5-phenyl-10-methylacridinium methosulphate*, citron-yellow needles, from which the corresponding *chloride*, *iodide*, *platinichloride*, and *dichromate* have been prepared.   C. S.

Action of Phthalic Anhydride on Some Pyrrole Derivatives. HANS FISCHER and FR. KROLLPFEIFFER (*Zeitsch. physiol. Chem.*, 1912, **82**, 266—272).—The trisubstituted pyrroles are at

present characterised as picrates or as the azo-dyes formed with diazobenzenesulphonic acid. They also form characteristic crystalline phthalides when heated with phthalic anhydride and acetic acid in sealed tubes at 180—190°.

3-*Acetyl-2 : 4-dimethylpyrrolephthalide,*

$$C_6H_4 {\scriptstyle <} {\overset{\textstyle CO \cdot C : OMe}{\underset{\textstyle CO \cdot N \cdot CMe}{}}} {\scriptstyle >} C \cdot COMe,$$
crystallises in faintly yellow-coloured needles, m. p. 183°. On heating with potassium hydroxide it is converted into the corresponding *acid*, which crystallises in slender, colourless needles, m. p. 176—178°.

Cryptopyrrolephthalide separates in brownish-yellow needles, m. p. 169°; the corresponding acid has m. p. 195° (decomp.).

Phonopyrrolecarboxylic acid phthalide forms faintly yellow-coloured needles, m. p. 225—226°; it can be prepared easily from syrupy phonopyrrolecarboxylic acid.

Haemopyrrolephthalide forms yellow prisms, m. p. 116°.

Tetramethylpyrrole and phthalic anhydride yield a *trimethylpyrrolephthalide*, crystallising in stunted, yellow prisms, m. p. 205°. The *acid* obtained on heating with potassium hydroxide has m. p. 204° (decomp.).   E. F. A.

The Methylation of Gallocyanin, Pyrogallin, and Azurin. FRIEDRICH KEHRMANN and A. BEYER (*Ber.*, 1912, **45**, 3338—3345).— The preparation of oxonium salts analogous to those obtained from resorufin (Kehrmann and Vogt, A., 1910, i, 409) offers in the case of the above substances considerably more difficulty.

The starting substances, gallocyanin, its methyl ester, pyrogallin (m. p. 240—241°), and azurin were first carefully purified and their properties re-examined.

Gallocyanin, on methylation in sodium hydroxide solution with methyl sulphate, gave the phenolic *ether*, $O {\scriptstyle <} {\overset{\textstyle C_6H(OMe)(CO_2H)}{\underset{\textstyle O \longrightarrow C_6H_8(NMe_2)}{}}} {\scriptstyle >} N,$ deep blue powder, m. p. 203—204°, which forms salts with acids and bases; the solution of this substance in fuming sulphuric acid when diluted changes colour from red to blue, and again to red, indicative of the existence of tri-, di-, and mono-acid salts. Simultaneously with the above ether there is obtained *dimethylgallocyanin,*

$$O {\scriptstyle <} {\overset{\textstyle C_6H(OMe)(CO_2Me)}{\underset{\textstyle O \cdot C_6H_8(NMe_2)}{}}} {\scriptstyle >} N,$$
which is better obtained, however, by the action of methyl sulphate on the methyl ester of gallocyanin; it forms prisms with a bronze lustre, m. p. 197°, is insoluble in alkalis, but with acids gives crystalline salts; the solution in fuming sulphuric acid on dilution gives the same series of colour changes as the phenolic ether; *platinichloride*, crystalline.

Methyl sulphate acts on an alkaline solution of pyrogallin, giving a phenolic *ether*, $O {\scriptstyle <} {\overset{\textstyle C_6H_2(OMe) \longrightarrow}{\underset{\textstyle O \cdot C_6H_8(NMe_2)}{}}} {\scriptstyle >} N,$ prisms with a green lustre, m. p. 199—200°. The solution in fuming sulphuric acid shows the usual colour changes on dilution.

Azurin can be methylated by heating with methyl alcohol containing a little hydrochloric acid, forming the *ester*, $O<{C_{10}H_2(CO_2Me)= \atop O \cdot C_6H_3(NMe_2)}>N$, prisms with a metallic lustre, m. p. 190°; the solution in concentrated mineral acid changes from a blue to a red colour on dilution.

<div align="right">D. F. T.</div>

Preparation of Anthrapyridonecarboxylic Acids. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 250885).—When the compound, $C_6H_4<{CO \atop CO}>C_6H_3 \cdot NH \cdot CO \cdot CH_2 \cdot CO_2Et$ obtained by heating together molecular proportions of ethylmalonyl
CO₂H·C·CO·NH
‖
$C_6H_4<{CO \atop CO-}$

chloride and α-aminoanthraquinone at 200° is boiled with aqueous sodium hydroxide it yields *anthrapyridonecarboxylic acid*, $C_{17}H_9O_4N$ (annexed formula); this compound exhibits a yellow fluorescence when dissolved in concentrated sulphuric acid.

The analogous *compound*, $C_{17}H_{10}O_4N_2$, prepared from 1 : 4-diamino-anthraquinone is a red powder; and the *compound* from 4-chloro-1-aminoanthraquinone an orange-yellow powder. F. M. G. M.

Preparation of Anthraquinone Derivatives. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252839).—The condensation of aldehydes with *o*-diaminoanthraquinones has been recorded; this action is now found to take place with 1-amino-2-hydroxyanthra-quinone or with 1-aminoanthraquinone-2-thiol, yielding compounds of the general formulæ :

$$A<{NH_2 \atop OH} \rightarrow A<{N \atop O}>CR. \qquad A<{NH_2 \atop SH} \rightarrow A<{N \atop S}>CR.$$
The following *compounds* are described: from benzaldehyde with (1) 1-amino-2 : 4-dihydroxyanthraquinone, an orange, crystalline powder; (2) with 2 : 4-diamino-1-hydroxyanthraquinone, brown crystals; (3) with 3-amino-1 : 2-dihydroxyanthraquinone, orange needles; (4) with 1 : 5-diamino-2:4:6:8-tetrahydroxyanthraquinone; (5) with 1-aminoanthraquinone-2-thiol; from 1-amino-2 : 4-dihydroxy-anthraquinone with paraformaldehyde, whilst the *anthra*-1 : 2-*oxazole* rom 1-amino-2-hydroxyanthraquinone forms yellow crystals.

<div align="right">F. M. G. M.</div>

1-Amino-2-methylanthraquinone-α-quinolines. ALFRED SCHAAB-SCHMIDT and ALEX. STAHLSCHMIDT (*Ber.*, 1912, 45, 3452—3456).—These substances have been prepared in order to ascertain what influence the presence of a quinoline nucleus has on the colour of the already intensely coloured 1-aminoanthraquinone. The dinitration of 2-methylanthra-quinone by concentrated nitric and sulphuric acids yields a mixture of 1 : 5-*dinitro-2-methylanthraquinone*, m. p. 251—252°, and 1 : 8-*dinitro-2-methylanthraquinone*, m. p. 189—190°, which is separated by the sparing solubility of the former in boiling glacial acetic acid. The two substances, the orientation of the nitro-groups in which is assumed from analogy to the course of the nitration of anthraquinone,

are reduced by alkaline sodium sulphide to 1 : 5-*diamino-2-methyl-anthraquinone*, m. p. 201—202°, red needles, and 1 : 8 *diamino-2-methylanthraquinone*, m. p. 206—208°, brownish-red needles, from which the quinolines are obtained by the Skraup method. 1-*Amino-2 methyl-anthraquinone-5-quinoline* (formula I), m. p. 206—207, reddish-brown
(I.)   (II.)

needles, dissolves in concentrated sulphuric acid with a brownish-yellow colour changing to blue by dilution with water. 1-*Amino-2-methylanthra-quinone-8 quinoline* (formula II), m. p. 100°, reddish-brown crystals, forms violet solutions in dilute mineral acids.   C. S.

The Purification and Separation of Anthraquinoneacridones from By-products. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 253090).—*Bromoanthraquinoneacridone*, a yellowish-red powder (prepared from anthraquinoneacridone), has m. p. above 300°, and is conveniently purified by isolation in the form of its *sulphate*, whilst the action of sulphuryl chloride on anthraquinoneacridone furnishes a mixture of two isomeric *chloroanthraquinoneacridones*.   F. M. G. M.

[Preparation of 4:4'-Diamino-2:2'-dimethyldiphenyl-methane.] FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 252916).—*4 : 4'-Diaminodiphenylmethane* prepared from *m*-toluidine crystallises from hot water in colourless needles, m. p. 123°; the solution of its hydrochloride gives a violet coloration with ferric chloride, and when fully diazotised and combined with *a*-naphthol-5-sulphonic acid (2 mols.) furnishes a brownish-red azo-colouring matter. F. M. G. M.

Preparation of Aminobenzoyl Derivatives of Aminobenzoyl-7-amino-1-naphthol-3-sulphonic Acid. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252159).—The tinctorial properties of the compounds obtained by the action of nitrobenzoyl haloids on aminobenzoyl-7-amino-1-naphthol-3-sulphonic acid and subsequent reduction have been recorded; it is now found that these compounds can be obtained by the combination of an aminobenzoic acid with a nitrobenzoyl haloid, followed by condensation with 7-amino-1-naph-thol-3-sulphonic acid and subsequent reduction.   F. M. G. M.

Action of Hydroxylamine and of Phenylhydrazine on Urethanobenzylacetylacetone and on Ethyl Urethanobenzyl-acetoacetate. G. BIANCHI (*Gazzetta*, 1912, 42, ii, 496—512. Compare A., 1912, i, 542; Bianchi and Schiff, A., 1911, i, 977).—By the action of hydroxylamine on ethyl urethanobenzylacetoacetate, a stable

compound, $C_{16}H_{22}O_5N_2$, is obtained, which crystallises in colourless needles, m. p. 185° (sintering a few degrees previously). This compound is the normal *oxime*,

$$OH \cdot N\hspace{-0.3em}:\hspace{-0.3em}CMe \cdot CH(CO_2Et) \cdot CHPh \cdot NH \cdot CO_2Et.$$

The action of hydroxylamine on urethanobenzylacetylacetone yields two compounds. One, which forms heavy, prismatic crystals, m. p. 175° (decomp.), has the composition $C_{15}H_{20}O_4N_2$, and is the *monoxime*, $OH \cdot N\hspace{-0.3em}:\hspace{-0.3em}CMe \cdot CH(COMe) \cdot CHPh \cdot NH \cdot CO_2Et$; it is unstable and is obtained with difficulty. The other compound forms large, prismatic crystals, m. p. 94—95°; it is readily obtained and very stable; it has the composition $C_{15}H_{18}O_3N_2$ required by 4-*urethano-benzyl*-2 : 5-*dimethyl*isooxazole,

$$O \big\langle {\substack{CMe\hspace{-0.2em}:\hspace{-0.2em}C \cdot CHPh \cdot NH \cdot CO_2Et \\ N =\!\!= CMe}}$$

. The oxime readily changes into the *iso*oxazole derivative.

[With MANLIO ROCCHI.]—The action of phenylhydrazine on urethanobenzylacetylacetone and on ethyl urethanobenzylacetoacetate yields in each case the normal monophenylhydrazone. *Urethano-benzylacetylacetonephenylhydrazone*, $C_{21}H_{25}O_3N_3$, crystallises in groups of needles, m. p. 149—150° (decomp.). *Ethyl urethanobenzylaceto-acetatephenylhydrazone*, $C_{22}H_{27}O_4N_3$, crystallises in groups of needles, m. p. 136—137°. R. V. S.

Benzoylation of Aminourazole. ROBERT STOLLÉ and K. KRAUCH (*Ber.*, 1912, **45**, 3307—3311).—By the action of benzoyl chloride on aminourazole in presence of pyridine there are obtained a dibenzoylaminourazole, $C_2H_2O_2N_4(COPh)_2$, a tribenzoylaminourazole, and what was considered to be a tetrabenzoyl derivative. The last did not give aminourazole on hydrolysis, yielding instead a dibenzoyl derivative which proved to be identical with the benzoylhydrazi-carbonyl, $COPh \cdot N \big\langle {\substack{NH \\ CO}}$, obtained by Diels and Wagner (A., 1912, i, 511; compare Diels and Okada, *ibid.*, 918) by the action of alkali on chlorobenzoylcarbamide. The supposed tetrabenzoyl derivative is, therefore, *dibenzoylhydrazicarbonyl*, for which the symmetrical formula $CO \big\langle {\substack{N \cdot COPh \\ N \cdot COPh}}$ is considered most probable.
Dibenzoylaminourazole crystallises in needles, m. p. 201°, and yields aminourazole on hydrolysis.

Tribenzoylaminourazole forms tiny needles, m. p. 234°.

Dibenzoylhydrazicarbonyl has m. p. 130°. With sodium ethoxide, ethyl dibenzhydrazidoformate, m. p. 130° (Stollé and Benrath, A., 1904, i, 935), is obtained. On heating the carbonyl at 280°, 2:5-di-phenyl-1 : 3 : 4-oxadiazole is formed. E. F. A.

Constitution of the Compound from Benzoyl Chloro-carbamide and Alkali. PETER J. SCHESTAKOV (*Ber.*, 1912, **45**, 3273—3274. Compare Diels and Okada, A., 1912, i, 918; Diels and Wagner, A., 1912, i, 511).—A claim for priority. Schestakov, Kind,

and Lebedev (*J. Russ. Phys. Chem. Soc.*, 1908, **40**, 330) have prepared the compound described as benzoyl hydrazicarbonyl,

$$COPh \cdot N {<}^{NH}_{CO},$$
by Diels and Okada, and ascribe to it the formula $COPh \cdot N{<}^{N}_{C \cdot OH}.$

E. F. A.

Preparation and Properties of 5-Aminoquinoline-6 carboxylic Acid and Certain Related Compounds. MARSTON T. BOGERT and HARRY LINN FISHER (*J. Amer. Chem. Soc.*, 1912, **34**, 1569—1576).—This investigation was undertaken with the object of preparing an aminocarboxylic acid of the anthranilic type from which substances belonging to new heterocyclic systems might be obtained.

A method is described for the preparation of 5-nitro-6-methylquinoline (Noelting and Trautmann, A., 1891, 325). 5-Amino-6-methylquinoline has m. p. 135° (corr.); attempts to oxidise this compound to 5-aminoquinoline-6-carboxylic acid were not successful.

5-*Aminoquinoline*-6-*carboxylic acid*, $NH_2 \cdot C_9NH_5 \cdot CO_2H$, m. p. 218·5° (decomp.), obtained in 30% yield by boiling 5-nitro-6-methylquinoline with alcoholic potassium hydroxide, crystallises in red nodules; it yields brown, amorphous precipitates with barium chloride, calcium chloride, cadmium iodide, copper sulphate, indium chloride, and mercuric chloride, and green precipitates with nickel chloride and silver nitrate. The *hydrochloride* has m. p. 264·7°. The *methyl* ester crystallises in bright red needles with $2H_2O$; the anhydrous form, m. p. 245° (corr.), is an amorphous, scarlet powder. 5-*Acetylamino*-6-*quinolinecarboxylic acid*, m. p. 237° (corr., decomp.), obtained by the action of acetic anhydride on the acid, forms slender, yellow needles; by prolonged

heating with acetic anhydride it is converted into the *lactam*, $C_9H_5{<}^{CO}_{NAc}$

or $C_9H_5{<}^{CO \cdot O}_{N=CMe}$, m. p. 190° (uncorr.), which crystallises in nearly colourless needles, and reacts with primary amines to form naphtha*iso*triazines (this vol., i, 106). 5-*Benzylideneaminoquinoline*-6-*carboxylic acid*, $CHPh:N \cdot C_9NH_5 \cdot CO_2H$, m. p. 221·4° (corr., decomp.), forms rosettes of needles. 5-*Hydroxyquinoline*-6-*carboxylic acid*, m. p. 211·7° (corr., decomp.), is obtained as a dark green precipitate by the action of nitrous acid on the hydrochloride of the amino-acid, and crystallises in rosettes of brown needles; it yields green, amorphous precipitates with barium chloride, zinc chloride, cadmium iodide, copper sulphate, mercuric chloride, and silver nitrate.

E. G.

Preparation of Condensation Products from 1-Chloro-2:4-dinitrobenzene with the Leucoindophenols derived from Carbazole. LEOPOLD CASSELLA & Co. (D.R.-P. 252642).—Compounds having the annexed general formula, where R is hydrogen or alkyl, are obtained by the action of 1-chloro-2:4-dinitrobenzene on the leucoindophenols prepared from *p*-nitrosophenol with carbazoles. The *compounds* thus obtained
from the indophenols of carbazole with p-nitrosophenol (glistening, coppery leaflets, m. p. 190°) and from N-ethylcarbazole with p-nitrosophenol (small, reddish-brown needles, m. p. 223°) are described.

<div style="text-align:right">F. M. G.</div>

Constitution of isoQuinoline Red. II. EDUARD VONGERICHTEN and W. HOMANN (*Ber.*, 1912, **45**, 3446—3452. Compare A., 1910, i, 201).—The basic substance, $C_{19}H_{12}ON_2$, obtained together with benzaldehyde or benzoic acid by the oxidation of *iso*quinoline red by potassium dichromate and dilute sulphuric acid, proves to be 2-*quinolyl*-2-*isoquinolyl ketone*, $C_9NH_6 \cdot CO \cdot C_9NH_6$. It yields *iso*quinoline and quinaldic acid by heating with concentrated potassium hydroxide. It forms a *methiodide*, $C_{20}H_{15}ON_2I$, decomp. about 120°, and an *ethiodide*, decomp. about 160°. By treatment with aqueous silver sulphate, the methiodide yields a solution of the methosulphate, which is treated

with sodium hydroxide and potassium ferricyanide, whereby quinaldic acid and N-methyl-*iso*quinolone are produced. By reduction with alcoholic ammonium sulphide at 200°, *iso*quinoline red yields benzyl mercaptan and a *substance*, m. p. 231°, golden-yellow leaflets.
The preceding statements, together with the fact that the quinaldine cannot be replaced by lepidine or any other methylated quinoline in the preparation of *iso*quinoline red, lead to the annexed formula for this substance.

<div style="text-align:right">C. S.</div>

Octachloroindigotin and Some Derivatives of Tetrachloro-anthranilic and Tetrachlorophthalic Acids. WILLIAM R. ORN-DORFF and E. H. NICHOLS (*Amer. Chem. J.*, 1912, **48**, 473—500).—By the action of dimethylaniline on the product of the diazotisation of tetrachloroanthranilic acid (Villiger and Blangey, A., 1909, i, 922), *dimethylaminobenzeneazotetrachlorobenzene-o-carboxylic acid*,

$$NMe_2 \cdot C_6H_4 \cdot N:N \cdot C_6Cl_4 \cdot CO_2H,$$
is obtained as a brilliant red substance. The *acetyl* derivative of 5:6:7:8-tetrachloro-3:4-dihydro-2:4-benzoxaz-1-one (Villiger and Blangey, *loc. cit.*), m. p. 166·5° (corr.), crystallises in colourless, rectangular plates. When tetrachlorophenylglycine-o-carboxylic acid (A., 1910, i, 382) is boiled with acetic anhydride, *tetrachloroacetyl-indoxylic acid*, $C_6Cl_4 \begin{smallmatrix} NAc \\ C(OH) \end{smallmatrix} C \cdot CO_2H$, m. p. 225° (corr.), is produced as a pale yellowish-green, crystalline powder; its *silver* salt forms light greyish-green needles containing $1H_2O$. If fused sodium acetate is used with the acetic anhydride, the reaction proceeds further, and mono- and di-acetyl derivatives of tetrachloroindoxyl are produced; the *acetyl* derivative, $C_6Cl_4 \begin{smallmatrix} NAc \\ C(OH) \end{smallmatrix} CH$, m. p. 195° (uncorr.), crystallises in white, slender, microscopic prisms; the *diacetyl* derivative, $C_6Cl_4 \begin{smallmatrix} NAc \\ C(OAc) \end{smallmatrix} CH$, m. p. 167° (uncorr.), forms very pale blue, rectangular prisms. On heating a solution of tetrachloroacetylindoxylic

<div style="text-align:right">h 2</div>

acid in aqueous ammonia, *octachloroindigotin*,

$$C_6Cl_4 \underset{CO}{\overset{NH}{<}} > C:C \underset{NH}{\overset{CO}{<}} > C_6Cl_4,$$
is produced as a purple, amorphous precipitate, which, when heated in a current of air at 360°, sublimes in small, rhombic plates.

Villiger's statement (A., 1909, i, 931) that dichlorophthalylhydroxyl-amine is converted into dichloroanthranilic acids by heating it with sodium carbonate solution, suggested that tetrachloroanthranilic acid might be similarly obtainable from the corresponding tetrachloro-phthalylhydroxylamine (tetrachlorophthaloxime), and the following experiments were, therefore, carried out. When tetrachlorophthalic anhydride is heated with a solution of hydroxylamine in methyl alcoho *tetrachlorophthaloxime hydroxide methyl ether,*

$$CO \underset{C_6Cl_4}{\overset{O}{<}} > C(OH) \cdot NH \cdot OMe,$$
m. p. 2'6—247° (corr., decomp.), is produced. If the tetrachlorophthalic ar¹...de is heated with an aqueous solution of hydroxylamine, *tetrachlorophthaloxime hydroxide,* $CO \underset{C_6Cl_4}{\overset{O}{<}} > C(OH) \cdot NH \cdot OH$, m. p. 254° (corr.), is obtained, which crystallises in nearly white prisms. When this substance is heated at 50° or left in a vacuum desiccator with phosphoric oxide, it loses water and becomes converted into *tetra-chlorophthaloxime,* $C_6Cl_4 \underset{C(:NOH)}{\overset{CO}{<}} > O$, which forms lemon-yellow prisms; the *sodium* salt is described; the *acetyl* derivative, m. p. 176° (corr.), crystallises in white needles.   E. G.

[**Preparation of Halogenated Derivatives of Indigoid Com-pounds.**] BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 252387).—The bisulphite compounds of indigoid derivatives are readily halogenated, yielding *compounds* with a high halogen content. The bromination of the bisulphite compounds obtained from isatin chloride and carbazole, and of that from indoxyl-red,

$$C_6H_4 \underset{CO-}{\overset{NH}{<}} > C:C \underset{C_6H_4}{\overset{-CH}{<}} > N,$$
is described, and other compounds which can be similarly treated are mentioned.   F. M. G. M.

Preparation of Condensation Products from Indigotin, its Homologues or Halogen-substitution Products. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 250744).—When indigotin, its homologues, or halogen-substitution products are heated at 150—200° in the presence of zinc chloride with benzoic anhydride (or substituted benzoic anhydrides), condensation products are formed which find employment in the preparation of dyes.

Indigotin (10 parts), zinc chloride (10 parts), and benzoic anhydride (40 parts) at 150—160° yield a yellow, crystalline *compound*, m. p. 357°.

The following analogous *compounds* are also described: from di-bromoindigotin with benzoic anhydride, yellow crystals, m. p. 340° (about) from indigotin with *p*-toluic anhydride, pale yellow crystals,

m. p. 330°; from the same with dibromoindigotin, m. p. above 330°: from indigotin with p-methoxybenzoic anhydride, yellow crystals, m. p. 320°; and from indigotin with o-chlorobenzoic anhydride, m. p. above 340°. These compounds dissolve in concentrated sulphuric acid with red colorations, but are insoluble in alkaline hyposulphite; they can be prepared in the presence of an indifferent solvent or by the fusion of the constituents. F. M. G. M.

Buchner's Pyrazolinecarboxylic Acids. CARL BÜLOW (*Ber.*, 1912, **45**, 3349—3355).—A reply to Darapsky's criticism (A., 1912, i, 391) of the author's view that the additive products of ethyl diazoacetate with olefinic esters are really open-chain compounds (A., 1912, i, 134, 316). D. F. T.

Condensation Product of Formaldehyde, Ammonia, and Antipyrine. CARL MANNICH and W. KRÖSCHE (*Arch. Pharm.*, 1912, 250, 647—667).—Antipyrine condenses with formaldehyde and ammonia, or with the hexamethylenetetramine formed from these two substances, to give triantipyryltrimethyleneamine,

$$N(CH_2 \cdot O \cdot C_{11}H_{11}N_2)_3,$$
in the formation of which antipyrine is believed to react in the enolic form represented by the formula $NPh\begin{smallmatrix}C(OH)\colon C\\ | \quad | \\ NMe{-}CMe\end{smallmatrix}$. A similar condensation occurs with antipyrine derivatives so long as these are not substituted in position 4.

Triantipyryltrimethyleneamine hydrochloride, $C_{36}H_{40}O_3N_7Cl,6H_2O$, m. p. 178°, or 206° (dry), formed when the condensation is effected by hydrochloric acid, is crystalline. The free base, m. p. 259—260°, crystallises anhydrous from methyl alcohol. When boiled with hydrochloric acid, it yields formaldehyde, ammonia, and methylenebisantipyrine, which yields a trihydrated dihydrochloride (Schuftan, A., 1895, i, 482), and a *monohydrochloride*, $CH_2(C_{11}H_{11}ON)_2,HCl,3H_2O$, m. p. 94—95°, which on drying at atmospheric temperature over sulphuric acid becomes *anhydrous*, then melts at 100—110°, and on solution in acetone deposits some *anhydrous dihydrochloride*, m. p. 200—220°, leaving some free base in solution.

On treatment with sodium hydrogen sulphite and sulphurous acid, triantipyryltrimethyleneamine yields antipyrine, which appears to be formed direct from the parent substance, since sulphurous acid has no action on methylenebisantipyrine.

Tritolypyryltrimethyleneamine, $C_{39}H_{45}O_3N_7,7H_2O$, m. p. 214—215° (dry), formed by condensing hexamethylenetetramine with tolypyrine (p-tolyl-2 : 3-dimethyl-5-pyrazolone), crystallises from a mixture of methyl alcohol and water; the *hydrochloride*, $C_{39}H_{40}O_3N_7Cl,6H_2O$, m. p. 100—105°, or 191° (dry), forms short, stout needles. Sulphurous acid in presence of sodium hydrogen sulphite hydrolyses it to tolypyrine, whilst hydrochloric acid converts it into ammonia, formaldehyde, and *methylenebistolypyrine*, m. p. 183—186°, or 190° (dry), which crystallises from 80% alcohol in slender needles, and can be prepared by condensing tolypyrine with formaldehyde.

Trihomoantipyryltrimethyleneamine, m. p. 280°, similarly obtained, crystallises from boiling methyl alcohol ; the *hydrochloride,* m. p. 202°, crystallises from acetone. *Methylenebishomoantipyrine* crystallises from ethyl acetate in tablets with $1H_2O$, m. p. 120—130°, and after drying over sulphuric acid melts at 105—106°. The *dihydrochloride,*

$$C_{25}H_{30}O_2N_4Cl_2,3H_2O,$$
separates from 10% hydrochloric acid in stout crystals, m. p. 200—210°.

T. A. H.

Substituted α-Hydroxy- and α-Methyl-benziminazoles. OTTO KYM and L. RATNER *(Ber.,* 1912, **45,** 3238—3255. Compare A., 1904, i, 453 ; 1911, i, 1044).—*p*-Nitro-*o*-phenylenediamine reacts readily with carbamide, forming 5-nitro-2-hydroxybenziminazole,

$$NO_2 \cdot C_6H_3 {\overset{NH}{\underset{N}{\big<}}} C \cdot OH$$
(compare Hager, A., 1885, 149). This reacts with phosphoryl chloride forming 2-chlorobenziminazole, from which the 2-hydroxy-compound is regenerated on boiling with concentrated hydrochloric acid. Ammonia or aniline converts it into corresponding 2-amino- or 2-anilino-derivatives. The property of the azo-dyes of all phenylated benziminazoles to dye cotton persists, although to a less degree, in the 2-hydroxy-compounds.

Both 2-hydroxyl- and 2-methyl-benziminazoles can be nitrated without difficulty, forming dinitro-derivatives. It was found impossible to open the iminazole ring in these by Bamberger's method—by means of benzoyl chloride and sodium hydroxide.

Dinitro-2-hydroxybenziminazole when heated with aniline yields nitro-2-hydroxyanilinobenziminazole,

$$NHPh \cdot C_6H_2(NO_2) {\overset{NH}{\underset{N}{\big<}}} C \cdot OH,$$
a red, crystalline compound, whereas the mononitro-2-hydroxybenziminazole does not react with aniline. This behaviour indicates that the second nitro-group has entered in the ortho-position to the first.

On reduction of the dinitro-compounds the diamino-compounds obtained behave as *o*-diamines, forming azimino-derivatives with nitrous acid and the corresponding dianhydro-derivatives when boiled with acetic acid. 2 : 7-Dimethylbenzdi-iminazole,

$$CMe {\overset{NH}{\underset{N}{\big>}}} C_6H_2 {\overset{NH}{\underset{N}{\big<}}} CMe,$$
is shown to be identical with Nietzki's (A., 1887, 476, 477) diethenyl base obtained by nitration and reduction of diacetyl-*m*-phenylenediamine.

When 5 : 6-diamino-2-methylbenziminazole is fused with carbamide the dihydro-derivative already mentioned, 7-hydroxy-2-methylbenzdi-iminazole, $CMe {\overset{NH}{\underset{N}{\big>}}} C_6H_2 {\overset{NH}{\underset{N}{\big<}}} C \cdot OH$, is formed. These changes confirm the structure of dinitro-2-hydroxybenziminazole as

$$\overset{NO_2}{\underset{NO_2}{}} {\Large\bigcirc} {\overset{-NH}{\underset{-NH}{\big>}}} C \cdot OH.$$
5-Nitro-2-hydroxybenziminazole crystallises in yellowish-white needles,

m. p. 308°; it is strongly acid, dissolving in alkali hydroxide with an intense orange-yellow coloration. It further has weak basic properties.

5 : 6-*Dinitro-2-hydroxybenziminazole* separates in centimetre-long, lustrous needles, m. p. above 300°; the solution in cold dilute alkali hydroxide is intense red, and it forms a deep red, crystalline sodium salt.

5 : 6-*Dinitro-2-methylbenziminazole* forms yellowish-white needles, m. p. 223°.

Nitro-2-hydroxyanilinobenziminazole crystallises in red platelets, m. p. 298°.

Nitroamino-2-hydroxybenziminazole, prepared by heating the dinitro-compound with ammonia at 180—210°, forms bright red, lustrous crystals, m. p. above 300°; it is soluble in concentrated hydrochloric acid, and also dissolves in dilute sodium hydroxide or ammonia with a deep red coloration.

5 : 6-*Diamino-2-hydroxybenziminazole* readily oxidises as free base ; the *hydrochloride* forms a brown, microcrystalline powder ; the *diacetyl* derivative crystallises in lustrous, silky needles, m. p. 293—294° ;

2-*hydroxybenzdi-iminazole*, $N<^{NH}_{N}>C_6H_2<^{NH}_{N}>C\cdot OH$, crystallises in yellow platelets, m. p. above 300°.

5 : 6-*Diamino-2-methylbenziminazole* crystallises in pale brown needles, m. p. above 300°; the *diacetyl* derivative separates in slightly pink-coloured, glistening needles, also m. p. above 300°. 2-*Methylbenzdi-iminazole* forms reddish-brown, stunted needles, m. p. above 300°.

2 : 7-*Dimethylbenzdi-iminazole* is obtained in lustrous, yellowish-white needles, m. p. outside the thermometer range.

7-*Hydroxy-2-methylbenzdi-iminazole* also forms lustrous, yellowish-white platelets, m. p. above 300°.

2-*Chloro-5-nitrobenziminazole* is a yellow, crystalline powder, m. p. 222—223°.

5-*Nitro-2-anilinobenziminazole* yields tiny, brown crystals, m. p. 278°.

5-*Nitro-2-aminobenziminazole* crystallises in a bulky mass of slender, yellow needles, m. p. 189—190°; the *acetyl* derivative is colourless.

E. F. A.

Constitution of Compounds from o-Diamines and α-Hydroxy-acids. Acetylation of Benziminazoles. AUGUSTIN BISTRZYCKI and GEORG PRZEWORSKI (*Ber.*, 1912, **45**, 3483—3495).—The product obtained by the interaction of 3 : 4-tolylenediamine and lactic acid is regarded as a tetrahydroquinoxaline by Georgescu, and as a benzimin-azole by Hinsberg. The authors now show that the latter view is correct and that the reaction is a general one ; thus o-phenylenediamine and mandelic acid (1¼ mol.) at 130—135° yield 2-α-hydroxybenzyl-benziminazole ; o-phenylenediamine and lactic acid (3 mols.) at 105—110° yield 2-α-hydroxyethylbenziminazole ; 3 : 4-tolylenediamine and mandelic acid (1¼ mol.) at 130—135° yield 2-α-hydroxybenzyl-5-methylbenziminazole, and 3 : 4-tolylenediamine and lactic acid yield 5-methyl-2-α-hydroxyethylbenziminazole. These substances are identical with Georgescu's so-called tetrahydroquinoxalones.

o-Phenylenediamine and glycollic acid at 120° yield 2-*hydroxymethyl-*

benziminazole, $C_6H_4<^{NH}_{N}>C\cdot CH_2\cdot OH$, m. p. 171—172°, colourless plates, which forms an *acetyl* derivative, m. p. 99—101°, by boiling with acetic anhydride and sodium acetate, and is oxidised by hot dilute alkaline potassium permanganate to *benziminazole-2-carboxylic acid*,

$$C_8H_6O_2N_2, 2H_2O,$$

decomp. 169°, long prisms (*barium* salt, $C_{16}H_{10}O_4N_4Ba$), from which benziminazole is obtained by heating at 169°. The authors find that benziminazoles are readily acetylated by heating with acetic anhydride; thus benziminazole or benziminazole-2-carboxylic acid yields 1-*acetylbenziminazole*. m. p. 113—114°, long, prismatic needles, and 2-methylbenziminazole yields 1-*acetyl-2-methylbenziminazole*, m. p. 85—86°, colourless, microscopic needles or prisms.

3 : 4-Tolylenediamine and glycollic acid yield 5-*methyl-2-hydroxymethylbenziminazole*, m. p. 203°, plates or needles (*acetyl* derivative, m. p. 129—132°), from which Hinsberg's 5-methylbenziminazole-2-carboxylic acid, m. p. 156° (decomp.), is obtained by oxidation.

By oxidation with chromic and acetic acids, 2-α-hydroxybenzylbenziminazole yields 2-*benzoylbenziminazole*, $C_6H_4<^{NH}_{N}>C\cdot COPh$, m. p. 209—210° (decomp.), microscopic needles (*phenylhydrazone*, m. p. 185—186°, yellow plates; *phenylmethylhydrazone*, m. p. 225°, yellow prisms), and 2-α-hydroxybenzyl-5-methylbenziminazole yields 2-*benzoyl-5-methylbenziminazole*, m. p. 140—141°, felted needles.

Equal molecular quantities of *o*-phenylenediamine and benzilic acid at 150—160°, or *o*-phenylenediamine (1·5 mol.) and chlorodiphenylacetic acid under the same conditions, yield a *substance*, $C_{20}H_{16}ON_2$, m. p. 221—223°, microscopic plates, which is probably 2-*hydroxydiphenylmethylbenziminazole*, $C_6H_4<^{NH}_{N}>C\cdot CPh_2\cdot OH$. The 5-methyl *homologue*, m. p. about 255°, is obtained from 3 : 4-tolylenediamine and chlorodiphenylacetic acid, whilst diphenylacetic acid and *o*-phenylenediamine yield 2-*benzhydrylbenziminazole*, $C_6H_4<^{NH}_{N}>C\cdot CHPh_2$, m. p. 218—220°, colourless, prismatic needles.   C. S.

The Constitution of Acetyl-β-anthraquinonylmethylpyrazolone. RICHARD MÖHLAU (*Ber.*, 1912, **45**, 3596).—The pyrazolone described recently (Möhlau, A., 1912, i, 704) is 4-acetyl-1-β-anthraquinonyl-3-methylpyrazolone.   D. F. T.

Preparation of Nitrogenous Condensation Products of the Anthraquinone Series. ALFRED SCHAARSCHMIDT (D.R.-P. 251480). —When *o*-diaminoanthraquinones are condensed with benzanthrone or anthraquinone, ω-di- or ·ω-tri-halogenmethyl derivatives, aldehydes, carboxylic acids, or their chlorides, they furnish iminazole condensation derivatives.

Compounds from the condensation of 1 : 2-diaminoanthraquinone with anthraquinone-2-carboxylic acid and with *benzanthronecarboxylic acid* (a yellow powder obtained from *p*-tolyl-*o*-benzoic acid, glycerol, and sulphuric acid), and from 2 : 3-diaminoanthraquinone with ω-dichloro-β-methylanthraquinone are described.   F. M. G. M.

Preparation of Anthraquinone Derivatives containing Nitrogen. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252529).—The action of aldehydes on aryl-*o*-aminoanthraquinones has previously been described (A., 1907, i, 1085) ; when these are replaced by ketones the following action occurs :

$$A{<}^{\text{NHPh}}_{\text{NH}_2} + R{\cdot}CO{\cdot}R' = A{<}^{\text{NH}-}_{\text{N}-} \bigcirc + H_2O,$$
$$R{\cdot}CHR'$$
where A = anthraquinone, and R' and R aryl or alkyl.

3-Bromo-2-amino-1-*p*-toluidinoanthraquinone (10 parts) when boiled with acetone (10 parts), zinc chloride (5 parts), and acetic acid (100 parts) yields a *compound*, bluish-red needles with metallic lustre ; whilst *compounds* from the same base with acetophenone, and with isatin (blue needles), and from 3 : 7-dibromo-2 : 6-diamino-1 : 5-dianilinoanthraquinone with acetone are described in the original. These compounds all furnish soluble *sulphonic acids*, which dye wool in blue shades. F. M. G. M.

[**Preparation of Anthracene Derivatives.**] FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 251021).—When the dyes obtained from di- and tri-anthrimides by the action of aluminium chloride are treated (in a paste) with sodium hypochlorite at 80° new compounds are formed.

$$C_6H_4{<}^{\text{CO}-}_{\text{CO}-} \bigcirc {-}N{\cdot}C_{14}H_7O_2$$
$$C_{14}H_7O_2{\cdot}N{-} \bigcirc {<}^{\text{CO}}_{\text{CO}}{>}C_6H_4$$
Dianthraquinonylindanthren, $C_{56}H_{26}O_8N_2$ (annexed formula), orange-yellow needles, which decomposes at high temperatures with partial sublimation, is thus obtained from the product furnished by *aa*-dianthrimide ; whilst the dye from 1 : 5-di-*a* : *a*-anthriminoanthraquinone and aluminium chloride yields under similar conditions a *compound* consisting of a reddish-brown powder. F. M. G. M.

Indamines. FRITZ ULLMANN and JOHANN GNAEDINGER (*Ber.*, 1912, **45**, 3437—3446).—Indamines are readily obtained by passing air through a cold dilute aqueous solution of equal molecular quantities of a meta-diamine and *p*-aminophenol hydrochloride after the addition of dilute sodium hydroxide (2 mols.) ; thus *m*-tolylenediamine and *p*-aminophenol yield 2-*amino-4'-hydroxy-5-methylindamine,*

$$NH{:}C_6H_2Me(NH_2){:}N{\cdot}C_6H_4{\cdot}OH,$$
decomp. about 165°, green metallic needles containing $3H_2O$. It is readily soluble in aqueous sodium hydroxide, and by reduction with alkaline sodium hyposulphite yields 2 : 4-*diamino-4'-hydroxy-5-methyldiphenylamine,* $C_6H_3Me(NH_2)_2{\cdot}NH{\cdot}C_6H_4{\cdot}OH$, m. p. 215°, colourless crystals (*sulphate,* $C_{18}H_{15}ON_3,H_2SO_4$, m. p. 202°). By the prolonged passing of air through its suspension in hot water, the indamine is converted into the *phenazine,* $NH_2{\cdot}C_6H_2Me{<}^{\text{N}}_{\text{N}}{>}C_6H_3{\cdot}OH$, m. p.

above 360°, red needles with green reflex (*hydrochloride*, m. p. above 360°, red needles with green reflex; *diacetyl* derivative, m. p. 291°, darkening at 282°, yellow crystals).

m-Phenylenediamine and *p*-aminophenol yield Nietzki's so-called aminoindophenol, which, however, on account of its solubility in sodium hydroxide, is more suitably regarded as the hydroxyindamine, $NH:C_6H_3(NH_2):N\cdot C_6H_4\cdot OH$. The phenazine obtained by its further oxidation has m. p. above 360°, not 268° as given by Nietzki; also the diacetyl derivative has m. p. 275°, not 258°.

3'-Chloro-2-amino-4'-hydroxy-5-methylindamine,
$$NH:C_6H_2Me(NH_2):N\cdot C_6H_3Cl\cdot OH,$$
m. p. 185°, metallic violet needles containing H_2O, obtained from *m*-tolylenediamine and 2-chloro-*p*-aminophenol, yields *3'-chloro-2 : 4-diamino-4'-hydroxy-5-methyldiphenylamine*, m. p. 212°, colourless needles, by reduction, and the *phenazine*, $C_{13}H_{10}ON_3Cl$, m. p. above 360° (*diacetyl* derivative, m. p. 274°), by oxidation.

6-Chloro-*m*-phenylenediamine and *p*-aminophenol yield the *indamine*, $NH:C_6H_2Cl(NH_2):N\cdot C_6H_4\cdot OH$, decomp. 108°, metallic violet crystals containing H_2O (the corresponding *phenazine* and its *diacetyl* derivative have m. p. above 360° and 307° respectively), whilst 6-chloro-*m*-phenylenediamine and 2-chloro-*p*-aminophenol yield the *indamine*,
$$NH:C_6H_2Cl(NH_2):N\cdot C_6H_3Cl\cdot OH,$$
decomp. 128°, metallic violet needles containing H_2O.

By a similar process of oxidation, α-naphthol and *p*-aminophenol yield the *dihydroxyindonaphthol*, $OH\cdot C_6H_4\cdot N:C\underset{:CH:C(OH)}{\overset{C_6H_4}{<}}>CO$, m. p. 298°, glistening, green leaflets changing to a red powder at 120°. This substance, the constitution of which is proved by its formation from potassium β-naphthaquinone-4-sulphonate and *p*-aminophenol hydrochloride in cold aqueous solution, condenses with *o* phenylenediamine in alcoholic solution to form the *hydroxyanilinonaphthazine*,
$$OH\cdot C_6H_4\cdot NH\cdot C_{10}H_5\underset{N}{\overset{N}{<}}>C_6H_4,$$
m. p. 291°, orange crystals.   C. S.
Synthesis of 1 : 3 : 7-Naphtha*iso*triazines : Derivatives of a New Heterocyclic System. MARSTON T. BOGERT and HARRY LINN FISHER (*J. Amer. Chem. Soc.*, 1912, **34**, 1576—1580).—In another paper (this vol., i, 98) the authors have described 5-aminoquinoline-6-carboxylic acid, its acetyl derivative, and the lactam of the latter. From these substances, compounds have been prepared containing the new nucleus (annexed formula), which is designated the 1 : 3 : 7-naphtha*iso*triazine nucleus.

2 : 3-*Dihydro*-1 : 3 : 7-*naphthaisotriazine*-4-*one* (4-*hydroxy*-1 : 3 : 7-*naphthaisotriazine*),
$$\underset{-NH\cdot CO}{\overset{CH=N}{>}}C_9NH_5 \rightleftharpoons \underset{N:C(OH)}{\overset{CH=N}{>}}C_9NH_5,$$
m. p. 298·7° (corr.), obtained in 10% yield by heating 5-aminoquinoline-6-carboxylic acid with excess of formamide at 140° in
a sealed tube, crystallises in lustrous, pink prisms. The *2-methyl* derivative, m. p. above 300° (decomp.), prepared by boiling the lactam of 5-acetylaminoquinoline-6-carboxylic acid with solution of ammonia, forms slender, yellow needles, and, when heated with benzaldehyde and a few drops of acetic anhydride, yields the *2-styryl* derivative, $CHPh:CH \cdot C_{11}H_6ON_3$, m. p. above 300° (decomp.), as a yellow, crystalline powder. The 2 : 3-*dimethyl* derivative,

$$\begin{matrix} CMe = N \\ NMe \cdot CO \end{matrix} > C_9NH_5,$$
m. p. 178° (uncorr.), prepared by the action of methylamine on the lactam, crystallises in long, yellow needles. The *2-methyl-3-ethyl*, *2-methyl-3-n-propyl*, *3-phenyl-2-methyl*, and *3-p-anisyl-2-methyl* derivatives have m. p. 152·5° (uncorr.), 121—122° (uncorr.), 263—263·5° (corr.), and 246·9—247·9° (corr.) respectively. The *3-amino-2-methyl* derivative, m. p. 256·7° (corr.), obtained by the action of hydrazine on the lactam, is colourless; the *3-acetylamino-2-methyl* derivative has m. p. 268·5—269·5° (corr.), and the *3-benzylideneamino-2-methyl* derivative, m. p. 222·6° (corr.). The *3-anilino-2-methyl* derivative, $\begin{matrix} CMe = N \\ N(NHPh) \cdot CO \end{matrix} > C_9NH_5$, m. p. 249·5—250·5° (corr.), crystallises in pale brown needles.

1 : 2 : 3 : 4-*Tetrahydro*-1 : 3 : 7-*naphthaisotriazine*-2 : 4 -*dione*   (2 : 4-*dihydroxy*-1 : 3 : 7-*naphthaisotriazine*),

$$\begin{matrix} CO \cdot NH \\ NH \cdot CO \end{matrix} > C_9NH_5 \rightleftharpoons \begin{matrix} C(OH):N \\ N:C(OH) \end{matrix} > C_9NH_5,$$
m. p. above 300°, is obtained as a yellow or brown powder by fusing a mixture of 5-aminoquinoline-6-carboxylic acid and carbamide.

E. G.

[**Preparation of Anthracene Derivatives.**] CHEMISCHE FABRIK GRIESHEIM-ELEKTRON (D.R.-P. 253088).—It is found that the previously described ψ-azimino-compounds (A., 1912, i, 1035) obtained by oxidising the azo-compound formed by coupling 2-aminoanthracene with diazotised 2-aminoanthraquinone can be nitrated, and the so-obtained *nitro-* or *dinitro-*compounds reduced with sodium sulphide or alkaline sodium hyposulphite to the corresponding *amino-* or *diamino-*compounds. The nitrated products are greenish-yellow, and the amino-derivatives, brownish-black, powders.

F. M. G. M.

Methyliminothiotriazine. ADRIANO OSTROGOVICH (*Chem. Zentr.*, 1912, ii, 607 ; from *Bull. Soc. Şti. Bucureşti*, 1912, 21, 27—31).—The 2-imino-6-thiol-4-methyl-1 : 3 : 5-triazine, already described (A., 1912, i, 320), on oxidation with nitric acid (D 1·4) yields cyanuric acid, and with alkaline permanganate gives iminoketomethyltriazine (A., 1904, i, 832), the picrate of which melts at 221—221·5°, not 121—121·5° as stated previously. Iminothiolmethyltriazine does not give up its sulphur to mercuric oxide, but yields a stable mercury salt when mercuric chloride is added to its solutions in aqueous sodium hydroxide.

T. A. H.

Quadriurates. WILLEM E. RINGER and J. I. J. M. SCHMUTZER (*Zeitsch. physiol. Chem.*, 1912, 82, 209—220. Compare Kohler, A., 1911, i, 243, 690).—The hypothesis that the so-called quadriurates are mixed crystals has been tested experimentally, a series of quadriurates of varying composition having been examined chemically and crystallographically. This hypothesis is satisfactory when it is assumed that the urates represent solid solutions of uric acid in ordinary mono-metal urates, which are formed at high temperatures, but are unstable at lower temperatures, and tend to part with the excess of uric acid.

E. F. A.

Preparation of Aminobenzoylamino-compounds FARBEN-FABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 252376) —When sodium diaminobenzoyldiaminostilbenedisulphonate is fused during half an hour with *p*-nitrobenzoyl chloride and the *di*-p-*nitrobenzoyl* derivative subsequently reduced with iron and acetic acid, it furnishes the compound, $C_2H_2[C_6H_8(SO_3Na)\cdot NH\cdot CO\cdot C_6H_4\cdot NH\cdot CO\cdot C_6H_4\cdot NH_2]_2$.

Other analogous compounds with valuable tinctorial properties can be obtained in the benzidine, tolidine, or dianisidine series.

F. M. G. M.

Separation of Proteoses by Ultra-filtration. EDGARD ZUNZ (*Bull. Acad. roy. Belg.*, 1912, 656—674. Compare A., 1911, i, 1050). —The composition of the filtrate obtained from identical solutions of Witte's peptone, submitted under the same conditions to Bechhold's method of ultra-filtration, varies appreciably from filter to filter, although the latter are made as alike as possible. Further, the filtrate varies during the course of the same experiment, at one time the ultra-filter allowing certain proteoses to pass and at another time retaining a portion of them. The four groups of proteoses established by Pick cannot be satisfactorily separated by successively employing ultra-filters with smaller and smaller pores. The ultra-filtration causes a dissociation of each of these groups of proteoses into several fractions. In these groups the proteoses, the aliphatic amino-nitrogen of which can be detected by van Slyke's method, pass completely through an ultra-filter made by means of a 6% collodion solution.   W. G.

Changes in the Physical Conditions of Colloids. XIV. The Hydration of Various Protein Compounds, with Special Reference to the Action of Caffeine. WOLFGANG PAULI and OSKAR FALEK (*Biochem. Zeitsch.*, 1912, 47, 270—299).—The general theory of Pauli's as to the high degree of hydration of the protein ion is confirmed by a series of measurements of the changes of viscosity of well dialysed gelatin solutions on addition of acids and alkalis, in both of which cases well-marked maxima are observed. According to the theory, salts combine with the protein, and when these are present, the number of free proteins ions is diminished. The addition of salts diminishes the viscosity, and this effect was quantitatively measured in the case of several salts.

Caffeine has, however, a peculiar action on the ox- and horse-serum proteins, in that it increases the viscosity of the acid-protein mixtures

(and according to Pauli the state of hydration in solution). This effect has been measured in a large number of cases. The magnitude of the effect is also influenced by the nature of the acid employed. A similar effect was produced by theophylline, but not by diethylglycin-amine caffeine or caffeine ethylenediamine, both of which produce a depression of viscosity. Caffeine does not effect the hydration of gelatin or fibrin, as it does not cause these substances to take up more water. The reason of the peculiar action of caffeine on certain proteins may be due to formation of complex double compounds. It does not appear to be due to direct salt formation, as determined by the effect of addition of caffeine to protein solutions on the electro-lytic conductivities, the osmotic pressures, or the hydrogen-ion concen-trations as measured by the electrometric method. S. B. S.

The Oxidation Relations of Certain Heavy Metals in Com-bination with Protein, and Some Physico-chemical Properties of the Same. II. CARLO CERVELLO and CORRADO VARVARO (*Arch. expt. Path. Pharm.*, 1912, 70, 369—374).—The coagulation rate of zinc albuminate and mercury albuminate is greater than that of the simple protein, but less than that of the albuminates of manganese and copper. Iron albuminate is not altered by boiling. Complete coagulation with precipitation of denaturated protein is only obtained with zinc albuminate. In weakly acid or neutral solutions, the other metallic albuminates give only a cloudy fluid on heating : this is most marked with mercury, and least with manganese albuminate. In reference to their oxidative powers, as measured by the effect on indigotin and similar substances, the albuminates of iron and copper are most energetic ; those of mercury, zinc, and manganese follow in the order named. The albuminates therefore behave like simple metallic salts. W. D. H.

The Kyrine Fraction obtained on Partial Hydrolysis of Proteins. I. PHŒBUS A. LEVENE and F. J. BIRCHARD (*J. Biol. Chem.*, 1912, 13, 277—289).—Siegfried's hypothesis regarding kyrine is that it is a fragment of the protein molecule which resembles natural protamines. The kyrine fraction obtained in the present research by Siegfried's method of partial hydrolysis of gelatin yielded on hydrolysis arginine, lysine, glutamic acid, glycine, and proline in peptide linking. Probably two peptides were present, one con-taining lysine and three monoamino-acids, and the other, arginine and one monoamino-acid. Further investigations are being prosecuted. W. D. H.

The Isoelectric Point of Casein. LEONOR MICHAELIS and H. PECHSTEIN (*Biochem. Zeitsch.*, 1912, 47, 260—268).—The isoelectric point was determined by ascertaining the optimal mixture for precipi-tation of sodium acetate and acetic acid solutions, and also by the method of electrocataphoresis. In the former case the salt concen-trations in the various series of experiments were kept constant, and in the latter case, the salt content was kept very low. By these methods the isoelectric point was found to be $2·5 \times 10^{-5}$ and $2·4 \times 10^{-5}$.

respectively. In the presence of salts a certain asymmetry of behaviour was observed, in that after twenty-four hours excess of acid above the isoelectric point allowed greater precipitation than deficit of acid.

S. B. S.

Blood Pigment. LÉON MARCHLEWSKI (*Zeitsch. physiol. Chem.*, 1912, 82, 413—414. Compare Grabowski and Marchlewski, A., 1912, i, 1015).—The conclusion that hæmopyrrole whether derived from blood pigment or chlorophyll contains 3-methyl-4-ethylpyrrole is confirmed by Piloty and Stock (A., 1912, i, 923), who obtain the same substance from hæmin. The synthesis of chlorophyll in plants begins probably with that of 3-methyl-4-ethylpyrrole.   E. F. A.

Nomenclature of Derivatives of the Blood Pigment. KARL BURKER (*Zeitsch. physiol. Chem.*, 1912, 82, 346).—Instead of Abderhalden's (A., 1912, i, 521) nomenclature of hæmatin for hæmochromogen and oxyhæmatin for hæmatin, it is suggested to use the terms reduced hæmatin and oxyhæmatin.   E. F. A.

Methylation of Hæmin. IV. WILLIAM KUSTER (*Zeitsch physiol Chem.*, 1912, 82, 113—159).—In the preparation of hæmin by Mörner's method using methyl alcohol, a crude product is obtained in satisfactory amount containing very little protein, which usually consists mostly of methylhæmin mixed with a little dimethylhæmin. There is evidence that there are two methylhæmins, one or the other being formed from ox-blood according to the conditions. One isomeride is insoluble in 5% sodium carbonate; the other is soluble in sodium carbonate, and also in 0·7% potassium carbonate. The dissolved dye contains chlorine.

The first isomeride loses chlorine without dissolving, and forms a methylhæmatin; a similar compound is formed by the action of methyl-alcoholic sodium hydroxide.

The dehydrochloride products prepared from the methylhæmins are of different composition, the one being normal, the other having taken up a molecule of water.

Methylhæmatin and hæmatin when dissolved in methyl alcohol containing sulphuric acid and the boiling solution precipitated by hydrochloric acid yield dimethylated products which do not contain the calculated proportion of chlorine for hæmin derivatives and are soluble in acidified methyl alcohol. Dehydrochloromethylhæmin under similar treatment does not show a complete addition of hydrogen chloride.

Dehydrochlorohæmin is converted into dimethylhæmin. Dimethylhæmin forms a dimethylated dehydrochloro-product.

Methylhæmin is hydrolysed by more than three molecules of 1% sodium hydroxide in the cold; dimethylhæmin requires warming to effect hydrolysis. Dimethylhæmin is readily converted into dimethylhæmatin by the action of methyl alcoholic sodium hydroxide.

E. F. A.

Preparation of Hæmatoporphyrin from Carbon Monoxide Blood. VINZENZ ARNOLD (*Zeitsch. physiol. Chem.*, 1912, 82, 273—275). —Pure hæmatoporphyrin, particularly suited for spectroscopic work and free from brown-coloured impurities, is obtained by completely replacing the oxygen in blood by carbon monoxide before acting on it with sulphuric acid.   E. F. A.

Formation of Porphyrin. HANS FISCHER and FRIEDRICH MEYER-BETZ (*Zeitsch. physiol. Chem.*, 1912, 82, 96—108).—The exact conditions for the preparation of mesoporphyrin are described. On oxidation with lead peroxide in acid solution, methylethylmaleinimide,

$$NH\!\!<\!\!{}^{CO \cdot CEt}_{CO \cdot CMe},$$
and hæmatic acid, $NH\!\!<\!\!{}^{CO \cdot CMe}_{CO \cdot C \cdot CH_2 \cdot CH_2 \cdot CO_2H}$, are obtained. On reduction by means of hydrogen iodide in acetic acid and phosphonium iodide, the same products were obtained as are given by hæmin, including hæmopyrrole and phonopyrrolecarboxylic acid. Mesoporphyrin is considered to be a simple reduction product of hæmin minus its iron. Possibly the porphyrin spectrum is due to the elimination of the complex iron grouping from hæmin; in fact, the complex iron salt of porphyrin shows the hæmin spectrum. It is probable that two alcoholic hydroxyl groups are reduced in the formation of mesoporphyrin.

Pure mesoporphyrin has no poisonous photobiological action, whereas hæmatoporphyrin when injected subcutaneously into mice which are exposed to light causes death.   E. F. A.

[**Guanylic Acid.**] IVAR BANG (*Biochem. Zeitsch.*, 1912, 46, 500—501).—The author believes that the guanylic acid recently isolated in the form of a crystalline brucine salt by Levene and Jacobs (A., 1912, i, 926) is not guanylic acid itself, but a scission product.
                                                                   S. B. S.

The Pentose of Guanylic Acid. KG. O. AF KLERCKER (*Biochem. Zeitsch.*, 1912, 47, 331—342).—The author gives a general view of the literature concerning the sugar derived from the pancreatic nucleic acid, guanylic acid, and allied substances. He prepared the osazone from guanylic acid, and obtained rotations of -0.59 to $-0.64°$ for 0.2 gram in 10 c.c. for various preparations recrystallised from alcohol. For *l*-arabinose preparations obtained in the same way he obtained numbers from $+0.62$ to $0.69°$, and for *l*-xylose preparations -0.67 and $0.70°$. The sugar from which the guanylic acid pentosazone was prepared was lævorotatory, and as xyloses yield osazones which rotate in the opposite direction to the sugars themselves, the conclusion is drawn that the guanylic acid pentose is not *l*-xylose, but probably belongs to the *d*-arabinose group. The conclusion is also supported by the general character of the osazones as regards behaviour on crystallisation and appearance. Nevertheless, the author states that the optical properties of the phenylpentosazones do not

form a satisfactory criterion for distinguishing between the various sugars.   S. B. S.

The Optimal Hydrogen-ion Concentration for the Liquefaction of Gelatin by Trypsin. SVEN PALITZSCH and L. E. WALBUM (*Biochem. Zeitsch.*, 1912, 47, 1—35).—Fermi's method was employed, but was modified in two particulars, in that, firstly, boracic acid was added to the gelatin to avoid change of hydrogen-ion concentration during the digestion, and, secondly, the digestion mixture was neutralised after completion of the action of trypsin, so that the actual cooling process took place at the same hydrogen-ion concentration, for it was found that solutions of undigested gelatin solidified more slowly in alkaline than in neutral solutions in the absence of boric acid, although there was not much difference when this acid was present. By means of this method it was found that the optimal conditions for liquefaction were at the following hydrogen-ion concentrations : at 30°, $10^{-9\cdot9}$; at 37°, $10^{-9\cdot7}$; at 45°, $10^{-9\cdot1}$; at 55°, $10^{-8\cdot0}$; that is to say, the higher the temperature, the nearer to the neutral point is the hydrogen-ion concentration for tryptic activity when measured by the Fermi process.   S. B. S.

The Mechanism of Pepsin Digestion. JOHANNE CHRISTIANSEN (*Biochem. Zeitsch.*, 1912, 47, 226—249).—The viscometric method was adopted, and in the preliminary experiments on the action of acid on genuine proteins (dialysed serum proteins, etc.), it was found that the addition of acid increased the viscosity of the solutions up to a certain maximum point, after which further additions caused a diminution. The Günzburg reaction for hydrochloric acid becomes positive at the point of maximal viscosity, thus bearing out Pauli's theory that at this point the solution contains essentially chlorine ions and heavily hydrated protein ions. The viscosity is diminished by filtration through paper, more especially when only just sufficient acid is present to produce the maximum readings. With larger excess of acid, the effect of filtration becomes less marked. Similar results were obtained on filtration of mixtures of protein and alkali, and the results indicate that the protein ion is adsorbed by the paper. In investigating the action of pepsin, viscosity changes of mixtures having the same initial viscosity but different amounts of acid (that is, amounts of acid less and more than necessary to produce a mixture with the maximum viscosity) were chosen. It was found that such corresponding mixtures, under the influence of pepsin, changed their viscosities at the same rate, which fact seems to indicate that in the neighbourhood of maximal viscosity the rate of pepsin action is independent of the hydrogen-ion concentration. This result is not in accordance with results obtained with coagulated egg-white, which requires a certain excess of acid for maximal digestion rate. The difference is ascribed to the change in the character of the protein. Preliminary experiments carried out with dialysed sheep serum-albumin, in which the rate of formation of acid albumin was ascertained (this is only formed in this case when pepsin is present as well as acid), also indicated that the maximum rate of formation of this product takes place at the

point of maximum viscosity (that is, when there are the maximum number of protein ions present). S. B. S.

The Enzymes of the Pancreas. I. The Generation of Trypsin from Trypsinogen by Enterokinase. JOHN MELLANBY and V. J. WOOLLEY (*J. Physiol.*, 1912, 45, 370—388).—The time occupied in activating trypsinogen by enterokinase is a function of the amount of the latter enzyme added. As the action proceeds, trypsin is produced at a constantly increasing rate. The reaction is accelerated by rise of temperature ; it occurs best in a neutral medium, is delayed by alkali, and stopped by acid. There is no evidence that trypsin can activate trypsinogen, or that trypsin acts as a co-enzyme to enterokinase. Proteins apparently delay activation, because the trypsin first formed is adsorbed by the protein ; the delay varies in different proteins. The following theory is advanced : Enterokinase is a proteolytic enzyme acting best in a neutral medium ; trypsinogen contains a protein moiety with which trypsin is combined, and in this combination the proteolytic properties of trypsin are masked. The generation of trypsin from trypsinogen by enterokinase depends on the adsorption of the enterokinase by the protein moiety of the trypsinogen ; digestion of the protein moiety follows, and trypsin is thus liberated. W. D. H.

Action of Hydrogen Chloride on Invertase. II. THEODOR PANZER (*Zeitsch. physiol. Chem.*, 1912, 82, 377—390. Compare following abstract).—Purified invertase takes up considerable quantities of hydrogen chloride, losing its specific activity. The greater part of the hydrogen chloride is removed on keeping in a vacuum, but the hydrolytic activity is not regained.

The invertase preparation contained 5·57% of nitrogen, 2·3% being amide nitrogen and 3·17% titratable in presence of formaldehyde. The ash amounted to 22·2% ; the acidity was five to six times as large as in the case of purified diastase.

The destruction of the enzymic activity is not due to the formation of salts with the basic or other atomic groups of the enzyme, but the action of the acid reduces the amount of nitrogen which can be titrated in presence of formaldehyde, pointing to the formation of condensation products between the carboxyl and amino-groups.

The active component of invertase accordingly possesses a different constitution from that of diastase. E. F. A.

Action of Hydrogen Chloride on Diastase. I. THEODOR PANZER (*Zeitsch. physiol. Chem.*, 1912, 82, 276—325).—When dry hydrogen chloride is passed over purified diastase the enzyme takes up a good deal of the gas, forming with it a loose chemical compound ; the enzyme loses its specific activity. On exposure in a vacuum the hydrogen chloride is removed and the activity of the enzyme restored. It is shown that the hydrogen chloride is not fixed to the amide or secondary nitrogen atoms of the enzyme complex, and that only part is attached to the basic groups. The action of the acid does not cause any particular hydrolysis of the enzyme molecule. The specific

enzyme action of diastase is due to the atomic groups which can fix hydrogen chloride.   E. F. A.

Malt Diastase, and the Action of Potassium Phosphates on It. RUTGER C:SON HEYL (*J. pr. Chem.*, 1912, [ii], **86**, 433—457). —The author has studied the diastatic hydrolysis of starch under various conditions by determining the amount of maltose produced, according to Bertrand's method (A., 1907, ii, 136).

In the first part of its course, the diastatic actions follow the logarithmic curve, and in such a manner as if only a part of the starch were capable of hydrolysis.

The magnitude of this part depends on the concentration of the starch and of the enzyme, and also on the presence of electrolytes and proteins. In the last part of its course, the reaction proceeds with extreme slowness.

Potassium dihydrogen phosphate exercises an activating influence on the enzyme, and the same is true with respect to the action of dipotassium hydrogen phosphate on old solutions of the enzyme; in freshly prepared solutions the latter salt exerts a retarding influence.

The activating action of the phosphates is considerably influenced by the presence of proteins in the enzyme solutions.   F. B.

Reaction between Enzymes and Other Substances. SVEN G. HEDIN (*Zeitsch. physiol. Chem.*, 1912, **82**, 175—178).—Introductory to following paper.   W. D. H.

The Action of Certain Colloids on the Inhibition of Enzyme-actions. G. JAHNSON-BLOHM (*Zeitsch. physiol. Chem.*, 1912, **82**, 178—208).—Saponin completely hinders the inhibitory effect of charcoal on rennet, and partly that of normal serum. The saponin appears to liberate the enzyme which is adsorbed by the charcoal, and the reaction is a rapid one. It is accelerated by elevation of temperature, and by increase in the amount of saponin. Saponin increases the inhibitory effect of immune serum on rennet. Saponin partly activates a solution of rennet-zymogen. It acts similarly on trypsin adsorbed by charcoal, but has no effect on the antitryptic action of serum-albumin. Cholesterol acts like saponin on charcoal and rennet, but increases the inhibitory effect of normal serum. It has no influence on the antitryptic action of charcoal and serum-albumin. Egg-white if treated with hydrochloric acid and neutralised, partly inhibits the anti-rennetic power of normal serum. W. D. H.

The Coagulation of Milk by Rennet. JOHN MELLANBY (*J. Physiol.*, 1912, **45**, 345—362).—The clotting of milk by pancreatic rennet follows the same general laws as that by gastric rennet, but the two enzymes are distinct, because they differ in the effect of alkali on them; their anti-enzymes in serum are specific, and pancreatic rennet requires a greater amount of calcium than gastric rennet does. In the case of both enzymes, calcium salts may be replaced by salts of barium, strontium, or magnesium. There is no indication from electrical conductivity determinations that calcium enters into chemical com-

bination during the curdling process. The hypothesis is advanced that all proteolytic enzymes curdle milk, provided suitable conditions are provided; those, like pepsin, which act best in an acid medium requiring less calcium than those which, like trypsin, act in a alkaline medium. The coagulation of milk is due to the adsorption of the enzyme by the caseinogen, and the enzyme-caseinogen complex is precipitated by the bivalent calcium ions of the milk; the quantity of ionised calcium salt required to effect precipitation is intimately related to the quantity of enzyme adsorbed. A method based on this hypothesis is described for the detection and estimation of proteolytic enzymes. W. D. H.

The Biochemical Rôle of Peroxydases in the Transformation of Orcinol into Orcein. JULES WOLFF (*Compt. rend.*, 1912, 155, 1031—1032. Compare A., 1912, i, 928).—The action of ammonia and atmospheric oxygen on orcinol in dilute solutions is a very slow oxidation, this being the first condition for the formation of orcein. The introduction of a peroxydase influences far more the formation of the colouring matter than the amount of oxygen absorbed. W. G.

The Nomenclature of the Polyphenoloxydases. FR BATELLI and (Mlle.) LINA STERN (*Biochem. Zeitsch.*, 1912, 46, 395—396).—The authors recommend the term *polyphenoloxydase* to indicate an enzyme which accelerates the oxidation of polyphenols and the corresponding amino-derivatives. Such ferments are to be distinguished from those of the character of tyrosinase, which acts similarly on monophenols, and which are designated simply *phenoloxydases*. The expression phenolase is to be avoided in this sense, as it indicates a ferment which accelerates the hydrolysis of an aromatic ester. S. B. S.

Preparation of Organic Arsenic Compounds. HEINRICH BART (D.R.-P. 250264. Compare La Costa and Michaelis, A., 1880, 396; Schraube and Schmitt, A., 1894, i, 237).—The following organic arsenic compounds have been obtained by treating diazotised solutions of the following bases with sodium arsenite and subsequently heating in the presence of sodium hydroxide until the evolution of nitrogen ceases. p-*Bromophenylarsinic acid* (colourless needles) from p-bromoaniline; o-*benzoarsinic acid* (colourless needles) from o aminobenzoic acid; p-*acetylaminophenylarsinic acid* from monoacetyl-p-phenylenediamine; p-tolylarsinic acid (Abstr., 1880, 396) from p-toluidine: and *compounds* from potassium *iso*diazobenzene and o-nitro*iso*diazobenzene; from 4-nitro-2-aminophenol; from p-nitroaniline (which is best decomposed in tartaric or oxalic acid solutions), and from the same base decomposed in the presence of sodium p-nitrophenylarsenite; whilst p-aminophenylarsinic acid furnishes *benzene*-p-*diarsinic acid.*

The *sodium* salts of these compounds are colourless or grey needles, and the original contains numerous formulæ illustrating possible phases in their formation. F. M. G. M.

Preparation of Derivatives of 3:3'-Diamino-4:4'-dihydroxy-arsenobenzene. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 250745).—When 3:3'-diamino-4:4'-hydroxyarsenobenzene is treated with halogenated acetic acid (or its homologues) in aqueous alkaline solution it yields neutral, soluble compounds of therapeutic value.

The *compound*, $NH_2 \cdot C_6H_3(OH) \cdot As \vdots As \cdot C_6H_3(OH) \cdot NH \cdot CH_2 \cdot CO_2H$, is obtained when 3:3'-diamino-4:4'-dihydroxyarsenobenzene (100 parts), dissolved in a mixture of methyl alcohol (300 parts), and water (300 parts) containing sodium hydroxide (4 mols.), is treated with chloroacetic acid (50 parts) and potassium iodide (36 parts) and heated at 60—65° during two to three hours in an indifferent gas with exclusion of air ; the product is isolated by the limited addition of acid. The brownish-yellow *sodium* salt is precipitable with alcohol; the *potassium* and *ammonium* salts forms similar powders.

The *compound*, $NH_2 \cdot C_6H_3(OH) \cdot As \vdots As \cdot C_6H_3(OH) \cdot NH \cdot CHMe \cdot CO_2H$, a yellow powder, is prepared in a similar manner with α-bromo-propionic acid, and furnishes *alkali* salts, whilst *diaminodihydroxy-arsenobenzenediacetic acid*, $As_2[C_6H_4(OH) \cdot NH \cdot CH_2 \cdot CO_2H]_2$, is obtained with bromoacetic acid.   F. M. G. M.

Preparation of Unsymmetrical Aromatic Arseno-compounds. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 251104).—When an equimolecular mixture of two arylarsinic acids (or oxides) is reduced it yields an unsymmetrical aromatic arseno-compound.

3:4'-*Diamino-4-hydroxyarsenobenzene hydrochloride* (annexed formula), a yellow, microcrystalline powder,

HCl, NH_2 ⬡ $\cdot As \vdots As \cdot$ ⬡ NH_2, HCl / OH

is obtained as follows : *p*-Amino-phenylarsinic acid (21·7 parts) or its equivalent of *p*-aminophenyl-arsenious oxide (A., 1909, i, 347) and 23·3 parts of 3-amino-4-hydroxy-phenyl-1-arsinic acid (A., 1910, i, 803) in methyl alcohol (100 parts) and concentrated hydrochloric acid (39 parts) is slowly stirred into a mixture of stannous chloride (100 parts) dissolved in alcohol (300 parts) to which has been added 500 parts of alcohol saturated with hydrogen chloride and 17 parts of hydriodic acid (D 1·7), the temperature meanwhile being maintained at −5° to −10°, the product is slowly precipitated in crystalline form. The *sulphate* forms a flocculent, yellow insoluble precipitate.

Phenylglycylarsenious chloride, $AsCl_2 \cdot C_6H_4 \cdot NH \cdot CH_2 \cdot CO_2H, HCl$, a crystalline paste which can be washed with acetic acid and ether, is prepared by reducing a concentrated hydrochloric acid solution of phenylglycylarsinic acid (to which a trace of hydriodic acid has been added) with sulphurous acid at −10° ; it is decomposed readily by alkalis to the corresponding hydroxide.

3-*Amino-4-hydroxy-4'-glycylarsenobenzene* (annexed formula) is obtained as a viscous, yellow paste when molecular proportions of the foregoing chloride and 3-amino-4-hydroxyphenyl-

$CO_2H \cdot CH_2 \cdot NH$ ⬡ $\cdot As \vdots As \cdot$ ⬡ NH_2 / OH
arsenious oxide (A., 1911, i, 1055) in methyl-alcoholic solution are reduced with sodium hyposulphite at the ordinary temperature.

3': 5'-*Dichloro-3-amino*-4 : 4'-*dihydroxyarsenobenzene*, a yellow powder, is prepared from 3-amino-4-hydroxyarsenious oxide and 3 : 5-*dichloro-4-hydroxyphenylarsenious oxide*, $AsO \cdot C_6H_2Cl_2 \cdot OH$, which latter compound is obtained by the reduction of dichloro-*p*-hydroxyphenylarsinic acid (*loc. cit.*); 3-*amino-4-hydroxyarsenobenzene*, $C_6H_5 \cdot As_2 \cdot C_6H_3(NH_2) \cdot OH$, a fawn-yellow powder, is prepared from phenylarsenious oxide and 3-amino-4-hydroxyphenylarsenious oxide. F. M. G. M.

Preparation of Products Reduced Beyond the Arseno-stage from Substituted Aromatic Arsinic Acids. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 251571).—It is found that when powerful reducing agents (such as tin, zinc, or iron) in concentrated acid solution act on arylarsinic acids that they can be reduced beyond the arseno-condition (compare Palmer and Dehn, A., 1902, i, 86).

The following *compounds* are described :

(1) From *p*-hydroxyphenylarsinic acid as a colourless precipitate, soluble in alkalis, and isolated by means of carbon dioxide; it darkens at 75° and decomposes violently at 155°.

(2) From *p*-aminophenylarsinic acid, a colourless oil, b. p. 132°/ 10 mm., which exposed to air is rapidly converted into diaminoarsenobenzene.

(3) From phenylglycylarsinic acid, a colourless precipitate which rapidly darkens, and is isolated in the form of its *zinc* salt.

(4) From 3-nitro-4-hydroxyphenylarsinic acid (A., 1910, i, 803), isolated as its *zinc* salt; the free *arsine* is a colourless powder darkening at 100° and decomposing violently at 135°.

F. M. G. M.

Formation of Organo-metallic Compounds during Electrolytic Reductions. JULIUS TAFEL (*Ber.*, 1912, 45, 3321).—Polemical against Law (T., 1912, 101, 1016, 1544). A claim for priority. Law's statement that the formation of organo-metallic compounds at mercury cathodes has never been observed is incorrect (compare A., 1906, i, 941; 1911, i, 764). T. S. P.

Chemico-therapeutical Researches on Mercury Compounds. Mercuridi-*p*-aminophenol. ERNEST FOURNEAU and A. VILA (*J. Pharm. Chim.*, 1912, [vii], 6, 433—441).—p-*Nitrophenylmercuric acetate*, $C_8H_7O_5NHg$, obtained by the action of mercuric acetate on sodium *p*-nitrophenol dissolved in boiling water, crystallises in flattened, colourless needles, and on treatment with carbon dioxide furnishes the corresponding *oxide* (compare A., 1911, i, 1056). The latter by a complex series of reactions, which are discussed in detail in the original, gives with sodium sulphide, *sodium di-p-nitromercuridiphenol*, $C_{12}H_{10}O_6N_2HgNa_2$, crystallising in garnet-red needles, from which the corresponding *mercuridi-p-nitrophenol* is liberated by the action of acids. This on reduction in alkaline solution by sodium hyposulphite yields *di-p-aminomercuridiphenol*, $Hg[C_6H_3(OH)NH_2]_2$, crystallising in heavy needles, insoluble in water, but readily soluble in alcohol; the *hydrochloride* forms brilliant needles soluble in water. The free base oxidises rapidly in alkaline solution on exposure to air.

This substance is toxic, producing the ordinary symptoms of mercurial poisoning, due no doubt to the liberation of simple mercury derivatives by oxidation in the organism. The *acetyl* derivative crystallises in slender needles, is soluble in alkalis, forming stable solutions, and is much less toxic than the parent base.   T. A. H.

Preparation of Nuclear-substituted Mercury Derivatives of Polysubstituted Phenols. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 250746. Compare A., 1911, i, 1056; 1912, i, 754).—Organic mercury compounds have previously been prepared (compare Dimroth, A., 1902, i, 656, and *loc. cit.*), and the following more complex derivatives are now described.

The crystalline *compound*, $OH \cdot C_6H_2Me_2 \cdot Hg \cdot OAc$, is obtained when 12 parts of *p*-xylenol (A., 1878, ii, 410) dissolved in methyl alcohol are treated with mercuric acetate (30 parts) in water (100 parts) and gently warmed until the addition of an alkaline hydroxide ceases to precipitate mercuric oxide.

Similar *compounds* from creosol, pyrogallol 1 : 3-diethyl ether (A., 1878, ii, 869), and from bromo-*p*-xylenol (A., 1878, ii, 410) are described in the original.   F. M. G. M.

Preparation of Derivatives of Aminobenzoic Acid and its Salts Containing Mercury in the Ring. VEREINIGTE CHEMISCHE WERKE AKTIENGESELLSCHAFT (D.R.-P. 249725).—When the mercury salts of *o*-, *m*- or *p*-nitrobenzoic acid are heated during some hours at about 225°, the mercury becomes attached to a ring carbon atom ; these *nitro*-compounds can then be reduced to the corresponding amines.

pp-*Diamino*-oo′-*mercuridibenzoic acid* (annexed formula), a colour-less (to yellow) crystalline powder, is obtained by reducing the nitro-compound with ferrous sulphate in alkaline solution ; the crystalline *hydrochloride* can be isolated by means of alcohol. The *barium, calcium, silver*, and *lead* salts are precipitable ; the nickel salt gives a greenish-blue, and the iron salt a brown, solution ; the green solution of the copper salt becomes brown when boiled, a characteristic which distinguishes it from the solution of the copper salt of the nitro-compound, which is blue and unaffected by boiling.

The ortho- and meta-compounds have similar reactions, and are obtained by the same method ; or the mercury salt can be replaced by other salts of aminobenzoic acids, which are then heated with a salt of mercury.   F. M. G. M.

Preparation of Dinitrodiphenylmercuridicarboxylic Acids. VEREINIGTE CHEMISCHE WERKE AKTIEN GESELLSCHAFT (D.R.-P. 251332. Compare preceding abstract).—A further account of the preparation of *pp*-dinitro-*oo′*-mercuridibenzoic acid, in which a catalyst, such as stannous chloride or ferrous hydroxide, is employed to assist the condensation ; together with the preparation and properties of the *sodium, silver, barium, nickel*, and *cobalt* salts.
mm'-Dinitro-*oo'*-mercuridibenzoic acid and its *sodium, silver, barium, nickel,* and *iron* salts are also described ; the salts of these compounds are extremely poisonous, and possess a powerful therapeutic action. F. M. G. M.

Preparation of Esters of Aromatic Carboxylic Acids containing Mercury and their Products of Hydrolysis. WALTER SCHOELLER and WALTHER SCHRAUTH (D.R.-P. 248291. Compare A., 1912, i, 754).—When glycyl salicylate (182 parts) and mercuric acetate (318 parts) are boiled together during several hours in methyl-alcoholic solution, a crystalline *ester*, m. p. 165—170° and containing 45·5% Hg, is obtained, which, on hydrolysis, furnishes a compound identical with "hydrargyrum salicylicum." Methyl anthranilate (165 parts) under similar conditions furnishes a *product*, m. p. 191°, containing 47·28% Hg, and on hydrolysis an inner *anhydride* containing 57·3% mercury ; whilst *iso*butyl *p*-aminobenzoate yields a *compound*, m. p. 208° (decomp.), with mercury content 44·24%, and an *anhydride* containing 59·51% Hg.

The *phenyl glycyl* ester has m. p. 128—131°, contains 45·9% Hg, and the corresponding *anhydride* has 57·3% Hg. F. M. G. M.

Physiological Chemistry.

The Regulation of Neutrality by the Respiratory Centre, and its Stimulability in Maintaining the Carbon Dioxide Tension of the Blood. KARL A. HASSELBALCH (*Biochem. Zeitsch.*, 1912, 46, 403—439).—The conception underlying these investigations is the following : The magnitude of the lung ventilation is regulated by the magnitude of the stimulus and the stimulability of the breathing centre. The stimulus is the excess of the hydrogen-ion concentration above normal of the blood. A given magnitude of stimulus will cause a greater ventilation of the lungs the greater the stimulability of the centre, and vice versa. The C_H of the blood will alter therefore in the inverse ratio to the stimulability of the centre. This theory was tested in the following way : Considerable changes in the C_H of the urine were brought about on normal individuals by changes in the diet. The magnitude of the changes thus caused were greater than deviations from the normal found in pathological urine. The effect of such a change was to cause a change in the tension of the alveolar carbon dioxide in an opposite direction. It was experimentally shown, furthermore, that the changes in diet did not affect the stimulability of the centre. This fact was ascertained by measuring the effect on the respiration of breathing increased quantities of carbon dioxide. It was further found that the C_H of the blood (measured under a constant carbon dioxide tension) altered under varying conditions of diet, in the

same direction as the C_{H} of the urine. The alveolar carbon dioxide tension appears to alter in such a way that the actual C_{H} of arterial blood (measured under the same carbon dioxide tension as exists in the arteries) remains a constant under the varying conditions. The theory is supported by experiments in which the stimulability of the centre was artifically diminished (as, for example, by morphine) or increased.   S. B. S.

Absence of Apnœa After Forced Breathing. WALTER M. BOOTHBY (*J. Physiol.*, 1912, **45**, 328—337).—In some persons, forced breathing is not followed by apnœa; the loss of carbon dioxide consequent on forced breathing is made up within a few minutes, but not so rapidly as when apnœa occurs. This exceptional condition is probably due to a compensating diminution of the circulation through the respiratory centre, in consequence of which the gas tensions in the centre are still capable of exciting it.   W. D. H.

The Differences in Composition between Arterial and Venous Blood. HUGO WIENER (*Zeitsch. physiol. Chem.*, 1912, **82**, 243—265).—The total protein in the blood of the renal vein is less than in that of the carotid artery and femoral vein (dog). Venous blood is relatively rich in globulin, but this is not so marked in the blood of the renal vein. In nephritis, the reverse obtains.
                                                         W. D. H.

Distribution of Sodium and Potassium in the Animal Organism. P. J. GÉRARD (*Chem. Zentr.*, 1912, ii, 846—847; from *Bull. Sci. pharm.*, 1912, **19**, 265—283).—In three successive venesections. the ratio K : Na in rabbit's blood varied between 0·68 and 0·61. The sodium in contrast to the potassium remained constant, deficiences of the former being replaced by sodium withdrawn from the tissues. The ratio was also determined in various marine and land animals, and in various secretions. The author, when working with mice and frogs, was unable to confirm the antagonistic action of sodium salts on the toxic action of potassium salts, as demonstrated by Loeb in the case of *Fundulus*. The toxic action of potassium depends to a large extent on the concentration of the solution employed.   S. B. S.

The Influence of Nitrogenous Metabolism Products which Occur Naturally in Blood and Urine on the Blood Pressure. E. LOUIS BACKMAN (*Chem. Zentr.*, 1912, ii, 624; from *Zentr. Physiol.*, 1912, **26**, 166—169).—Urea in from 2—10% solutions in saline caused a rise of blood-pressure (maximum 26 mm. mercury) when injected into rabbits. Ammonium carbamate in 0·5% solution caused a lasting rise, whereas in 0·1% solution it exerted no action. Ammonium carbonate in 0·6% solution caused a lowering of blood-pressure (maximum 38 mm.), but in 0·1% solution a lasting rise. Six °₀ ammonium hippurate caused a transient rise (9 mm.), followed by a lowering. Three % solutions caused a slight rise. Creatine, hypoxanthine, and sodium urate caused lasting rises. Allantoin in

2% solution caused a lasting rise (maximum 5 mm.), and in 1% also a rise after a considerable latent period. Urea also exerts an influence on the heart beats. A mixture of 2% urea, 0·05% ammonium carbamate, 1% sodium hippurate, 1% creatine, 0 2% hypoxanthine, 0·01% xanthine, 0·03% sodium urate causes a large (maximum 46 mm.) and long lasting rise, but has small influence on the frequency of the heart beat. The investigations indicate that nitrogenous metabolism products exert an autoregulatory function in the organism, and their action explains certain pathological conditions in gout and nephritis.

S. B. S.

The Part Played by the Suprarenals in the Normal Vascular Reactions of the Body. G. von ANREP (*J. Physiol.*, 1912, 45, 307—317).—Stimulation of the splanchnic nerves causes a rise of blood-pressure, which occurs in two phases. The second phase is accompanied by constriction of peripheral blood-vessels (even after denervation) and by increased cardiac activity (also after denervation). This second rise is due to discharge of adrenaline into the circulation, and is absent after extirpation of the two suprarenal glands.

W. D. H.

Local Vascular Reactions and their Interpretation. G. von ANREP (*J. Physiol.*, 1912, 45, 318—327).—The contraction of blood-vessels, described by Bayliss as a local reaction of the vessel wall to increased internal pressure, is due to the action of adrenaline, the secretion of which is increased under the conditions of his experiments. The dilatation of blood-vessels, ascribed by Bayliss to lowering of internal pressure, is due to the direct action on the vessel walls of asphyxial products.

W. D. H.

Glycolysis. III. The Influence of Glycine and Boric Acid Anions on the Oxidative Destruction of Dextrose in the Presence of Phosphates. WALTHER LÖB and S. GUTMANN (*Biochem. Zeitsch.*, 1912, 46, 288—295. Compare A., 1911, ii, 504).—It has been already shown that phosphate mixture accelerates the destruction of dextrose by hydrogen peroxide. This is not due to the neutrality of the medium, but is specific for phosphates, as no acceleration takes place when neutral borate or other mixtures of the same hydrogen-ion concentration are employed. The authors now show that the addition of such a borate mixture to the phosphate mixture exerts no very marked action, whereas a similar glycine mixture (prepared according to Sörensen) exerts a marked inhibitory action on the glycolysis.

S. B. S.

The Significance of Proteolysis in Specific Hæmolysis. KOHSHI OHTA (*Biochem. Zeitsch.*, 1912, 46, 247—252).—An immune serum (sheep's blood into rabbit) hæmolyses the specific blood (of sheep) without any proteolysis.

S. B. S.

The Influence of the Hydrogen-ion Concentration on Specific Precipitin Reactions. LEONOR MICHAELIS and HEINRICH DAVIDSOHN (*Biochem. Zeitsch.*, 1912, 47, 59—72).—The forma-

tion of specific precipitins and agglutins is, within wide limits, independent of the hydrogen-ion concentration. This factor only comes into play, to any extent, when the reacting substances are in very dilute solutions. In this respect, the precipitin reaction differs from the non-specific precipitation of colloids, as no optimal conditions for precipitin reaction, analogous to the isoelectric point, could be discovered. These results indicate that there is some specific chemical affinity coming into play, and the electric charge of the particles plays only a subordinate part. S. B. S.

The Coagulation of Blood. ERNST FULD and ERICH SCHLESINGER (*Chem. Zentr.*, 1912, ii, 1569; from *Berlin klin. Woch.*, 1912, 49, 1323—1327).—Dialysis of the blood against an isosmotic salt solution deprives the plasma of its power of coagulating, the crystalloid which is removed being the calcium salt of fibrin. The absence of this salt also hinders the formation of another necessary element in coagulation, namely, the fibrin ferment, for the development of which, cytothrombin from the cells and plasmothrombin from the plasma are also necessary. The injection of cytothrombin into a vein at once causes coagulation, owing to the formation of this ferment, *neothrombin*. The smallest amounts of enzymes would soon set up fermentation processes, which would hinder the circulation, were there not also present substances which prevent coagulation.

Fibrin may be redissolved by fibrinolysis, which is partly due to salt action and also to an enzymatic agent, *thrombase*. J. C. W.

The Dissociation of Oxyhæmoglobin in Human Blood During Partial Carbon Monoxide Poisoning. J. B. S. HALDANE (*Proc. physiol. Soc.*, 1912, xxii–xxiv; *J. Physiol.*, 45).—The presence of carboxyhæmoglobin in the blood delays the dissociation of the oxyhæmoglobin present, so that even though the amount of oxyhæmoglobin may be half the normal (as it may also be in a man with anæmia without grave results), the combination of the remaining half of the hæmoglobin with carbon monoxide produces a serious state of affairs. W. D. H.

Blood-relationships of Animals as Displayed in the Composition of the Serum-proteins. I. A Comparison of the Serum of the Horse, Rabbit, Rat, and Ox in the Normal and Fasting Condition. T. BRAILSFORD ROBERTSON (*J. Biol. Chem.*, 1912, 13, 325—340).—The amounts of insoluble globulin, total globulin, and total albumin in serum were determined by the author's refractometric method. In the rabbit the results agree with those arrived at by others in other ways. Horse serum yields not more than 40% of the total albumin in crystalline form. In fully fed animals the three groups of proteins vary greatly; but the average values are characteristic of the species. In fasting, the total protein is also highly variable; in starvation it rises. In rabbit, ox, and horse, inanition increases the relative amount of albumin, whereas in rat and dog the reverse obtains. W. D. H.

The Diastatic Action of Human Saliva. GOICHI HIRATA (*Biochem. Zeitsch.*, 1912, 47, 167—183).—The diastatic value of saliva (as determined by Wohlgemuth's method) remains practically constant throughout the day, and is not influenced by the time of meals or the diet. The value is also independent of the amount of saliva secreted, and of the age or sex of the individual. It has the same value in certain pathological cases investigated as in normal cases, and appears to be uninfluenced by the hæmoglobin content of the blood. In the case of the Japanese, it varies between D_{50}^{35} 160 and 640 in different individuals. S. B. S.

Formation of Hydrochloric Acid in the Stomach. J. LÓPEZ-SUÁREZ (*Biochem. Zeitsch.*, 1912, 46, 490—499).—The author discusses the evidence as to the acid-secreting function of the oxyntic cells of the stomach, and considers that this has not been demonstrated. By direct chemical analysis he shows that the mucous membrane of the fundus contains more chlorine than that of the pylorus. He shows, furthermore, by Macallum's histological method that the ordinary cells contain more chlorine than the oxyntic cells. S. B. S.

The Fat-hydrolysing Ferment in Gastric Juice, and its Estimation. HEINRICH DAVIDSOHN (*Chem. Zentr.*, 1912, ii, 1378—1379; from *Berl. klin. Woch.*, 1912, 49, 1132—1134).—Rona and Michaelis's drop method for following the course of butyrin hydrolysis (A., 1911, ii, 302) has been applied to a large number of gastric juices, and a widely varying enzyme action has been observed. Directions are given whereby the method may be applied to the estimation of this hydrolytic enzyme. J. C. W.

Tryptic Digestion of Cynoscion regalis. GEORGE F. WHITE and ADRIAN THOMAS (*J. Biol. Chem.*, 1912, 13, 111—116).—The flesh of *Cynoscion regalis*, an American fish known commonly as the weakfish or squeteague, was subjected to tryptic digestion in vitro, and the amino-acids in the digest were determined by Sörensen's formaldehyde method. The results were regular and in accord with those obtained by van Slyke's nitrous acid method for estimating amino-nitrogen. The relatively low rate at which the protein becomes soluble agrees with the results of metabolism experiments. Very low cleavage products are formed as soon as the protein passes into solution, the average size of the peptides being 2·02 after half an hour's digestion; but there is a very stable nitrogen complex which is not attacked by trypsin. W. D. H.

Animal Calorimetry. V. The Influence of the Ingestion of Amino-acids on Metabolism. GRAHAM LUSK and J. A. RICHE (*J. Biol. Chem.*, 1912, 13, 155—184. Compare A., 1912, ii, 1189).—After giving meat, the metabolism of the dog during the second hour rose almost to a maximum, and the respiratory quotient was 0·9; it therefore appears that carbohydrate and not additional protein is oxidised during this period. After the ingestion of amino-acids and especially of glycine, there is a similar increase in the metabolism;

this can have nothing to do with deamidation or urea-formation, but is attributed to a direct stimulating action of the amino-acids on the cells of the body.   A mixture of five amino-acids produced a more rapid metabolism than when given singly, and more than meat containing the same amount of nitrogen.   W. D. H.

Animal Calorimetry. VI. The Influence of Mixtures of Food-stuffs on Metabolism. GRAHAM LUSK and J. A. RICHE (*J. Biol. Chem.*, 1912, 13, 185—208).—Further details are given of the effect of diet on metabolism, and the conception of the process put forward is that to a basal metabolism (at rest) there may be added metabolism due to plethora, that is, an increased supply of fats and carbohydrates, or the superadded metabolism may be due to the stimulus of amino-acids.   When these two are added to each other there is no summation of effects.   W. D. H.

Fatty Acid Metabolism in the Liver. II. The Relation of the Fatty Acids in the Food of the Plaice to those in their Livers and Myotomes. V. H. MOTTRAM (*J. Physiol.*, 1912, 45, 363—369).—The fatty acids of the mussel have a high iodine value, which falls between that of the fatty acids of the liver and those of the myotomes of the plaice.   Such fatty acids are therefore not characteristic of the vertebrates, and they occur before the appearance of a true liver.   Their formation is not exclusively a liver function.   The experiments on the feeding of plaice on mussels cannot, however, be considered a refutation of Leathes' theory of the desaturating influence of the liver in fatty acid metabolism.   W. D. H.

The Biochemical Synthesis of Fatty Acids from Carbohydrates. IDA SMEDLEY (*Proc. physiol. Soc.*, 1912, xxv—xxvii; *J. Physiol.*, 45).—Various hypotheses to explain the conversion of carbohydrate into fat are discussed.   Although pyruvic and other α-keto-acids have not yet been detected in the tissues, the theory is favoured that pyruvic acid is an intermediate product.   W. D. H.

Maintenance Experiments with Isolated Proteins. THOMAS B. OSBORNE, LAFAYETTE B. MENDEL, and EDNA L. FERRY (*J. Biol. Chem*, 1912, 13, 233—276).—Details are given and general questions discussed on the nutrition of white rats for long periods on foods containing a single purified protein.   With the precautions described this is possible, and they can be so maintained for periods equal to their adult lives.   This is true for gliadin, edestin, and casein, which are proteins of very different composition.   As glycine is absent from casein, lysine and glycine from gliadin, and phosphoproteins from gliadin and edestin, and purines throughout are practically absent, the synthetic activities of the animal body are clearly brought to mind.   The possibilities of transmutation of amino-acids must be considered, and the view that proteins as near as possible in constitution to those in an animal's body are most nutritious must be regarded with caution.   Long-continued experiments are necessary in all such work. Changes in the nitrogen balance over short periods may be entirely deceptive.   W. D. H.

The Influence of Lecithin on the Nitrogen and Phosphorus Balance. ALDO PATTA (*Chem. Zentr.*, 1912, ii, 939—940 ; from *Arch. Farm. sperim.*, 1912, 13, 515—528).—Small quantities of lecithin (0·05 to 0·10 gram) administered subcutaneously to a dog scarcely altered the nitrogen and phosphorus metabolism when there was a small deficit in these substances. Larger doses (0·5 to 0·75 gram) caused a sparing action, which was small when the nitrogen and phosphorus ingested were insufficient, but was marked when these elements were in excess of the body needs. The sparing action of the phosphorus was larger than the amount injected as lecithin, and the fact that the injection caused an increase of the nitrogen in the urine, at the expense of the fœcal nitrogen, indicates that the lecithin stimulates the degradation of the injested proteins.　　　　S. B. S.

Retention of Nitrogen after Feeding on Ammonium Salts. E. GRAFE (*Zeitsch. physiol. Chem.*, 1912, 82, 347—376).—The present experiments on pigs confirm those previously recorded on dogs (A., 1912, ii, 659). Administration of ammonium salts mixed with abundance of carbohydrate leads to nitrogenous equilibrium, or even a retention of nitrogen.　　　　W. D. H.

The Creatine Metabolism of the Growing Pig. ELMER V. MCCOLLUM and H. STEENBOCK (*J. Biol. Chem.*, 1912, 13, 209—218).— In some animals (for instance, the rabbit) fasting causes the appearance of creatine in the urine. In dogs, depletion of the liver of glycogen leads to the same result, and Mendel and Rose (A., 1911, ii, 1002, 1007) consider that there is a definite relationship between creatine and carbohydrate metabolism ; they further think that creatine is not a result of exogenous protein metabolism, but only of endogenous metabolism. The present experiments on pigs were planned to investigate this question, but it was found that in this animal fasting does not lead to the appearance of creatine in the urine ; this is explained in differences of metabolic habit. When a rabbit fasts the total nitrogen excreted rises, indicating an increase of protein katabolism. This does not happen in the dog, or only slightly, and not at all in the pig. The pig is an efficient fat-storer, so he might be expected to use it readily for energy production. On an uniform diet considerable irregularities in the excretion of creatine occur, and the idea that creatine is destroyed by enzymes is supported. Data are also given which leave but little doubt that creatine may arise from exogenous as well as from endogenous protein metabolism, and that its source, or one of its sources, is arginine, is regarded as probable.　　　　W. D. H.

The Behaviour of Some Hydantoin Derivatives in Metabolism. I. Hydantoin and Ethyl Hydantoate. HOWARD B. LEWIS (*J. Biol. Chem.*, 1912, 13, 347—356).—After hydantoin is given, an insoluble benzylidenehydantoin can be recovered from the urine, which accounts for only part of the hydantoin administered. No toxic effects follow, which is against Lusini's theory of the toxicity of $\begin{smallmatrix} -HN \\ -HN \end{smallmatrix}{>}C{:}O$ groups.

Hydantoic acid, of which hydantoin is the cyclic anhydride, is not destroyed in metabolism when given as the ethyl ester. The hydantoin nucleus is not destroyed in the body of cat, rabbit or dog.

W. D. H.

Purine Metabolism. X. The Property of the Organism to Destroy, or Form by Oxidative Processes, Uric Acid in Animals Capable of Producing this Acid Synthetically. VITTORIO SCAFFIDI (*Biochem. Zeitsch.*, 1912, **47**, 215—225).—In experiments carried out with ducks, it was found that animals which normally synthesise uric acid can also destroy this acid after ingestion when added to a normal diet, to the extent of 33—59% of the total. They can also degrade guanine to xanthine, and into still simpler complexes which no longer contain a purine group. From the xanthine thus formed, a certain amount of uric acid can be formed by an oxidative process. Ingestion of nucleic acid also causes a slight increase in the amount of purine bases excreted and a considerable increase in the uric acid, the origin of which is ascribed to the protein groups.

S. B. S.

The Metabolism of Endogenous and Exogenous Purines in the Monkey. ANDREW HUNTER and MAURICE H. GIVENS (*J. Biol. Chem.*, 1912, **13**, 371—388).—In the urine of the guenon monkey (*Cercopithecus*), allantoin accounts for 75% of the nitrogen arising from the katabolism of endogenous purines. The rest appears principally as purine bases, uric acid being practically absent on a purine-free diet. Allantoin is a true end-product. When purines are given, allantoin is increased, and uric acid appears as an intermediate product. Only 12—54% of total purine intake is accounted for. The deficit is probably due to decomposition prior to absorption. There is no approach in this monkey to the human type of nuclein metabolism.

W. D. H.

Absorption from the Stomach. OTTO FOLIN and HARRY LYMAN (*J. Biol. Chem.*, 1912, **13**, 389—391).—A reply to London's recent criticisms (A., 1912, ii, 1189).

W. D. H.

Behaviour of Intestinal Wall After a Prolonged Period of Functional Inactivity. PAOLO MARICONDA (*Zeitsch. physiol. Chem.*, 1912, **82**, 406—412).—After making a Vella fistula, a dog was kept for several months so that no local stimulus had reached the intestine. The amount of fluid secreted by the intestinal wall was now very small, and the amount of the various enzymes was also reduced, although not to the same extent. The results are opposed to the theory that the secretory function of the intestine is due to chemical stimuli carried to it by the blood. Sucrose introduced into the fistula passes the wall without being changed; the selective absorptive power of the intestinal wall has been destroyed.

E. F. A.

Absorption of Cholic Acid in the Dog's Intestine. BAREND C. P. JANSEN (*Zeitsch. physiol. Chem.*, 1912, **82**, 342—345).—Experiments with intestinal loops showed that in all probability cholic acid is absorbed unchanged by the intestinal wall.

W. D. H.

The Fate of Deeply-degraded Proteins in the Intestine. PETER RONA (*Biochem. Zeitsch.*, 1912, 46, 307—316).—Experiments were carried out with the object of ascertaining whether any protein synthesis takes place in the small intestine. Pieces of surviving intestine were placed in Tyrode's solution and various digestion products or mixtures of amino-acids were placed either in the solution in which the intestine was kept or introduced directly into the lumen. The experiments were carried out at 38°, and during this time the intestine maintained its peristaltic movements. The amino-nitrogen was estimated both before and after the experiment. There was generally an increase in this nitrogen at the end, due probably to amino-substances given up by the intestine itself. The amount of increase was of the same order as that in which the experiments were carried out in Tyrode's solution without any addition. No evidence was obtained therefore of any synthetical process affecting amino-derivatives in the intestine.   S. B. S.

The Investigation of the Permeability and Antagonistic Action of Electrolytes by means of a New Method. JACQUES LOEB (*Biochem. Zeitsch.*, 1912, 47, 127—166).—It has been already repeatedly shown by the author, in experiments on *Fundulus* eggs, that treatment with a solution of one salt alone (for example, sodium chloride) alters the permeability of the membrane, and that this alteration can be inhibited by the addition of certain quantities of another salt (calcium chloride). Salt solutions, of such composition that the antagonistic action of the salts is at its maximum, are designated equilibrated solutions. If fertilised eggs of *Fundulus* be brought into a solution of 50 c.c. $3M$-sodium chloride + 2 c.c. $10/8M$-calcium chloride, they will remain on the surface for three days, after which the membrane will be rendered permeable by the hypertonic solution; the eggs will then begin to shrink, and owing to the passage outwards of water, the specific gravity will increase and they will then sink in the solution. If brought into a solution of $3M$-sodium chloride alone, without presence of calcium chloride, they will sink within three to four hours, and the membrane rapidly becomes permeable. Similar phenomena are observed when the eggs are brought into other corresponding solutions containing only salts. By the method of experiment the various earlier investigations of the author have been confirmed. The changes in the permeability appear to be due chiefly to the proteins, and there is an antagonism between the action of acids and the corresponding salts, which is characteristic of proteins, as Pauli and his pupils have shown. Furthermore, the antagonism in the system H_2SO_4–Na_2SO_4 is more complete than in the system HCl–NaCl. The antagonistic action of these acids and salts on the *Fundulus* egg, as studied by the method described above, confirms the theory as to the alterations of the proteins by salts. The quantitative study of the action of alcohols, however, indicates that these alter the permeability by the action on the fatty constituents of the membrane. Provided that the action has not gone too far, the change of permeability produced by salts is a reversible one, and eggs, which have been a short time in a toxic

solution, will recover their normal properties when brought into an equilibrated solution. Eggs will also remain alive in distilled water, and fish will develop, but they will not recover their impermeability. If such eggs are brought into a solution of 50 c.c. $3M$-calcium chloride + 2 c.c. $10/8M$-calcium chloride, they sink in a few hours.

S. B. S.

The Influence of Neutral Salts on Ferment Action. II. EMIL STARKENSTEIN (*Biochem. Zeitsch.*, 1912, 47, 300—319. Compare A., 1910, i, 449).—The number of salt molecules necessary to activate to the maximum extent an inactive diastase preparation is proportional to the amount of ferment. This fact suggests a process for the determination of the quantity of ferment in a given organ. For this purpose the organ is dried, a 5% suspension of the dried powder is made up, and dialysed. The amount of salt which produces the maximum diastatic effect with this fluid can then be ascertained. By this means the diastase content in various animal organs was investigated. Organs of warm-blooded animals contain more ferment than those of the cold-blooded. The ferments obtained from both kinds of animals work more rapidly at higher temperatures.

S. B. S.

Lipoids. XVI. The Cholesterol Content of Different Parts of the Brain. SIEGMUND FRÄNKEL, P. KIRSCHBAUM, and KURT LINNERT (*Biochem. Zeitsch.*, 1912, 46, 253—256).—The cholesterol was estimated as its digitonin derivative. In a human brain 4·03% was found in the pons and medulla oblongata, 2·47% in the white matter of the cerebrum, and 1·31% in the cerebellum.

S. B. S.

The Colloidal Structure of Nerve Cells and the Changes which they Undergo. G. MARINESCO (*Zeitsch. Chem. Ind. Kolloïde,* 1912, 11, 209—225).—The ultra-microscopic structure of nerve cells is described and interpreted on the assumption that the cell constituents are of colloidal character. The structural changes which are observed, when the nerve cells are subjected to the action of acids, alkali, salts, and various other substances, such as ethyl alcohol, carbamide, glycerol, sucrose, chloral hydrate, and antipyrine, are also described in detail.

The results of these ultra-microscopic observations seem to show that the particular structures' which are presented by the nerve cells after treatment by the usual fixing and colouring methods are essentially determined by the nature of the histological processes employed. The fixing reagents have, in general, a coagulating effect on the colloidal cell constituents, and the observed facts agree with the view that the protoplasm is a negative colloid.   H. M. D.

Chemical and Biochemical Investigations on the Nervous System under Normal and Pathological Conditions IV. The Chemical Composition of the Brain in Progressive Paralysis. DOMENICO CARBONE and GIACOMO PIGHINI (*Biochem. Zeitsch.*, 1912, 46, 450—469).—The analyses of brains taken from

individuals who have suffered from progressive paralysis and Dementia præcox paraxoica were compared with those obtained from mentally normal individuals. Whereas normal brains contain about 23% of dry substance, those from mentally afflicted (five cases) varied between 17 and 21%. Against a normal value of 20%, the acetone extracts of the abnormal brains varied between 22·87% and 31·32%. The light petroleum extracts varied between 11·23% and 23·14%, as compared with the amount from normal brains of 27·84%. The cholesterol varied between 13·9 and 24·2%, and the other extractives between 4·5 and 11·84% as compared with the normal values of 10·96 and 9·64%. Full details as to analytical methods are described by the authors.   S. B. S.

Broncho-dilator Nerves. WALTER E. DIXON and FRED RANSOM (*J. Physiol.*, 1912, 45, 413—428).—The broncho-dilator nerves are of sympathetic origin. Adrenaline given to an animal showing bronchial tonus causes active temporary dilatation; atropine causes passive permanent dilatation.   W. D. H.

The Influence of Inorganic Salts on the Perfused Heart. W. BURRIDGE (*Quart. J. expt. Physiol.*, 1912, 5, 347—372).—Potassium salts give rise to two types of contraction in cardiac muscle (frog), which are termed "tonic contraction" and "contraction effect." Some salts produce one, others the other effect, but all temporarily abolish rhythmical activity, and may produce "heart block" if perfused at high pressure. The effects are mainly explained by considering that these salts displace calcium salts, and the various calcium salts are displaced at varying rates. Seasonal variations noted are explained as due to changes in the balance between calcium and potassium salts in the heart muscle; temperature may also be a factor.   W. D. H.

Physiology and Pharmacology of the Cardiac Vagus. I. The Influence of Chloral Hydrate on the Result of Vagus Stimulation. OTTO LOEWI (*Arch. expt. Path. Pharm.*, 1912, 70, 323—342).—Intravenous injection of chloral hydrate in small doses has no effect on blood pressure and heart rate, but almost completely annuls the return of the heart-beat during vagus stimulation. Large doses abolish vagus excitability. Camphor has also no effect on blood-pressure or pulse rate, but influences vagus stimulation in a similar way. The action of pilocarpine and muscarine is similarly weakened.   W. D. H.

Physiology and Pathology of the Cardiac Vagus. II. The Importance of Calcium for Vagus Action. OTTO LOEWI (*Arch. expt. Path. Pharm.*, 1912, 70, 343—350).—Partial removal of calcium by small amounts of oxalate increases the excitability towards electrical stimuli of various nerves; the least affected is the pelvic nerve, but the chorda tympani and especially the vagus are profoundly affected. This is not inhibited by calcium. The action of muscarine on the frog's heart occurs after it is rendered poor in calcium,

or free from calcium. The paralysis of the vagus by pilocarpine or muscarine in mammals and frogs is not influenced by calcium.

W. D. H.

Physiology and Pharmacology of the Cardiac Vagus. III. Vagus Excitability and Vagus Poisons. OTTO LOEWI (*Arch. expt. Path. Pharm.*, 1912, **70**, 351—368).—In very small doses muscarine (and pilocarpine) increases vagus excitability in the frog. In vagus paralysis produced by these drugs there exists neither in frog nor rabbit any automatic ventricular action. The effect of prolonged electrical stimulation of the nerve is either increased by muscarine or unaffected by it, according to the duration of the stimulation or the dose of the poison. Similarly, the pilocarpine effect can be superposed on the muscarine effect, or vice versa. Physostigmine does not sensibilise the muscarine or pilocarpine action. The action of pilocarpine and muscarine is considered to be on the myoneural junction.

W. D. H.

The Behaviour of Acetic Acid in the Artificial Perfusion of the Liver. ADAM LOEB (*Biochem. Zeitsch.*, 1912, **47**, 118—126). —Various results obtained by Embden and his school are recapitulated, and reasons are given as to why acetic acid might be expected as a normal degradation product of fats, carbohydrates, and proteins, especially through the intermediation of pyruvic acid. As no evidence could be obtained of the formation of acetic acid when pyruvic acid was added to blood in a perfusion experiment, the effect of adding the former acid itself to the blood was investigated. It was found that, during perfusion, a very marked disappearance of this acid took place. It was also found, without exception in ten experiments, that the addition of acetic acid to the perfusion of blood caused a marked increase in the formation of acetoacetic acid. The mechanism of this reaction is discussed, and it is provisionally suggested that the degradation of acetoacetic into acetic acid is a reversible process :

$$CH_3 \cdot CO \cdot CH_2 \cdot CO_2H \rightleftharpoons 2CH_3 \cdot CO_2H,$$
and for this reason the acetic acid may inhibit the degradation of the acetoacetic acid normally formed to simpler products.

S. B. S.

The Fate of Glyoxylic Acid in the Animal Body. GEORG HAAS (*Biochem. Zeitsch.*, 1912, **46**, 296—306).—On incubation of minced liver of various animals with glyoxylic acid, this substance partly disappeared, but no definite degradation products were isolated. Its perfusion through rabbit's liver gave rise to formic acid, and this acid could also be isolated in the urine of a dog which had received glyoxylic acid *per os*.

S. B. S.

The Destruction of Alkaloids by the Body Tissues. A. J. CLARK (*Quart. J. expt. Physiol.*, 1912, **5**, 385—398).—The liver of frog and rabbit possesses the power of destroying atropine ; this persists after the cells are destroyed, and is due to a soluble substance resembling an enzyme in its action. The heart and kidneys of the frog and the

blood of the rabbit have the same power in a less degree, but all the other tissues are destitute of the power. None of the tissues in cat, rat, and dog has the power, and the minimal lethal dose of atropine is highest in those animals the livers of which can destroy it.

W. D. H.

The Distribution of Nitrogen in Autolysis, with Special Reference to Deaminisations. GERTRUDE D. BOSTOCK (*Bio-Chem. J.*, 1912, 6, 388—415).—The following nitrogen fractions in the autolysis products of liver were determined: ammonia, amide nitrogen, and amino-acid nitrogen. It was necessary to ascertain these factors in order to determine the fate of ammonium salts and amino-acids when digested with liver tissue. In fresh liver the soluble nitrogen fraction is characterised by its low ammonia and amino-nitrogen content. The latter, however, increases after forty-eight hours' incubation at the expense of the undetermined nitrogen fraction. The rate of autolysis reaches its maximum within this period. Acids stimulate and alkalis depress the autolysis rate, and the distribution of nitrogen differs under these two conditions. Acids cause a lower and alkalis a higher percentage of ammonia and undetermined nitrogen fractions than in the control autolyses without addition of either acid or alkali. The reverse is the case with regard to the amide or amino-acid nitrogen. Putrefactive organisms cause a higher percentage of ammonia and undetermined nitrogen. No evidence could be obtained of the formation of amide nitrogen from ammonium sulphate or lactate when digested with liver pulp. There is also no evidence of liberation of ammonia from glycine. In view of the formation of ammonia by putrefactive organisms, any statements as to the liberation of this substance from amino-acids when digested with tissues must be received with caution.

S. B. S.

The Permeability of the Kidneys to Sugar after Repeated Injections of Adrenaline. ARTUR VON KONSCHEGG (*Arch. expt. Path. Pharm.*, 1912, 70, 311—322).—Diuresis which follows the injection of adrenaline is independent of glycosuria. After salt diuresis is produced, it is not possible to produce glycosuria by such injections; the blood contains no excess of sugar, but the kidneys themselves contain more than normal. Inhibition of glycosuria is not brought about by the kidneys being unable to take up sugar from the blood.

W. D. H.

The Amount of Silicic Acid in Human Thyroid Glands. HUGO SCHULZ (*Biochem. Zeitsch.*, 1912, 46, 376—392).—The mean content of the normal glands from the neighbourhood of Greifswald was 0·0084%, and that of pathological glands from the same district, 0·0175%. The pathological glands from Zurich, on the other hand, contained as much as 0·0434%. The author, nevertheless, gives reasons for not believing that goitre is due to water containing silicic acid, and he failed to produce the disease experimentally in animals which had received over long periods water containing relatively large quantities of the acid.

S. B. S.

The Creatine-splitting Enzyme of the Parathyroids and the Suprarenals. ALBERT HOLMES ROWE (*Amer. J. Physiol.*, 1912, 31, 169).—A creatine-splitting enzyme is present in the thyro-parathyroid tissue ; this confirms the results of Gottlieb and Stau-gassinger. A similar enzyme is found in suprarenal extract. There is no evidence that either the parathyroids or the suprarenals contain a creatine-splitting enzyme which can be activated by the other.

W. D. H.

The Chemistry of Normal and Eclamptic Placenta. L. MOHR and W. HEIMANN (*Biochem. Zeitsch.*, 1912, 46, 367—373).—Estima-tions were made of the water content, total phosphoric acid and nitrogen, ether soluble substances, cholesterol, neutral fat, and diastearyllecithin. The last-named was appreciably larger in normal placenta than in cases of eclampsia. There was no marked difference in the other factors.

S. B. S.

The Physico-chemical Basis of a Theory of Muscular Contraction (Zuntz's Theory). WILLIAM N. BERG (*Pflüger's Archiv.* 1912, 149, 195—220. Compare A., 1912, ii, 1077).—A critical and antagonistic discussion of Zuntz's theory ; the main point is that lymph contains practically no carbon dioxide in the simple gaseous condition, and that when gases are dissolved in water they behave differently from substances in true solution, and, with the exception of hydrogen chloride and ammonia, exert no osmotic pressure. The carbon dioxide which is formed by muscular activity has therefore no osmotic pressure.

W. D. H.

The Anaphylactic Reaction of Plain Muscle in the Guinea Pig. HENRY H. DALE (*Proc. physiol. Soc.*, 1912, xxvii—xxix ; *J. Physiol.*, 45).—Experiments on the plain muscle (uterus) of the guinea pig sensitised to horse-serum and other proteins ; it reacts in response to minute doses (one in a million) of the specific antigen ; after response it is completely desensitised ; it can be re-sensitised by soaking in the serum of sensitised guinea pigs. The time relations of the reaction exclude the production of a poison by parenteral digestion. The antigen acts on the sensitised muscle like a stimulant drug, the peculiar feature being that the "receptive or anti-substance" is de-tachable. There is much evidence in favour of the view that the anaphylactic anti-substance is identical with precipitin.   W. D. H.

Synthesis of Lecithin in the Hen and the Character of the Lecithins Produced. ELMER V. McCOLLUM, J. G. HALPIN, and A. H. DRESCHER (*J. Biol. Chem.*, 1912, 13, 219—224. Compare A., 1912, ii, 368).—Further experiments are given to show that hens fed on a diet free from lipoids produce eggs which contain lecithin or lecithins. These differ in the nature of their fatty acid radicles, and variation may be produced by the nature of the lipoids of the diet.

W. D. H.

Red Colouring Matter of Boiled Crabs. EUGÈNE GRANDMOUGIN (*Chem. Zeit.*, 1912, 36, 1377—1378).—The change of colour observed

when crab-shells are boiled has been attributed by Kornfeld to the formation of alizarin-red, which depends on the presence of alizarin and aluminium oxide in the unboiled shell.

The author points out that the presence of anthraquinone in the normal organism has not previously been observed. He also finds that the colouring-matter of crab- and lobster-shell, unlike alizarin-red, is soluble in alcohol or ether, and is very sensitive to light. When dissolved in alcohol, it shows characteristic absorption bands in the green portion of the spectrum which differ completely from the bands given by alizarin. It possesses no dyeing power. Finally, the presence of compounds of aluminium in the shell could not be detected with certainty.

The exact nature of the colouring matter has not been determined, but the presence of anthraquinone derivatives is extremely improbable.
                                                                    H. W.

The Bio chemistry of Termites. The Chemical Composition of the Fæcal Stalactites of Entermes monoceros. KONRAD SCHUBEL (*Arch. expt. Path. Pharm.*, 1912, 70, 303—310).—The tree ant of Ceylon protects its nest by so-called stalactites, and it has been surmised that these contain cantharidin or some similar poison. The present work shows that the material consists of an organic non-toxic substance with a small amount of inorganic salts. The ash has the following percentage composition: SiO_2, $45\cdot2$; P_2O_5, $1\cdot09$; $Fe_2O_3 + Al_2O_3$, $23\cdot5$; Mn_3O_4, $1\cdot05$; CaO, $14\cdot25$; MgO, $1\cdot5$, and $K_2O + Na_2O$, $13\cdot3$. By distillation in a vacuum it was proved that the fæcal matter contains preformed an olefine, probably $C_{35}H_{70}$, m. p. $75°$. These animals live almost exclusively on flies and algæ.   W. D. H.

Metabolism Studies on the Cold-blooded Animals. I. The Urine of the Fish. W. DENIS (*J. Biol. Chem.*, 1912, 13, 225—232). —The urine of the dog-fish is clear, odourless, and almost colourless; it is acid to litmus. It darkens and becomes cloudy when kept. It gives the murexide reaction, and contains creatinine, but not creatine. The following is the average composition, expressed in grams per litre: total nitrogen, $4\cdot2$; urea nitrogen, $3\cdot4$; ammonia nitrogen, $0\cdot3$; chlorides (as $NaCl$), $12\cdot8$; phosphates (as P_2O_5), $4\cdot5$; total sulphur (as SO_3), $7\cdot1$, and total sulphates (as SO_3), $3\cdot4$. The goose fish (*Lophius piscatorius*) is the only teleost so far investigated; in general appearance and reaction, the urine resembles that of the dog-fish; uric acid, creatine, and creatinine were absent. The one specimen examined contained, in milligrams per litre, total nitrogen, 400; urea nitrogen, 248, and ammonia nitrogen, 2.   W. D. H.

Behaviour of Alicyclic Compounds in Coupling with Glycuronic Acid in the Organism. JUHO HAMÄLÄINEN (*Chem. Zentr.*, 1912, ii, 854—856; from *Skand. Arch. Physiol.*, 1912, 27, 141—226). —A number of terpenes and allied compounds dissolved in olive oil were fed to rabbits. The urine produced was collected, and the coupled glycuronic acids formed were either isolated or the products of their hydrolysis by acids were examined.

Menthene in this way gave rise to a product which on hydrolysis yielded a *hydrocarbon*, $C_{10}H_{16}$, b. p. 178—180°, that on hydration gave a dihydric *alcohol*, $C_{10}H_{20}O_2$, m. p. 55—59°, which may be *p*-menthan-2 : 4-diol. Dihydrocarveol in the same way yielded a menthadiene, $C_{10}H_{16}$, b. p. 179—181°, which on oxidation gave dihydrocarvone, and on hydration furnished *p*-menthan-2 : 8-diol. Terpin yielded a menthadiene, b. p. 178—181°, which gave terpin hydrate and terpineol on hydration, and terpenylic acid on oxidation with chromic acid. Menthone, before coupling with glycuronic acid, appears to be oxidised to Δ^4-menthen-3-one, since the latter is produced on hydrolysis of the coupled product.

Thujone is apparently first converted in the organism into *p*-menthan-2-one-4-ol by addition of 1 mol. of water. On hydrolysis the coupled product yields carvenone, whilst oxidation with sodium hypobromite gives ω-dimethyllævulic acid. Thujyl alcohol, under like conditions, seems to be converted into *p*-menthan-2 : 4-diol, since the latter is formed on hydrolysis of the coupled glycuronic acid produced in the organism.

Sabinol yields *sabinolglycuronic acid*, $C_{16}H_{24}O_7$, m. p. 82—83°, as a colourless, glassy mass, giving crystalline *sodium* and *strychnine* salts. The latter has m. p. 196—197°, $[\alpha]_D^{20}$ – 39·66° in alcohol, and crystallises with $2H_2O$ in needles from hot water. Sabinene yields a coupled product, which on hydrolysis with 5% sulphuric acid gives a gelatinous substance that on hydrolysis with stronger acid yields Δ^1-menthenone (?).

Pinene and nopinene appear to undergo oxidation before coupling, since the coupled product yields *p* cymene on hydrolysis. Camphane is also oxidised in the organism, and yields a mixture of d- and l-*bornolglycuronic acids*, $C_{16}H_{26}O_7$, m. p. 163—165°, $[\alpha]_D^{20}$ – 56·91°, as a colourless, crystalline mass.

l-Fenchyl alcohol furnishes *fenchylglycuronic acid*, $C_{16}H_{26}O_7,H_2O$, m. p. 124—126°, $[\alpha]_D^{21}$ – 63·07°, crystallising from acetone and yielding well crystallised salts. 1-iso-*Fenchylglycuronic acid*, m. p. 140—150°, $[\alpha]_D^{20}$ – 81·02°, is amorphous.

Camphenilolglycuronic acid, $C_{15}H_{24}O_7$, m. p. 150—153°, is a colourless mass, obtained by the use of either camphenilol or camphenilone, the latter apparently undergoing initial reduction in the organism.

α-Santenol gives rise to *α-santenolglycuronic acid*, $C_{15}H_{24}O_7,H_2O$, m. p. 160—161°, $[\alpha]_D^{11}$ – 56·6°, a colourless mass, which yields crystalline salts. *β-Santenol* also couples unchanged, furnishing β-santenolglycuronic acid, which was not isolated, but was found to yield santene on acid hydrolysis. Santenone is first oxidised to *santenonol*, $C_9H_{14}O_2$, m. p. 92—93°, crystallising in colourless leaflets, giving a crystalline *semicarbazone*, m. p. 222—223°, and yielding santenic acid on oxidation. *Santenonolglycuronic acid*, $C_{15}H_{22}O_8$, yields a crystalline *strychnine* salt, $C_{36}H_{44}O_{10}N_2,2H_2O$, m. p. 171—172°, and gives santenonol on hydrolysis.

Camphene hydrate couples unchanged with glycuronic acid in the organism, and the product on hydrolysis gives camphene, by loss of water from the regenerated camphene hydrate. T. A. H.

The Relationships between Tumour Cells and Blood-serum. ERNST FREUND and GISA KAMINER (*Biochem Zeitsch.*, 1912, 46, 470—482).—The property possessed by normal sera of destroying carcinoma cells is due to an ether-soluble, nitrogen-free fatty acid. The property of carcinomatous serum of protecting carcinomatous cells from destruction, and of giving specific turbidity with saline extracts of carcinomas, is due to the euglobulin (nucleoglobulin) fraction of the serum which is soluble in sodium carbonate, and is distinguished from normal nucleoglobulin by its high content of carbohydrate group. The property of carcinoma extracts of giving turbidities with carcinomatous sera is due to a nitrogen-free carbohydrate compound. The specific precipitates of carcinomatous and sarcomatous extracts with their respective sera are characterised in the former case by carbohydrate-rich substances, and in the latter case by groups yielding the biuret reaction. The carcinomatous precipitates carry down from solution added carbohydrates, whereas the sarcomatous precipitates carry down added peptone. The tumour cells themselves show a similar adsorptive capacity, the carcinomatous cells binding sugar, lecithin or nuclein, whereas the sarcomatous cells bind peptones and nuclein. S. B. S.

The Interstitial Granules (Liposomes) in Fatty Metamorphosis of Striated Muscle. E. T. BELL (*J. Path. Bact.*, 1912, 17, 147—159).—Fatty metamorphosis may be produced in the leg muscles of a rat by applying a ligature round the thigh ; in the fibres of these muscles the liposomes stain with greater intensity, and are much larger than normal ; this is especially the case in well nourished animals, or if the rat is fed on fat. Pathological fatty metamorphosis is an exaggeration of a normal process, and consists in an increase in the size, staining capacity, and often the number of liposomes. Part of the fat is already present when the process begins. The increase of size is probably due to the accumulation of triolein. W. D. H.

Nature of the So-called Klausner Serum Reaction. G. KLAUSNER (*Biochem. Zeitsch.*, 1912, 47, 36—58).—The author has already shown that sera from certain cases of syphilis yield a precipitate when diluted with three times the volume of water. This property is lost if the serum is previously extracted with ether, and is restored by the addition to the serum of the lecithin–cuorin–cephalin fraction of brain lipoids. A serum can also be rendered non-precipitable by water if heated, but in this case the precipitability (activation) is not restored by lipoids. A serum activated by brain lipoids can also be inactivated by heating. The property of restoring activity by lipoids is not destroyed by heating. An artificially activated serum (by lipoids) if inactivated by heat is not rendered active again by the addition of fresh serum ; hence, the activating property of lipoids is best if they are heated in the presence of serum. In all cases both of artificial and natural precipitin reactions, the optimal condition for precipitation is dilution with three times the volume of water. The natural precipitin reaction, when destroyed by heat, is not restored on the addition of fresh serum. A positive serum, inactivated by extraction with ether, can be reactivated

by the addition of the ethereal extract, which can also activate a normal inactive serum. Strong concentrations of the ethereal extracts of normal serum, dissolved in water, can also activate a normal serum. These results indicate that the precipitation is not due to globulins, and that in syphilitic sera the abnormalities are due to excess of lipoids.   S. B. S.

Bence-Jones Proteinuria. E. PROVAN CATHCART and J. HENDERSON (*J. Path. Bact.*, 1912, **17**, 238—248).—A detailed account of the examination of the urine in a case of this disease. The general result of an examination of the protein present is that the findings of Hopkins and Savory (A., 1911, ii, 417) are confirmed.   W. D. H.

The Action of Carbon Dioxide on the Vascular System. S. ITAMI (*J. Physiol.*, 1912, **45**, 338—344).—Small percentages of carbon dioxide produce a rise of arterial pressure mainly by increasing the force of the heart. Higher percentages (over 8%) produce increased constriction of the arterioles by stimulating the vaso-motor centre, and probably from an increased activity of the suprarenal glands.   W. D. H.

Diuretic Action of Mercury Preparations. D. FERRON (*Chem. Zentr.*, 1912, ii, 370; from *Arch. Farm. sperim.*, 1912, **13**, 283—288). —Intravenous injection of doses of 0·000010 to 0·000025 gram-equivalents of mercuric chloride per kilo. of body-weight causes in rabbits an appreciable diuresis, but in larger doses the effect is less than that of the saline injection alone, owing to the toxic properties. A simultaneous injection of sodium chloride decreases the toxic effects, and, vice versa, mercuric chloride diminishes the toxic effects of hypertonic sodium chloride solution.   S. B. S.

Action of Mercury Preparations on Spirochaete Diseases. I. Chemical-therapeutic Action of Mercury Compounds, Especially of a New Mercury Preparation which Strongly Attacks Spirochaete, but is only very Slightly Poisonous WILHELM KOLLE, M. ROTHERMUND, and S. PESCHIÉ (*Chem. Zentr.*, 1912, ii, 1574—1575; from *Deut. med. Woch.*, 1912, **38**, 1582—1585).—The therapeutic action of many mercury preparations, such as colloidal mercury, mercury peptonate, dinitromercuridibenzoic acid, sulphaminophenyldimethylpyrazolonemercury, etc., has been examined. The aliphatic compounds do not differ very much in their action, but the benzene and pyrazolone compounds show many differences in toxicity and in the relation of the curative to the toxic dose. Sulphamino-compounds show a great lowering of the poisonous nature of mercury preparations without a diminution in their spirillocidal properties, and sulphaminophenyldimethylpyrazolonemercury is especially to be recommended.   J. C. W.

Action of Mercury Preparations on Spirochaete Diseases. II. The Toxicology and Pharmacology of Some Mercury Compounds. J. ABELIN (*Chem. Zentr.*, 1912, ii, 1575; from *Deut. med. Woch.*, 1912, **38**, 1822—1825. Compare preceding abstract).—The poisonous nature of mercury compounds is influenced by their

chemical constitution ; the introduction of sulpho- or amino-groups or of doubly-linked carbon atoms diminishes their toxicity. The most poisonous compounds are those in which the mercury is easily ionised, such as mercuric chloride. After injection of mercury preparations, the metal is always found in the liver.   J. C. W.

The Sugar of the Blood and Urine under the Influence of Continuous Adrenaline Infusion. M. J. GRAMENITZKI (*Biochem. Zeitsch.*, 1912, 46, 186—209).—Adrenaline was continuously administered to rabbits by Straub's infusion apparatus, and the effect on the sugar content in the blood and urine with varying dilutions of the drug was ascertained. It was found that there is in general a proportionality between the strength of the adrenaline stimulus, and both the resulting hyperglycæmia and glycosuria. Under urethane narcosis, the amount of adrenaline necessary to produce glycosuria is below the normal. Under these conditions, the strength of the adrenaline stimulus necessary to produce glycosuria is less than that required to raise the blood-pressure. The adrenaline administration increases the diuresis within a few minutes, and this effect is often, but not always, accompanied by glycosuria. The diuretic effect of urethane is to be ascribed to its urea components, whereas its glycosuric effects can only be partly ascribed to these.

Under urethane narcosis, artificially introduced sugar disappears more slowly than in normal animals ; it also disappears more slowly from bound animals than from animals which are free. Venesection causes a distinct but slight hyperglycæmia, which is sometimes accompanied by glycosuria. The effects of the narcotic, etc., were investigated in some detail in view of criticisms on Ritzmann's work, which was also carried out in Straub's laboratory. In experiments on non-narcotised animals, it was found that the proportionality between the adrenaline stimulus and the effects was more marked than in the narcotised animals. The primary effect is hyperglycæmia, which can be quite marked (up to 0·2%) even when there is no glycosuria. The smallest stimulus necessary to produce glycosuria is higher in non-narcotised than in narcotised animals. The diuretic action of adrenaline follows definite laws, and is independent of the glycosuric effect. The general theory of the drug action is discussed.   S. B. S.

Effect of Adrenaline on the Pulmonary Circulation. E. M. TRIBE (*Proc. physiol. Soc.*, 1912, xx—xxii ; *J. Physiol.*, 45).—The conflicting results of previous workers on this question are probably due to the use of different preparations. Adrenaline preparations free from preservative cause constrictions at body temperatures. Preparations of adrenaline chloride preserved with 0·5% chloretone cause distinct dilatation of the pulmonary vessels. The constriction obtained with pure adrenaline is, however, hardly comparable with that seen in organs supplied by vaso-motor nerves, and the question of the existence of such nerves in the lung-vessels is left undecided.

                                                         W. D. H.

The Vascularity of the Liver. VIII. The Influence of Adrenaline on the Arterial Inflow. RUSSELL BURTON-OPITZ (*Quart. J. expt. Physiol.*, 1912, 5, 309—324).—The complex nature of the blood supply of the liver renders the interpretation of records a matter of difficulty, and much of this and the following papers is devoted to a discussion of this question. There appears, however, no doubt that adrenaline constricts the arterioles of the liver, and leads then to a rise of pressure in the hepatic artery and an increase in the arterial inflow, the general blood-pressure being also raised. This is followed by a period of lessened inflow, although the hepatic pressure is still high, but the general pressure is only slightly elevated. Exceptions to this rule are explained by the fact that an injection of adrenaline does not necessarily imply that it enters the hepatic artery; it might be swept past the orifice of the artery; a similar accident in the case of arteries supplying other organs might explain unexpected results there.   W. D. H.

The Vascularity of the Liver. IX. Influence of Amyl Nitrite on the Arterial Inflow. RUSSELL BURTON-OPITZ (*Quart. J. expt. Physiol.*, 1912, 5, 325—328).—Inhalation of amyl nitrite causes a fall of general arterial pressure, but also causes a local change in the liver circulation. The fall of pressure in the hepatic artery is proportional to the general fall. On discontinuing the inhalation the pressure returns very slowly to normal. The arterial inflow is directly proportional to the systemic pressure, and the local changes are attributed wholly to the general effect.   W. D. H.

The Vascularity of the Liver. X. The Influence of Adrenaline on the Venous Inflow. RUSSELL BURTON-OPITZ (*Quart. J. expt. Physiol.*, 1912, 5, 329—342).—Evidence is adduced that the liver possesses two separate motor mechanisms, one in the terminals of the hepatic artery, and the other in the radicles of the portal vein, both of which are stimulated by adrenaline.   W. D. H.

Metabolism Experiments in the Administration of Atophan. WITOLD SKORCZEWSKI and J. SOHN (*Chem. Zentr.*, 1912, ii, 1381; from *Zeitsch. expt. Path. Ther.*, 1912, 11, 254—263).—Experiments on normal persons and on sufferers from gout show that the administration of atophan causes an increase in the output of uric acid, which, however, falls off with subsequent doses, more purine bases being discharged. An alteration in the functions of the kidneys is presumed, for a retention of chlorides immediately follows the administration. The atophan urine always gives the diazo-reaction, which becomes weaker after several doses; it also gives the phenol reaction with bromine water, a dirty rose-coloured precipitate with Millon's reagent, a yellow precipitate with phosphotungstic acid, and a green colour with a mixture of ammonium sulphate and ammonia.

                                                        J. C. W.

Why Does Atophan Increase the Excretion of Uric Acid? WITOLD SKÓRCZEWSKI (*Chem. Zentr.*, 1912, ii, 1679; from *Zeitsch. expt. Path. Ther.*, 1912, 11, 501—507. Compare preceding abstract),—

The action of atophan is presumed to be an oxidation disturbance, of which the interference in the degradation of uric acid is a special case. This affords an explanation of the variations in uric acid values, the increase in neutral sulphur, and the appearance of the diazo-reaction in atophan urine. J. C. W.

The Formation of Phenol from *p*-Cresol in the Organism of the Dog. MAX SIEGFRIED and R. ZIMMERMANN (*Biochem. Zeitsch.*, 1912, 46, 210—224).—In view of Baumann's conceptions as to the degradation of tyrosine in the organism through *p*-cresol and *p*-hydroxy-benzoic acid to phenol, the effect of the administration of *p*-cresol was investigated, and it was found to yield phenol; 32—48% of the phenolic substances administered were recovered in the urine, of which 23—46% was in the form of phenol. Various modifications in the technique of phenol and cresol estimation are given, chiefly with regard to the method of bromination, and the addition of sufficient alkali before evaporating the urine to prevent loss of phenol.

S. B. S.

Formation of Glycine in the Body. II. ALBERT A. EPSTEIN and SAMUEL BOOKMAN (*J. Biol. Chem.*, 1912, 13, 117—132).—Free leucine does not yield glycine, although it undergoes decomposition in the body. When benzoyl-leucine is given with benzoic acid, the output of hippuric acid is much greater than the leucine alone allows. Phosphorus poisoning causes no increased production of glycine or hippuric acid. Phosphorus plus benzoic acid has also no such effect unless the animal is fasting; then the increase must be due to massive disintegration of protein. Much of the glycine liberated on feeding with benzoic acid must be the result of a synthesis in the body. W. D. H.

Tolerance to Nicotine. WALTER E. DIXON and W. E. LEE (*Quart. J. expt. Physiol.*, 1912, 5, 373—382).—A person tolerant to nicotine may be so because nicotine is not absorbed, but this is unlikely. A second explanation may be that it is more readily destroyed by the tissues. The present experiments were made on rabbits, and in thirteen out of sixteen experiments, tolerance was established, the drug being injected under the skin, or into the blood-stream. The analyses of the tissues show that the second explanation given above is correct, but that all the cells of the body do not possess the power of destroying nicotine in equal measure: the liver is the most effective. Evidence is adduced that the destruction is probably oxidative and due to the action of an enzyme. W. D. H.

The Oxidation of *p*-Phenylenediamine by Animal Tissues. FR. BATTELLI and (Mlle.) LINA STERN (*Biochem. Zeitsch.*, 1912, 46, 317—342).—It is shown in investigations of the oxidative functions of tissues that the *p*-phenylenediamine reaction is better than the indophenol reaction. All tissues can oxidise this substance. The amount of oxygen consumed was in most cases measured, and it was found that in the accessory respiration of the tissues the amount consumed

was the sum of that used up by the tissues, when without the reagent plus the amount necessary to oxidise the reagent. In the primary respiration, on the other hand, the p-phenylenediamine oxidation partly replaced the tissue respiration. The oxidation is most intensive in the heart, red muscles, liver and kidney, and much less in the pancreas, spleen, and lungs. With the exception of the pancreas, the tissues maintain their oxidative capacity for a long time after death. Under similar conditions of experiment, most tissues use up the same amount of oxygen for oxidising p-phenylenediamine as they do for succinic acid; the brain, however, uses up more. In muscles and liver, no more oxygen is used up if both substances are present than if they are present alone. The blood is an energetic oxidiser, but not the serum, and the action appears to be due mostly to the hæmoglobin, as in the blood of some animals, the oxidative capacity remains after heating to 60°, or treatment with pancreatin. This is not even lost after heating the blood with mineral acids. An aqueous extract of liver inhibits the oxidative capacity of the blood, and the inhibitory action is not destroyed by warming to 60°. Blood has no appreciable oxidative action on succinic acid.   S. B. S.

The Influence of Various Factors on the Oxidation of p-Phenylenediamine by Animal Tissues. FR. BATTELLI and (Mlle.) LINA STERN (*Biochem. Zeitsch.*, 1912, 46, 343—366).—Small amounts of acid or alkali inhibit oxidation. There is no marked optimal temperature of reaction between 30° and 50°, but the action is lost by heating tissues to 60° for ten minutes. In medium concentrations, salts accelerate the reaction, exerting an inhibitory action at higher concentrations. Up to a certain limit the rate of oxidation increases with an increase of the concentration of the p-phenylenediamine. The oxydase is not washed out from the tissues by water, and the washed tissues still contain the oxydase. In oxygen, the reaction is more energetic than in air. The oxydase is destroyed by treating the tissues with alcohol or acetone, or with weak solutions of mineral acids. Aqueous extracts of tissues oxidise in presence of hydrogen peroxide, and this function is not lost on heating. The washed residue of muscular tissue will not oxidise in the presence of the peroxide after heating to 60°. Treatment of tissue with pancreatin diminishes the oxidative capacity. Both fresh and heated pancreatin increase the oxidative capacity of the vegetable polyphenoloxydases. Catalysts accelerating the oxidation of p-phenylenediamine and succinic acid are distinguishable from other oxydases by the facts that they are not dissolved out by water, and are destroyed by alcohol, acetone, or trypsin. With the exception of those of the brain, the catalysts appear to be identical.   S. B. S.

Pharmacology of Picrotoxin, Picrotin, and Picrotoxinin. ALFREDO CHISTONI (*Chem. Zentr.*, 1912, ii, 371—372; from *Arch. Farmacol. sperim.*, 1912, 13, 220—240).—Picrotoxin and picrotoxinin, in concentration 1 in 2000, reduce the tone and the amplitude of the contractions of smooth muscle, but in concentration 1 in 10,000 they increase the amplitude and diminish the number of contractions,

and either do not influence or slightly increase the tone of smooth muscle ; picrotin is inactive.

All three substances, in a concentration of 1 in 2000, slightly increase the tone of striped muscle.

The frequency and contraction of the amphibian heart are affected by picrotoxin and picrotoxinin, due to their action on the muscle ; picrotin is inactive.

Picrotoxin and picrotoxinin intravenously injected in dogs reduce the pulse and increase the blood pressure, due to stimulation of the pneumogastric and the vasomotor centres.

All three substances (1 in 2000—4000) still the isolated hearts of cats and rabbits, but this effect ceases when the poisons are removed. In a concentration of 1 in 80,000, picrotoxin at first quickens and then slows the heart's action, and these effects are not inhibited by the previous application of atropine. Picrotoxinin (1 in 80,000) at first strengthens and quickens the heart's action by its effect on the vagus, but finally stills the heart by direct action on the muscle fibres. Picrotin (1 in 40,000) accelerates the heart-beats and reduces the strength of the pulse. T. A. H.

The Poisonous Nature of Methyl and Ethyl Alcohols. ALEXANDER LANGGAARD (*Chem. Zentr.*, 1912, ii, 1382—1383; from *Berl. klin. Woch.*, 1912, 49, 1704).—Methyl alcohol is more poisonous than ethyl alcohol when taken in repeated small quantities, but ethyl alcohol is much more dangerous when taken in a single large dose. J. O. W.

Hæmolytic Substances obtained from Serum, and the Vitellus of Egg, Submitted to the Action of Venoms. C. DELEZENNE and (Mlle.) S. LEDEBT (*Compt. rend.*, 1912, 155, 1101—1103. Compare *ibid.*, 1911, 152, 790; 153, 81).—Cobra venom acts on the serum of horse blood or the vitellus of egg, giving rise, by diastatic action of the venom on the lecithin, to *hæmolysin*, which differs from lecithin in that it is soluble in water and insoluble in ether, and its molecule does not contain any unsaturated fatty acids (oleic acids). It resembles lecithin in its solubility in alcohol.

In the case of the serum the venom-serum mixture attains a maximum hæmolytic power, which then decreases until the mixture is inactive. At the same time a very fine precipitate of calcium soaps (palmitate and stearate) is produced. This diminution in activity, which is peculiar to serum, corresponds with further decomposition of the hæmolysin, and if the serum is dialysed prior to addition of the venom, the second stage in the action does not occur, and it behaves in the same manner as the vitellus of egg. The liquid resulting from the dialysis of the serum produces this secondary effect on addition to a venom-vitellus mixture. W. G.

Chemistry of Vegetable Physiology and Agriculture.

A Hygienic Pipette for Bacteriological and Chemical Work. SERGEI TSCHACHOTIN (*Centr. Bakt. Par.*, 1912, i, 67, 319—320) —The pipette is intended to facilitate the removal of liquid cultures of pathogenic organisms, volatile poisonous compounds, or liquids above flocculent precipitates. A double-bored rubber cork is cut transversely, and between the two parts an ordinary rubber cap, such as is used for closing bacterial tube-cultures, is interposed and the three cemented together. Holes are made through the rubber cap with a hot needle, and two tubes are introduced: (*a*) a short straight one projecting slightly above and below the cork; (*b*) a siphon tube having the longer arm through the cork. A test-tube, having a diameter slightly larger than that of the rubber cork, is used as receiver, and closed by means of the flange of the rubber cap. The short arm may then be placed in the liquid to be pipetted off, and the cork of the pipette depressed slightly into the tube; the short glass tube is then closed by the fore-finger and the cork raised slightly. By this means a sufficient vacuum is created in the tube to cause the liquid to siphon over, and the flow is stopped by raising the short arm out of the liquid.
                                                            H. B. H.

Detection of Chitin in Bacteria. A. VIEHOEVER (*Ber. Deut. botan. Ges.*, 1912, 30, 443—452).—Chitin was found to be present in a number of bacteria, and the occurrence of glucosamine in bacterial material is attributed chiefly to the abundant presence of chitin rather than to glucoproteins.
The results are of interest in removing a supposed difference between fungi and bacteria. That fungi contains chitin has been known for a long time.   N. H. J. M.

Gas Metabolism of Bacteria. I. Fermentation of Dextrose by Bacillus coli, B. typhosus, and Bacterium welchii. FREDERICK G. KEYES and LOUIS J. GILLESPIE (*J. Biol. Chem.*, 1912, 13, 291—304). —The evolution of gas accompanying bacterial growth on media containing dextrose was studied by an exact method. Dextrose peptone media yield with *B. coli* more carbon dioxide than hydrogen on anaerobic fermentation; on a medium of ammonium lactate, di-sodium phosphate, and dextrose, nearly equal volumes of the two gases are obtained, the mean value of CO_2:H_2 being 1·06. This ratio is raised by the presence of oxygen, and by increase of phosphate. With *B. typhosus* the ratio is never below 19; with *Bacterium welchii* it is 1·48.   W. D. H.

Gas Metabolism of Bacteria. II. The Absorption of Oxygen by Growing Cultures of Bacillus coli and Bacterium welchii. FREDERICK G. KEYES and LOUIS J. GILLESPIE (*J. Biol. Chem.*, 1912, 13, 305—310).—For both micro-organisms the absorption of oxygen

simulates a unimolecular reaction, but the respiratory quotients are widely different. With varying oxygen pressures the ratio $CO_2 : H_2$, varies enormously for *B. coli*, but only slightly for *Bact. welchii.*

W. D. H.

Activation of Certain Processes of Microbic Oxidation by Uranium Salts. HENRI AGULHON and R. SAZERAC (*Compt. rend.*, 1912, **155**, 1186—1188).—A further study of the influence of uranyl acetate on *Mycoderma aceti* (compare A., 1912, ii, 973) and a comparative trial of the influence of uranyl nitrate and uranyl acetate on the sorbose bacteria. In the case of the acetic acid ferment, 1 part of uranyl acetate per 1000 gives an increase of 57% in the acid production, and even at a dilution of 1 in 100,000 an increase is shown at the end of seven days. With the sorbose bacteria, uranyl nitrate increases the rate of oxidation up to concentrations of 1 in 5000, but stops all fermentation at 1 in 1000. At all concentrations the acetate has a more favourable influence than the nitrate, and 1 part of the acetate in 10,000 produces an increase yield of 76%.

W. G.

Action of Infinitesimal Doses of Different Alkaline Substances, Fixed or Volatile, on the Vitality of Microbes. AUGUSTE TRILLAT and M. FOUASSIER (*Compt. rend.*, 1912, **155**, 1184—1186).—A study of the effect of adding minute quantities of various alkalis and organic bases to distilled water, to which is then added a drop of dilute, microbic, aqueous emulsion, containing no nutrient medium. The results, expressed in numbers of colonies formed, are given for the organism *M. prodigiosus*. With pure water there is slight growth for twenty-four hours and then the organism dies. Death is immediate with sodium hydroxide until a dilution of 1 in 50,000 is reached, and it is only in the case of ammonia, at dilutions of 1 in 50,000 and higher, that there is any marked increase in the number of colonies. With organic bases at higher orders of dilution (1 in 250,000) the number of colonies formed is greater with fatty amines than ammonia, and still greater with aromatic amines, although even here death ensues after fifteen days. The addition of traces of putrefactive gases to the distilled water allows cultivation to proceed even after three months.

W. G.

Putrefaction with Special Reference to the Proteus Group. LEO F. RETTGER and CLYDE R. NEWELL (*J. Biol. Chem.*, 1912, **13**, 341—346).—Putrefaction is taken to mean decomposition of protein with the production of malodorous substances. The power to bring this about has been attributed to various members of the *Proteus* group acting anaerobically. The present experiments do not confirm this.

W. D. H.

The Influence of Organic Acids on the Fermentation by Yeast. FRITZ JOHANESSOHN (*Biochem. Zeitsch.*, 1912, **47**, 97—117).— Formic acid and its higher homologues accelerate, in sufficiently dilute solutions, the rate of fermentation by yeast. The optimal action for each acid lies at the same molecular concentration. The smallest

quantities of the acids which stop fermentation do not kill the yeast. The stoppage of fermentation depends on the concentration of the acid and not on the absolute quantity present. The relationship between this concentration and the quantity of yeast is not a simple proportional one, but can be represented by the equation of a parabola. No appreciable adsorption of acids by yeast takes place. The essential action of acids is to be ascribed, not to the ions, but to the whole undissociated molecule.   S. B. S.

The Mechanism of Alcoholic Fermentation. ALEXANDER VON LEBEDEV (*Biochem. Zeitsch.*, 1912, 46, 483—489).—A reply to the criticisms of Harden and Young (A., 1912, ii, 670).   S. B. S.

The Mechanism of Alcoholic Fermentation. II. ALEXANDER VON LEBEDEV and N. GRIAZNOV (*Ber.*, 1912, 45, 3256—3272. Compare A., 1911, ii, 816, 1122).—Pure glyceraldehyde is fermented by extract of dried yeast directly to carbon dioxide and alcohol. Hexosephosphoric ester is not formed as intermediate compound as in the case of the fermentation of dihydroxyacetone.

It is further shown that during the fermentation of sugar by yeast extract, acetaldehyde is not reduced to alcohol; on the other hand, in the absence of sugar, yeast extract is able to reduce acetaldehyde to alcohol. This reduction is effected by an enzymatic process.

It is considered that during fermentation hexose is hydrolysed to two trioses, one of which, glyceraldehyde, loses hydrogen, forming pyruvic acid, which undergoes rearrangement immediately and breaks down into acetaldehyde and carbon dioxide (compare Neuberg, A., 1911, ii, 976, 1019, 1020). Methylglyoxal hydrate is possibly an intermediate product (Neuberg and Kerb, A., 1912, ii, 973); preliminary experiments indicate that methylglyoxal is fermentable by yeast juice.

The decomposition of hexose into two molecules of triose is regarded as a reversible reaction; it will proceed when part of the triose is withdrawn as hexosephosphate, so that this last compound acts as a regulating factor. The following complete scheme is suggested for fermentation :

$$4C_6H_{12}O_6 = 8C_3H_6O_3.$$

Glyceraldehyde.	Dihydroxyacetone.

$$4C_3H_6O_3 - 4H_2 = 4C_3H_4O_3$$
$$4C_3H_4O_3 = 4C_2H_4O + 4CO_2$$
$$4C_2H_4O + 4H_2 = 4C_2H_7 \cdot OH$$

$$4C_3H_6O_3 + 4RHPO_4 =$$
$$4C_3H_5O_3RPO_4 + 4H_2O$$
$$= 2C_6H_{10}O_4(RPO_4)_2 + 4H_2O$$
$$= 2C_6H_{12}O_6 + 4RHPO_4$$

$$2C_6H_{12}O_6 = 4C_3H_6O_3, \text{ etc.}$$
E. F. A.

Influence of Pressure on Alcoholic Fermentation. LÉON LINDET and L. AMMANN (*Bull. Soc. chim.*, 1912, [iv], 11, 953—956).—Regnard has shown already that under a pressure of 600 atmospheres yeast still ferments sugar solutions. In the present paper it is demonstrated that under such pressures as may occur in practice in fermenting liquids with yeast in closed vessels, the reproduction of

yeast and the fermentation go on at the same rate as under atmospheric pressure, although when the experiments are conducted under such conditions that the air is not renewed, fermentation and the multiplication of the yeast-cells take place more slowly, although the same production of carbon dioxide and alcohol is eventually reached.

T. A. H.

Is Ethyl Alcohol Produced by Yeast Fermentation in Absence of Sugar? CARL NEUBERG and JOHANNES KERB (*Chem. Zentr.*, 1912, ii, 1299—1300; from *Zeitsch. Gärungsphysiol. Mykologie*, 1912, 1, 114—120).—Since pyruvic acid is easily attacked by yeast with the formation of acetaldehyde (A., 1911, ii, 1019) it was expected that the ferment alone might be able to carry the reduction further. No alcohol could be found, however, but in the presence of sugar, much less aldehyde was formed than the amount of pyruvic acid destroyed would warrant. It seemed, therefore, that in normal alcoholic fermentation, a substance is produced which can reduce pyruvic acid or acetaldehyde to alcohol. Formic acid suggested itself, but was found to be without influence. Glycerol, however, had the effect of largely diminishing the output of acetaldehyde.   J. C. W.

The Primary Transformation of Hexoses by Alcoholic Fermentation. HANS VON EULER and TH. BERGGREN (*Chem. Zentr.*, 1912, ii, 1383—1384; from *Zeitsch. Gärungsphysiol. Mykologie*, 1912, 1, 203—218).—The addition of yeast extract to living yeast expedites fermentation by 100%, and the difference, ΔC, between the change in optical rotatory power and the carbon dioxide developed (compare A., 1912, ii, 377) is increased by 20%. Assuming that fermentation proceeds in two stages, hexose $\longrightarrow$ intermediate product and intermediate product $\longrightarrow$ alcohol and carbon dioxide, it follows that, if the extract contains only one co-enzyme the first stage will be accelerated, but if there is a co-enzyme in the extract appropriate to each stage, then the two reactions will be unequally accelerated according to the relative amounts of the co-enzymes. Sodium nucleate also increases the activity of living yeast.   J. C. W.

The Effect of Phosphates on the Work of the Proteolytic Enzymes in Yeast. NICOLAUS IWANOV (*Chem. Zentr.*, 1912, ii, 1384—1385; from *Zeitsch. Garüngsphysiol. Mykologie*, 1912, 1, 230—252).—The action of antiproteolytic by-products in yeast fermentation may be overcome by the addition of acid phosphates. Experiments with dead yeast cells (hefanol) show that the decomposition of albumin increases with the concentration of potassium dihydrogen phosphate, and that this increase is independent of temperature. By decreasing the volume of liquid, or by the addition of autolysis products, the action is still further increased, whereas leucine and tyrosine do not influence the process, but dipotassium hydrogen phosphate hinders it.

The proteolytic enzyme may be partly extracted from hefanol by means of water. When heated to 80°, it becomes inactive, but the addition of potassium dihydrogen phosphate revives its activity. It

seems that this salt is able to regenerate the peptase and to promote its action. J. C. W.

Comparative Influence of Potassium, Rubidium, and Cæsium on the Development and Sporulation of Aspergillus niger. BENJAMIN SAUTON (*Compt. rend.*, 1912, 155, 1181—1183).—*Aspergillus niger* was cultivated on Raulin's liquid in the presence of equivalent amounts of potassium, rubidium, and cæsium as chlorides, and the crops weighed after four days at 37°. Potassium causes an enormous increase in the crop, which is diminished by 50% on replacing the potassium by rubidium, whilst cæsium is not a nutrient substance for the organism. In a mixture of the chlorides, *Aspergillus niger* fixes the potassium before the rubidium and cæsium, thus forming a means of freeing the two latter from the last traces of the former metal. Potassium plays an important part in the sporulation, although in the absence of zinc this could not be conclusively demonstrated. On substituting rubidium or cæsium for potassium no spores are formed. W. G.

The Scission of a- and β-Methylglucoside by Aspergillus niger. ARTHUR W. DOX and RAY E. NEIDIG (*Biochem. Zeitsch.*, 1912, 46, 397—402).—*Aspergillus niger* acts on the two glucosides in exactly the opposite way to that in which yeast acts, for it readily hydrolyses the β-form (100% within six days), whereas it acts only slowly on the a-form, hydrolysing only 8% in twenty days. No capacity of adaptation of the ferment to the a-form could be demonstrated. S. B. S.

The Behaviour of Moulds (Aspergillus niger and Penicillium crustaceum) towards Phytin. M. A. JEGOROV (*Zeitsch. physiol. Chem.*, 1912, 82, 231—242).—The moulds mentioned grow well in a solution of phytin, and assimilate its phosphorus, especially in the presence of sucrose and peptone or glycerol. They split off phosphoric acid in high measure from the phytin. W. D. H.

Decomposition of Carbamide, Uric Acid, Hippuric Acid, and Glycine by Moulds. ALEXANDER KOSSOWICZ (*Bied. Zentr.*, 1912, 41, 791—792; from *Zeitsch. Garüngsphysiol. Mykologie*, 1912, 1, 60—60). —Pure cultures of the following moulds were found to assimilate urea, uric acid, hippuric acid, and glycine under sterilised conditions: *Botrytis lassiani*, *Aspergillus niger*, *Isaria farinosa*, a *Fusisporium*, *Mucor Boidin*, and *Phytophthora infestans*. *Penicillium brevicaule* and *P. crustaceum* utilise urea, uric acid, and glycine, whilst *Cladosporium herbarum* and *Aspergillus glaucus* only utilised urea and uric acid as sources of nitrogen. N. H. J. M.

The Apparent Respiration of Dead Cells in the Reduction of Pigments. OTTO MEYERHOF (*Pfluger's Archiv*, 1912, 149, 250—274).—Neutral and weakly alkaline acetone yeast possesses a measurable power of taking up oxygen, and this is increased in the presence of methylene-blue. In the presence of dead cells, reduction

of methylene-blue occurs also, but it occurs also if the dead cells are absent. It is, therefore, not due to anything of the nature of vitality. In one living animal cell, the egg of the sea-urchin, dissolved oxygen is present.　W. D. H.

The Action of Uranium on the Plant Cell. C. ACQUA (*Chem. Zentr.*, 1912, ii, 1471 ; from *Arch. Furmacol. sperim.*, 1912, 14, 81—84).—Dilute solutions of uranium salts (1 : 20,000 to 1 : 40,000) are absorbed by the cells of the roots of higher plants, where they hinder the division of the nuclei, and, consequently, the growth. The cells of the green parts are less permeable to uranium salts, and are therefore scarcely injured. Thorium and manganese salts have a similar but much smaller effect.　J. C. W.

Absorption of Aniline Dyes in Living Plant Cells. E. KUSTER (*Bied. Zentr.*, 1912, 41, 763—764; from *Jahrb. wiss. Bot.*, 1911, 50, 261).—It is shown that a considerable number of dyes, insoluble in fats, are abundantly taken up by plant cells. Overton's lipoid hypothesis regarding the nature of the outer layer of protoplasm is, therefore, insufficient, whilst Ruhland's opinion that there is no relation between the diffusibility of dyes and their penetration into plant cells is incorrect.　N. H. J. M.

The Physical Character of Bio-electrical Differences of Potential. REINHARD BEUTNER (*Biochem. Zeitsch.*, 1912, 47, 73—93). —The difference of potential at the contact surfaces—part of plant/aqueous solution of an electrolyte—can be altered in the sense that increasing dilution of the electrolyte makes the solution more positive. The change can be expressed by the following equation:

$$\text{Pot. diff. } 1 - \text{Pot. diff. } 2 = 58 \log \frac{c_1}{c_2} - 58 \log \frac{1 + \sqrt{1 + 10^6 m^2 c_1{}^2}}{1 + \sqrt{1 + 10^6 m^2 c_2{}^2}}$$

where

$$\log \frac{1}{m} = \frac{\text{Limiting value of potential difference} - \text{Pot. diff. for } c = n/500}{58}.$$

The method of arriving at these equations is given, and also an experimental verification of the same. The biological significance is also discussed.　S. B. S.

Sterile Cultures of a Higher Plant. Assimilation of Nitrogen as Ammonia and as Nitrates. IVAN SCHULOV (*J. exper. Landw.*, 1912, 13, 200—205 (in Russian), 205—206 (German Abstr.). Compare Hutchinson and Miller, A., 1909, ii, 923).—The results of sand culture experiments, under sterilised conditions, showed ,that nitrogen in the form of ammonium sulphate is assimilated by maize plants. It is also shown that the availability of phosphorite is considerably increased by the employment of ammonium nitrate, and that ammonium nitrate overcomes the injurious action of ammonium sulphate.
N. H. J. M.

Localisation and Function of Potassium in Plants. TH. WEEVERS (*Bied. Zentr.*, 1912, 41, 764—765 ; from *Rec. trav. bot. Néerland.*, 1911, 8, 289—332).—By means of Macallum's reagent

(sodium cobaltinitrate with ammonium sulphide and glycerol) it was found that potassium is present in all parts of *Thallophytes*, whilst negative results were obtained with the pollen grains of crocus and tulips. The greatest amount of potassium in *Phanerogams* was found in the young, embryonal tissues rich in plasma, and in the parenchyma of leaves, seeds, roots, and stems.

The conclusion is drawn that potassium takes part in the production of proteins. Its absence in the chlorophyll is opposed to the theory of Grafe and Stoklasa, that it takes part in the process of assimilation.   N. H. J. M.

Chlorogenic and Saccharic Acids in Latex. K. Gorter (*Rec. trav. chim.*, 1912, 31, 281—286).—The colour reactions with ferric chloride which de Jong and Tromp de Haas (A., 1904, ii, 762) have shown to be characteristic of the latex of certain plants resemble the reactions with the chlorogenic acid obtained from coffee (A., 1908, i, 186). A delicate test for this acid is now described. It consists in boiling the suspected substance with dilute hydrochloric acid for an hour, extracting with ether, and shaking the washed and not too concentrated extract with very dilute ferric chloride, when a violet coloration is produced. By this means it is shown that chlorogenic acid is present in the latex of *Ficus elastica* and of *Castilloa elastica*. It has actually been isolated from the latter substance, 300 grams of the latex yielding 0·3 gram chlorogenic acid, m. p. 208°, $[a]_D^{25} - 35·2°$. The latex of *Ficus elastica* contains, in addition, an organic magnesium salt, which has now been isolated and given the formula

$$C_6H_8O_8Mg,3H_2O.$$
The free acid has $[a]_D^{25} + 36·5°$, and gives a sparingly soluble potassium salt, which closely resembles potassium disaccharate, and a diphenylhydrazone, m. p. 210°, which is identical with that derived from *d*-saccharic acid. This magnesium salt is the first indication of the occurrence of *d*-saccharic acid in nature.   J. C. W.

The Carboxylase of Higher Plants. W. Zaleski and Elisabeth Marx (*Biochem. Zeitsch.*, 1912, 47, 184—185).—Neuberg has shown that yeast can ferment pyruvic acid with evolution of carbon dioxide. The authors now show that the addition of this acid to powdered pea-seeds causes an increase of the post-mortal production of carbon dioxide, which takes place with equal energy in air and hydrogen.   S. B. S.

Basic Constituents of Fly Agaric. E. Buschmann (*Chem. Zentr.*, 1912, ii, 613; from *Pharm. Post*, 1912, 45, 453—454).—A methyl alcohol extract of fly agaric (*Amanita muscaria*) by precipitation with phosphotungstic acid and silver nitrate yielded hypoxanthine and xanthine, the former predominating (compare Zellner, *Chemie der höheren Pilze*, 1907).   T. A. H.

The Inulin Metabolism of Cichorium Intybus (Chicory). II. The Formation and Storage of Inulin. Viktor Grafe and V. Vouk (*Biochem. Zeitsch.*, 1912, 47, 320—330. Compare A., 1912, ii, 977).—From estimations of reducing sugar and inulin in different

parts of the plant collected at different periods, the following conclusions were drawn.   The inulin is not merely a reserve material, but is intimately connected with the general carbohydrate metabolism, as it can be readily detected macrochemically in the parenchymatous cells of the leaves of young plants.   No difference in the inulin and lævulose content of leaves of plants collected in the morning and afternoon could be detected.   From this fact the conclusion is drawn that new carbohydrate is formed during the day in such quantity that an equilibrium is maintained between the lævulose and inulin.   As the development of the root progresses there is a constant increase in the inulin content, accompanied at first by a diminution of the lævulose ; the latter increases in quantity again as the roots ripen.

S. B. S.

The Organic Phosphoric Acid of Cotton-seed Meal.   R. J. ANDERSON (*J. Biol. Chem.*, 1912, 13, 311—324).—The organic phosphorised substance from cotton-seed meal is probably either phytin or an isomeride ; this is to be ascertained by further work.

W. D. H.

Pigments of the Fucoideæ.   HARALD KYLIN (*Zeitsch. physiol. Chem.*, 1912, 82, 221—230).—The fucoideæ contain carrotene and a crystalline, yellow pigment probably identical with xanthophyll.   They further contain a yellow pigment, phycoxanthin, which differs from xanthophyll in being soluble in light petroleum.   E. F. A.

Presence of Gentiopicrin, Gentianose, and Sucrose in the Fresh Roots of Gentiana Asclepiadea.   MARC BRIDEL (*Compt. rend.*, 1912, 155, 1164—1166).—The author has isolated and characterised gentiopicrin, gentianose, and sucrose from the fresh roots of *Gentiana Asclepiadea*, and has obtained indications of the presence of another carbohydrate, hydrolysable by invertin.   W. G.

The Constituents of Ipé tabaco Wood (Bignonia tecoma). OTTO A. OESTERLE (*Chem. Zentr.*, 1912, ii, 1666—1667 ; from *Schweiz. Woch. Chem. Pharm.*, 1912, 50, 529—532).—In order to investigate the nature of Lee's tecomin (T., 1901, 79, 284), the alcoholic extract of *B. tecoma* wood has been freed from resinous matter by means of benzene and light petroleum, leaving a mixture which was partly soluble in boiling sodium carbonate solution.   The soluble substance crystallised in yellow needles or leaflets, m. p. 142—143°, soluble in alkalis and alkali carbonates with intense red colours which disappeared on reduction, but soon reappeared in the air.   Tecomin is possibly identical with lapachol.   From the substance which remained undissolved by sodium carbonate, light yellow needles, m. p. 242°, were obtained.   J. C. W.

Variations of the Fatty Matters, Sugars, and Saponin during the Maturation of Seeds of Lychnis Githago.   (Mlle.) MARIE KORSAKOV (*Compt. rend.*, 1912, 155, 1162—1164).—The fatty matters, sugars, and saponin have been estimated in the seeds of *Lychnis Githago*

at three stages in their development: (*a*) just after flowering, when young and white; (*b*) further advanced but still white; (*c*) almost ripe and black. The results show a marked decrease in the content of fatty matters and sugars, reducing and non-reducing, and an increase in the saponin content with advance in development. The young seeds only contain traces of saponin, and the amount of saponin in the other organs of the plant being practically nil, it seems that the glucoside must be formed in the seed itself.   W. G.

Presence of Gentiopicrin in Swertia perennis. MARC BRIDEL (*Compt. rend.*, 1912, 155, 1029—1031; *J. Pharm. Chim.*, 1912, [vii], 6, 481—484).—*Swertia perennis* contains the glucoside gentiopicrin, which can be isolated in the pure state and hydrolysed by emulsin (compare Bourquelot and Bridel, A., 1910, ii, 234) There are also indications of the presence of a carbohydrate, which is only very slowly hydrolysed by emulsin.   W. G.

Occurrence of Trehalose, Vanillin, and *d*-Sorbitol. EDMUND O. VON LIPPMANN (*Ber.*, 1912, 45, 3431—3434).—After exposure to a sudden sharp frost in July, the flowers of some blooming rushes, *Carex brunescens*, growing in a sheltered spot, were observed to be covered with minute, hard, white crusts, which proved to be hydrated trehalose, $C_{12}H_{24}O_{11},2H_2O$.

The flowers of an orchid, *Gymnadenia albida*, growing last summer on the heights above Davos, were observed by the author to have a strong odour of vanilla; vanillin was isolated from them. Under normal conditions of growth, the flowers of this orchid contain little or no vanillin.

During last year's wet summer, many fungi in the fields near Kissingen grew in enormous quantities and to prodigious size, in particular, a variety of *Boletus bovinus*, which reached the dimensions of a dinner plate. After fine weather had set in, a number of the tops of these fungi, which had been struck off by a passer-by and had partly dried, were found to be covered with a network of a crystalline substance which on examination proved to be hydrated *d*-sorbitol.

                                                    C. S.

Chemical means of Protecting Plants from Frost. N. A. MAXIMOV (*Ber. Deut. bot. Ges.*, 1912, 30, 504—416. Compare A., 1912, ii, 476).—The supposition that the protective action of the substances employed depends on the eutectic point of the solution is confirmed by the results of further experiments in which mixtures instead of single substances were used. A mixture of mannitol and potassium nitrate considerably increased the power of resisting cold, whilst the two substances, singly, have very little effect.

As regards the connexion between the protective action and the permeability of the plasma for the protective substance, it is now shown that the action takes place immediately, and that the result depends on the action of the solution on the surface of the plasma. From this it follows that the death of plants by freezing is due to injury to the surface of the plasma.   .   N. H. J. M.

Alfalfa. IV. **Enzymes Present in Alfalfa Seeds.** C. A. JACOBSON (*J. Amer. Chem. Soc.*, 1912, **34**, 1730—1740).—In continuation of the investigation of alfalfa (*Medicago sativa*) (A, 1912, ii, 80, 239, 976), a study has been made of the enzymes contained in the seeds. The results show that the seeds contain enzymes, which, like amylase and emulsin, are capable of hydrolysing starch and amygdalin respectively; an enzyme which coagulates milk, like rennin; an enzyme, which like the peroxydases, precipitates purpurogallin from a pyrogallol solution containing hydrogen dioxide, and an enzyme, resembling proteases in being able to digest casein and Witte peptone. This protease is found to be a vegetable erepsin, since it will not begin the digestion of egg-albumin, blood-serum, legumin, or conglutin, and its digestion of casein and Witte peptone is checked to some extent by the presence of egg-albumin or blood-serum. The seeds do not appear to contain invertase or lipase.   E G.

Comparative Efficiency for Growth of the Total Nitrogen from Alfalfa Grass and Corn Grain. EDWIN B. HART, GEORGE C. HUMPHREY, and F. B. MORRISON (*J. Biol. Chem.*, 1912, **13**, 133—154). —Experiments on heifers show that the utilisation of nitrogen for growth is as efficient when the source is alfalfa hay as when it is corn kernel. There was no sudden increase or decrease in the nitrogen of urine or fæces when the animals were suddenly changed from one ration to the other. The amide-nitrogen, which is high in the grass, is therefore not valueless. The effect on milk production will be treated later. In growing heifers, the creatinine output rises with increased storage of nitrogen.   W. D. H.

Observations on the Action of Fluorine in Nature. UGO ALVISI (*Gazzetta*, 1912, **42**, ii, 450—452).—The author confirms the presence of fluorine in wheat (when ripe) and in human teeth. He suggests the employment of calcium silicofluoride as a manure.
                                                                    R. V. S.

Reducing Substances Present in Fresh Sugar Beets. Their Influence on the Direct Estimation of Sucrose in the Beet. HENRI PELLET (*Bull. Assoc. chim. Sucr. Dist.*, 1912, **30**, 239—253).— Freshly harvested sugar beets always contain a small quantity of reducing sugar, amounting to 0·05—0·27 gram per 100 c.c. of the sap. This amount is independent of the initial richness of the beet in sucrose, and does not vary in different parts of the same beet. The estimation is made in the sap clarified by treatment with neutral lead acetate; basic lead acetate precipitates some of the reducing sugar. Beets of inferior quality contain 2—2·5 grams of reducing sugar per 100 c.c of sap. Beets stored in silos lose some of their sucrose, but the amount of reducing sugar does not increase. Beets damaged during harvesting or transport contain 0·3—0·35 gram of reducing sugar; in sickly beets the quantity increases to 0·4—0·5 gram per 100 c.c. of sap.

Reducing sugar is not formed during diffusion. The amount arising

during the processes of manufacture is very small when proper care is exercised.

The presence of this reducing sugar renders the polarimetric estimation of the sucrose in the beet-juice inaccurate.   E. F. A.

Sesame Cake. ACH. GRÉGOIRE and EM. CARPIAUX (*Bull. Soc. chim. Belg.*, 1912, **26**, 479—485).—A number of samples of sesame cake have been examined with respect to the content of pure ash, lime, fat, acidity of fat, and oxalic acid. The results show great variations in the composition of the commercial products.

The pure ash contains, as a mean value, 34·5% of lime, the extreme values being 28·4% and 39·8% respectively. This determination may be employed for controlling the purity of sesame cake, since the great majority of other seeds yield an ash relatively poor in lime. Sesame cake, free from oil and earth, contains an average of 1·99% anhydrous oxalic acid, the individual determinations varying between 1·44% and 2·96%. This value is not sensibly altered when the oil becomes rancid. Free oxalic acid could not be detected.   H. W.

The Black Earths of the Valley of l'oued R'Dom in Morocco. G. GIN (*Compt. rend.*, 1912, **155**, 1166—1167).—An account of a black arable earth from a fertile valley traversed by l'oued R'Dom. A description of the earth and results of chemical analyses are given. It is found to support vegetation even in the warm, dry months, and this is supposed to be due to the presence of a trihydrated aluminium oxide in the clay, which supplies the necessary water during the dry months, and recoups itself at the next wet season. The black colour is due to an amorphous humic substance, which is partly soluble to a brown solution in potassium hydroxide.
          W. G.

Agronomic Study of Manganese. P. NOTTIN (*Compt. rend.*, 1912, **155**, 1167—1169).—A study of the behaviour of different soils towards soluble manganese salts. Soil has the power of rendering the manganese insoluble and fixing it, the constituents of the soil, however, having different absorbent powers. Silica and humus play no part in the manganese fixation. Chalk produces fixation of the manganese by interchange of the calcium and manganese. Natural clay also has a marked absorbent power, independent of the lime present.
          W. G.

Nitrolim and its Decomposition in the Soil. III. C. J. MILO (*Chem. Zentr.*, 1912, ii, 1393; from *Med. Proefstat. Java-Suikerind*, 1912, 601—634. Compare A., 1912, i, 16).—Nitrolim is hygroscopic, and absorbs water and carbon dioxide with liberation of nitrogen. The calcium cyanamide decomposes into cyanamide and carbamide, which, with the help of micro-organisms, gives rise to ammonium carbonate. In soils which are only slightly absorptive, the calcium cyanamide gives basic salts and cyanamide, and further decomposition proceeds very slowly.   J. C. W.

Organic Chemistry.

Purification of Saturated Hydrocarbons by means of Potassium Permanganate. NICOLAI M. KISHNER (*J. Russ. Phys. Chem. Soc.*, 1912, 44, 1748—1753).—Saturated hydrocarbons, when prepared by the reduction of their halogen derivatives, are usually contaminated with unsaturated hydrocarbons, and the same is the case with trimethylenic hydrocarbons prepared by Gustavson's method. The removal of these impurities is an easy matter when the saturated hydrocarbons are stable to concentrated sulphuric acid or to fuming nitric acid; but in some cases the unsaturated hydrocarbons are converted into saturated ones by these reagents, and in certain others the carbonatom skeleton undergoes isomerisation.

The author has investigated the efficacy of potassium permanganate as a means of purification in these exceptional instances. The results show that the complete removal of small admixtures of the unsaturated compounds in this way is very difficult, and is accompanied by the loss of much of the saturated hydrocarbons. As the concentration of the unsaturated hydrocarbon in the mixture diminishes, its rate of oxidation decreases, until finally it may become less than that at which the saturated compound oxidises; thus a mixture containing 15 parts of menthane and 5 parts of menthene is converted into one containing 11·5 and 2·5 parts respectively by one oxidation, these amounts becoming 7·2 and 0·8, and 3·7 and 0·3 after successive oxidations. Somewhat similar results are obtained with mixtures of menthane and limonene.   T. H. P.

Fractional Distillation of Coal. LÉO VIGNON (*Compt. rend.*, 1912, 155, 1514—1517).—The author has distilled various samples of coal at successive temperatures of 400°, 600°, 850°, 1000° and 1200°, and analysed the gaseous mixtures evolved at these temperatures. The results show (1) that the unsaturated hydrocarbons (acetylene, ethylene, etc.) almost all pass over below 600° and disappear entirely at higher temperatures; (2) methane and its homologues are very abundant (60—80% of total gas) up to 800°, after which they decrease rapidly with rise in temperature; (3) from 800—1000° hydrogen predominates, but in its turn diminishes above 1000°; (4) very high temperatures favour the formation of carbon monoxide.

Rise in distillation temperature produces an increase in the total volume of gas evolved, but a diminution in its calorific power.
                                                                 W. G.

A New Method for Determining the Position of the Double Bond. JOH. JEGOROV (*J. pr. Chem.*, 1912, [ii], 86, 521—539).—The method consists in combining the unsaturated compound with nitrogen peroxide, and heating the resulting additive compound with concentrated hydrochloric acid, whereby the molecule becomes ruptured at the position originally occupied by the double linking with the forma-

tion of two carboxylic acids : $R \cdot CH \colon CHR^1 \longrightarrow NO \cdot O \cdot CHR \cdot CHR^1 \cdot NO_2$, or $NO_2 \cdot CHR \cdot CHR^1 \cdot O \cdot NO \longrightarrow R \cdot CO_2H + R^1 \cdot CO_2H$.

The transformation of a nitrite into a carboxylic acid has been investigated in the case of amyl nitrite, which, under the influence of hydrochloric acid, yields amyl alcohol and an ester, presumably amyl valerate, the valeric acid being formed by the oxidising action of the nitrite on the amyl alcohol.

When heated with water at 160—170°, the light yellow, oily, additive compound of oleic acid and nitrogen peroxide yields pelargonic acid, ω-*nitrononane*, azelaic acid, and θ-*nitrononoic acid*. The nitro-compounds could not be isolated in a state of purity, and therefore were identified by reducing them to the corresponding amino-compounds.

θ-*Aminononoic acid*, $NH_2 \cdot CH_2 \cdot [CH_2]_7 \cdot CO_2H$, was isolated in the form of its *platinichloride* from the above mixture by distillation in steam, and reduction of the residual nitrononoic and azelaic acids with tin and hydrochloric acid.

Nonylamine is a viscid liquid, and forms a *hydrochloride* which becomes black when heated without showing a definite m. p.; the *platinichloride*, $2C_9H_{19} \cdot NH_2, H_2PtCl_6$, crystallises in golden-yellow needles.

When heated with concentrated hydrochloric acid, the additive compound of oleic acid and nitrogen peroxide yields pelargonic and azelaic acids, together with hydroxylamine.

From these results the conclusion is drawn that the additive compound consists of a mixture of two isomerides (I) and (II), which, when heated with water, undergo the transformations shown in the following scheme :

(I.) $2C_8H_{17} \cdot CH(NO_2) \cdot CH(O \cdot NO) \cdot C_7H_{14} \cdot CO_2H \longrightarrow H_2O + N_2O +$

    $2C_8H_{17} \cdot CH(NO_2) \cdot CO \cdot C_7H_{14} \cdot CO_2H \xrightarrow{H_2O} C_9H_{19} \cdot NO_2 + C_7H_{14}(CO_2H)_2$.

(II.) $2C_8H_{17} \cdot CH(O \cdot NO) \cdot CH(NO_2) \cdot C_7H_{14} \cdot CO_2H \longrightarrow H_2O + N_2O +$
$C_8H_{17} \cdot CO \cdot CH(NO_2) \cdot C_7H_{14} \cdot CO_2H \longrightarrow C_8H_{17} \cdot CO_2H + NO_2 \cdot C_8H_{16} \cdot CO_2H$.
The action of hydrochloric acid on θ-nitrononoic acid gives rise to azelaic acid : $NO_2 \cdot CH_2 \cdot [CH_2]_7 \cdot CO_2H \longrightarrow$
    $HO \cdot N \colon C(OH) \cdot [CH_2]_7 \cdot CO_2H \longrightarrow NH_2 \cdot OH + C_7H_{14}(CO_2H)_2$.
In a similar manner nitrononane yields pelargonic acid.

The above method has been applied to the determination of the position of the double linking in a number of unsaturated compounds. In all cases the unsaturated compound was allowed to combine with nitrogen peroxide in light petroleum solution at a low temperature, and the resulting oily additive compounds were heated with concentrated hydrochloric acid at 130—140°.

Undecenoic acid gave sebacic and formic acids. *iso*Oleic acid decomposes into octoic and sebacic acids, corresponding with the structure $CH_2Me \cdot [CH_2]_5 \cdot CH \colon CH \cdot [CH_2]_8 \cdot CO_2H$; erucic acid into nonoic and brassylic acids.

From the behaviour of the hexylene, prepared from mannitol, which yielded formic, acetic, butyric and valeric acids, the author draws the conclusion that the hydrocarbon consists of a mixture of two isomerides, $CHMe \colon CHPr^a$ and $CH_2 \colon CH \cdot CH_2Pr^a$.

Methoxy- and ethoxy-undecenoic acids, obtained by the action of alcoholic alkali hydroxides on the dibromide of undecenoic acid, gave results in agreement with the structure:

$$OMe \cdot CH_2 \cdot [CH_2]_7 \cdot CH:CH \cdot CO_2H.$$
The unsaturated acids from linseed oil were also examined and found to consist of a mixture of the two following compounds:

$$CHEt:CH \cdot CH_2 \cdot CH:CH \cdot CH_2 \cdot CH:CH \cdot [CH_2]_7 \cdot CO_2H.$$
$$CH_3 \cdot [CH_2]_4 \cdot CH:CH \cdot CH_2 \cdot CH:CH \cdot [CH_2]_7 \cdot CO_2H.$$
F. B.

The Theory of the Asymmetric Carbon Atom and Pasteur's Principle. ERNST MOHR (*J. pr. Chem.*, 1912, [ii], 87, 91—95).—A theoretical · paper in which the author shows that, contrary to his previous views (A., 1904, i, 1), a compound of the formula $C(dR)_2(lR)_2$, where dR and lR represent structurally identical, univalent groups of enantiomorphous configuration does not contain an asymmetric carbon atom, and is therefore incapable of existing in two enantiomorphous forms. F. B.

The Melting Point of Ethylene Dibromide. EUGEN VON BIRON ·(*Zeitsch. physikal. Chem.*, 1913, 81, 590).—Moles (A., 1912, ii, 533) states that ethylene dibromide has m. p. 9·975°. Biron has shown that when purified by repeated fractional crystallisation it has m. p. 10·012° and D_4^{20} 2·1804 (*J. Russ. Phys. Chem. Soc.*, 1908, 40, 1609). He points out that the work must be carried out in the absence of light. J. F. S.

The History of Distillation and of Alcohol. EDMUND O. VON LIPPMANN (*Chem. Zeit.*, 1913, 37, 1—2. Compare A., 1912, i, 824).—The author combats the statement attributed to Davidsohn (*Mitt. Ges. Med. Naturwiss.*, 1912, 12, 102) that the Celts first submitted fermented liquors to distillation and that the knowledge of the process passed from them to other nations. D. F. T.

Ethyl Ether by Catalysis. CHARLES BASKERVILLE (*J. Amer. Chem. Soc.*, 1913, 35, 93—96).—Sabatier and Mailhe (A., 1910, i, 294) have shown that several metallic oxides, including that of thorium, exert a catalytic action on alcohols between 300° and 350°. In the case of ethyl alcohol, the action appears to consist almost entirely of dehydration with formation of ethylene, but at a lower temperature the dehydration is said to be capable of limitation to the production of ether.

Experiments are described in which alcohol vapour was passed over pure thorium oxide at about 250°, but although the conditions specified by Sabatier and Mailhe were carefully observed, little or no ether was obtained. E. G.

Esters and Amides of the Phosphoric Acids. IV. Reaction between Esters of Metaphosphoric Acid and Uni- and Multivalent Alcohols. Synthesis of Glycero-mono- and -diphosphoric Acid. Preparation of Pure Silver Metaphosphate. KURT LANGHELD, F. OPPMANN, and E. MEYER (*Ber.*, 1912, 45, 3753—3760).—In part polemical (compare Grün and Kade, this vol.,

i, 159). When ethyl metaphosphate reacts with ethyl alcohol and benzyl alcohol, the following three products are formed :

$$PO(OEt)_2 \cdot O \cdot C_7H_7, \quad PO(OH)_2 \cdot O \cdot C_7H_7, \quad OEt \cdot PO(O \cdot C_7H_7) \cdot OH.$$
The mono- and tri-esters are obtained in molecular proportions. The same result is obtained with glycerol, in which case the excess prevents the determination of the relative proportions of the esters.

Barium glycerophosphate is obtained in stellar aggregates of small platelets containing a molecule of water, which is slowly removed on drying in a vacuum. On exposure of the anhydrous substance, $\frac{1}{2}H_2O$ is absorbed quickly and the second $\frac{1}{2}H_2O$ only slowly. The solubility in water at $220°$ is 8.4%, and approaches that of the natural product. *Barium glycerodiphosphate*, $2H_2O$, crystallises well.

To prepare pure silver metaphosphate, $(AgPO_6)_2, H_2O$, sodium ammonium phosphate is converted into metaphosphate by cautious heating in a vacuum at $320°$. About half the product is soluble in water, from which it is precipitated in crystalline form on the addition of alcohol. This product, $2NaPO_3, H_2O$, reacts with silver nitrate.

Silver metaphosphate crystallises in large octahedra. E. F. A.

The Glycerotriphosphoric Acid of Contardi. PAUL CARRÉ (*Compt. rend.*, 1912, **155**, 1520—1521*).—A reply to Contardi (compare A., 1912, i, 743), in which the author maintains that the esterification of 1 mol. of glycerol with 3 mols. of phosphoric acid gives glycerodiphosphoric acid, $C_3H_5(PO_4H_2)_2 \cdot OH$, glycerophosphoric acid, and a di-ester of the form PO_4R_2H, about 50% of the phosphoric acid remaining unaltered and no glycerotriphosphoric acid being formed.

He further maintains his views, already expressed (compare A., 1904, i, 133, 215 ; 1905, i, 184), that, on heating an equimolecular mixture of glycerol and phosphoric acid in a vacuum, the mixture is transformed quantitatively into the normal tri-ester. W. G.

Crystalline Forms of Salts of Ethanedisulphonic Acid. K. BLEICHER (*Zeitsch. Kryst. Min.*, 1912, **51**, 502—520).—Detailed crystallographic constants are given for the following salts of ethanedisulphonic acid : Sodium $(2H_2O)$, monoclinic ;

$$a:b.c = 0.7893:1:0.4634;$$

$\beta = 91°34'$. Lithium $(2H_2O)$, monoclinic; $a:b:c = 1.5717:1:2.5939$; $\beta = 111°7'$. Potassium, monoclinic; $a:b:c = 1.2594:1:5816$; $\beta = 126°18'$. Ammonium, monoclinic; $a:b:c = 1.1647:1:0.6959$; $\beta = 120°21'$. Potassium sodium $(2H_2O)$, rhombic;

$$a:b:c = 0.7467:1:0.5563.$$

Disodium ammonium, $Na_4(NH_4)_2(C_2H_4S_2O_6)_3$, monoclinic; $a:b:c = 1.5637:1:0.5906$; $\beta = 101°17'$. Lithium potassium $(1H_2O)$, monoclinic; $a:b:c = 1.2401:1:1.2753$; $\beta = 104°41'$. Lithium ammonium, monoclinic; $a:b:c = 0.7627:1:0.7799$; $\beta = 96°46'$. Barium, rhombic; $a:b:c = 0.7678:1:0.9062$. Barium (H_2O), rhombic; $a:b:c = 0.9374:1:0.4051$. Strontium (H_2O), monoclinic;

$$a:b:c = 0.5347:1:0.0641;$$

$\beta = 101°3'$. Cadmium $(2H_2O)$, triclinic; $a:b:c = 1.7421:1:1.0515$; $a = 90°1'$, $\beta = 101°56'$, $\gamma = 100°54'$. Zinc $(3H_2O)$, triclinic; $a:b:c =$

$0.5718 : 1 : 0.7813$; $a = 94°0'$, $\beta = 110°28'$, $\gamma = 90°30'$. Magnesium ($4H_2O$), triclinic ; $a : b : c = 0.6546 : 1 : 0.4066$; $a = 96°18'$, $\beta = 102°9'$, $\gamma = 94°14'$. Copper ($4H_2O$), triclinic ; $a : b : c = 0.6527 : 1 : 0.4350 :$ $a = 95°15'$, $\beta = 96°39'$, $\gamma = 94°32'$. L. J. S.

Phenomenon of Double Melting for Fats. ANDREAS SMIT, and S. C. BOKHORST (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, 15, 681—683).—According to Guth (A., 1903, i, 225), tristearin melts at 71·5°, but if allowed to solidify in a capillary tube it melts at 55°, solidifies again, and melts a second time at 71·5°. In view of the improbable explanation of these results, the authors have made a further examination of the behaviour of the substance, and find that the above phenomena are due to the existence of two crystalline modifications. Of these, the metastable form appears most readily. If, however, the liquid is kept for some time at a temperature between the two melting points, the stable form crystallises out, although very slowly.

When the metastable form is heated, it melts at 54·5°, and when the temperature is then raised to 63° the stable form is deposited. The stable unary melting point is 70·8°. It is probable that the double melting phenomena, observed for other fats, are to be explained in the same way. H. M. D.

Anomalies in the Consistency and Melting Points of Fats. ADOLF GRÜN (*Ber.*, 1912, 45, 3691—3701).—It has already been observed that glycerides can exist in two modifications (Kast, A., 1906, i, 922 ; Grün and Schacht, A., 1907, i, 462). To this phenomenon is attributable the variation in the m. p. recorded for certain fats with the age or method of preparation of the sample. The present investigation endeavours to extend the present limited knowledge of this phenomenon.

[With A. CUSTODIS].—$a\gamma$-Dilaurin, obtained from $a\gamma$-dichlorhydrin and potassium laurate, is a mixture of two modifications ; the product of higher m. p., 57°, *acetyl* derivative, m. p. 34°, or after one year 32°, is obtained in better yield the lower the reaction temperature (140—150°), whilst the other modification, m. p. 40°, preponderates when the temperature of formation is somewhat higher (170—180°) ; the latter modification very easily remains in a supercooled condition. Both forms, on keeping, finally attain a m. p. 45°, which is also the temperature observed for a mixed m. p. It is probable that the two substances are structurally identical.

When the two forms of $a\gamma$-dilaurin are treated with lauryl chloride at 100°, two modifications of trilaurin are obtained, one m. p. 45°, the other forming soft needles which melt in the hand. The former, obtained from the less fusible dilaurin, is identical with natural trilaurin ; the latter, obtained from the more fusible dilaurin, resembles its parent substance in having in benzene a molecular weight only one-half that expected from the formula ; the less fusible di- and tri-laurins are of normal molecular weight.

$a\gamma$-Dibenzoin, $OBz \cdot CH_2 \cdot CH(OH) \cdot CH_2 \cdot OBz$, by warming with glycerol and sulphuric acid, can be converted into a modification

which remains oily at the ordinary temperature ; the molecular weight of the substance in benzene solution is, however, approximately normal.

$a\beta$-Dibenzoin, obtained from anhydrous potassium benzoate and $a\beta$-dibromohydrin, and al-o in a purer condition by the use of silver benzoate, is also a viscous, uncrystallisable oil.

In an addendum it is remarked that lack of recognition of the above peculiarities of glycerides may lead to considerable errors, as, for example, the reported formation of $a\beta$-dilaurin from $a\gamma$-dichlorohydrin (van Eldik Thieme, A., 1912, i, 333).   D. F. T.

The Synthesis of Fats. DAVID HOLDE (*Ber.*, 1912, 45, 3701—3702. Compare Kremann and Schoulz, A., 1912, ii, 1152).— The author draws attention to the manner in which the results of Kremann and Schoulz (*loc. cit.*) support his views (A., 1903, i, 140) that the stearic and palmitic acids in olive oil must be present in the form of " mixed " glycerides, and not as tripalmitin and tristearin.
                                                           D. F. T.

Diglyceride-phosphoric Acids. ADOLF GRUN and FRITZ KADE (*Ber.*, 1912, 45, 3358—3367).—When phosphoric oxide acts on distearin at temperatures above 100°, or in the absence of moisture, blackening takes place. When the requisite amount of water is added, esters of pyrophosphoric acid or primary orthophosphoric acid esters are obtained. The former decompose into phosphoric acid and the ortho-acid esters, which are transformed in turn into secondary and tertiary esters and finally into the stable form, pentadistearin phosphate. In addition the reaction product contains free phosphoric acid and distearin. The changes are expressed by the scheme :

$$PO(OR)(OH)\cdot O\cdot PO(OH)_2 \longrightarrow PO(OR)(OH)_2 \longrightarrow$$
$$PO(OR)_2(OH) \longrightarrow PO(OR)_3 \longrightarrow P(OR)_5.$$
$a\beta$-*Distearin pyrophosphate*, $C_3H_5(O\cdot CO\cdot C_{17}H_{35})_2\cdot O\cdot P_2H_3O_6$, is a colourless, crystalline, fatty substance, m. p. about 65°; primary $a\beta$-*distearin orthophosphate* forms colourless, somewhat lustrous, matted crystals, m. p. 71°. The *secondary* ester yields soft crystals, m. p. about 67°; it forms a waxy, pale yellow *silver* salt with silver acetate, and a *potassium* salt separating in colourless platelets. The *tertiary* ester is very similar to the other esters, but the solution is neutral.

Pentadistearin phosphate, $P[O\cdot C_3H_5(O\cdot CO\cdot C_{17}H_{35})_2]_5$, forms colourless, brittle crystals, m. p. 70°. All the compounds described are very ill-defined.   E. F. A.

Alleged Synthesis of Lecithins. ADOLF GRÜN and FRITZ KADE (*Ber.*, 1912, 45, 3367—3376).—To effect the synthesis of lecithins it is proposed to allow the components of choline to act in turn on diglyceride-phosphoric acid. Ethylene glycol and phosphoric oxide acting on distearin produce almost quantitatively *distearin ethylene-glycol orthophosphate*,

$$C_3H_5(O\cdot CO\cdot C_{17}H_{35})_2\cdot O\cdot PO(OH)\cdot O\cdot C_2H_4\cdot OH.$$
When ethylene chlorohydrin is used, the reaction takes place in two directions, the glycol ester as well as the β-*chloroethyl* ester,

$$C_3H_5(O\cdot CO\cdot C_{17}H_{35})_2\cdot O\cdot PO(OH)\cdot O\cdot C_2H_4Cl,$$
being formed. This compound reacts with trimethylamine, forming the *trimethylammonium* salt,

$$C_3H_5(O \cdot CO \cdot C_{17}H_{35})_2 \cdot O \cdot PO(O \cdot C_2H_4Cl) \cdot O \cdot NHMe_3,$$
and on more energetic action of excess of trimethylamine this undergoes rearrangement to lecithin hydrochloride,

$$C_3H_5(O \cdot CO \cdot C_{17}H_{35})_2 \cdot O \cdot PO(O \cdot C_2H_4 \cdot NMe_3Cl) \cdot OH.$$
The final product obtained was a mixture of both compounds together with an intermediate product.

The *β-chloroethyl* ester, from *αβ*-distearinphosphoric acid, forms colourless crystals, which sinter at 60°, m. p. 65—66°; the isomeric *αγ*-distearin compound is very similar.

The *ethyleneglycol* ester of *αβ-distearinphosphoric* acid has m. p. 65—70°, and is a typically fatty substance. It reacts faintly acid.

The *trimethylammonium* salt forms tough crystals which sinter at 60°, m. p. 69°.

The synthetic lecithin hydrochloride (*αβ*-distearincholinephosphoric acid ester) product is a soft, waxy compound, which sinters at 60° to a clear, viscid oil, which becomes mobile at 64—65° and opaque at 74°.

E. F. A.

Preparation of Mixed *αβ*-Diglycerides. ADOLF GRUN and B. SCHREYER (*Ber.*, 1912, **45**, 3420—3426).—Glycerol-*α*-monochlorohydrin is converted by the action of myristoyl chloride into the ester, $CH_2Cl \cdot CH(OH) \cdot CH_2 \cdot O \cdot CO \cdot C_{13}H_{27}$, which reacts with stearyl chloride to form myristostearochlorohydrin,

$$CH_2Cl \cdot CH(O \cdot CO \cdot C_{17}H_{35}) \cdot CH_2(O \cdot CO \cdot C_{13}H_{27}).$$

On treatment with silver nitrite the chlorine atom is replaced by hydroxyl and *α*-myristo-*β*-stearin obtained.

α-Myristo-γ-chlorohydrin is a yellow, mobile oil; it is converted by silver nitrite into *α*-monomyristin, m. p. 68°.

β-Myristo-αγ-dichlorohydrin forms colourless, transparent, glass-like crystals, m. p. 20°. The *β-monomyristin* obtained from it gives colourless, lustrous, crystalline plates, m. p. 69°.

α-Myristo-β-stearo-γ-chlorohydrin forms colourless crystals, m. p. 31°.

α-Myristo-β-stearin crystallises in slender platelets, m. p. 58°.

E. F. A.

Alcoholysis and the Composition of Cocoanut Oil. GEORGE D. ELSDON (*Analyst*, 1913, **38**, 8—11).—Cocoanut oil when boiled in a reflux apparatus with absolute methyl alcohol containing 2% of hydrogen chloride for about twenty hours deposits on cooling a large quantity of methyl esters; the remainder may be obtained by diluting the alcoholic solution with water and agitating with ether.

When the mixture of the esters is submitted to distillation at 14 mm. pressure, seven fractions may be isolated (b. p. 63—76°, 76—100°, 100—128°, 128—153°, 153—182°, 182—204°, 204—216°).

From the results obtained on weighing, refractionating, and further identification of the fractions, the author considers that the composition of the fatty acids and of cocoanut oil may be represented approximately

by hexoic acid 2%, octoic acid 9%, decoic acid 10%, lauric acid 45%, myristic acid 20%, palmitic acid 7%, stearic acid 5%, and oleic acid 2%.

L. DE K.

Preparation of Ethyl Acrylate. FREDERICK G. TROBRIDGE (*Proc. Univ. Durham, Phil. Soc.*, 1912, **4**, 223—224).—Ethyl acrylate is obtained in 80% yield by the action of the zinc–copper couple on ethyl $\alpha\beta$-dibromopropionate in ethereal solution.   F. B.

Action of Zinc on a Mixture of Pinacolin and Ethyl α-Bromopropionate. NICOLAI N. BUNGE (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1776—1788).—This incomplete investigation is published owing to the appearance of Umnova's paper (this vol., i, 7), and is a continuation of work begun by Lazarkevitsch and proceeded with by Reformatski and Agafonov.

The products of the action of zinc on a mixture of pinacolin (1 mol.) and ethyl bromopropionate (1 mol.) vary with the conditions of the reaction. If the latter takes place at the ordinary temperature and the viscous mass obtained after three or four days is decomposed with water, a yield of 30% of ethyl β-hydroxy-$\alpha\beta\gamma\gamma$-tetramethylvalerate is obtained. At 50—70°, however, this ester is accompanied by (1) a lactone, $C_9H_{16}O_2$, which may also be obtained by boiling either the ester or the corresponding acid for some hours with 20% sulphuric acid solution ; (2) ethyl propionylpropionate, which yields diethyl ketone on hydrolysis.

β-*Hydroxy-$\alpha\beta\gamma\gamma$-tetramethylvaleric acid,*

$$CMe_3 \cdot CMe(OH) \cdot CHMe \cdot CO_2H,$$
forms large, colourless crystals (? rhombohedra), m. p. 109·5—110·5°, and has the normal molecular weight in freezing acetic acid. Its *ethyl* ester, $C_{11}H_{22}O_3$, is a colourless, viscous liquid, b. p. 117°/20 mm., D_4^{20} 0·96034, n_D^{20} 1·44039, and exhibits normal cryoscopic behaviour in benzene. The *potassium, barium, calcium* ($+ H_2O$), and *silver* salts were analysed.
The *lactone,* $CMe_3 \cdot CH < \begin{smallmatrix} CHMe \cdot CO \\ CH_2 — O \end{smallmatrix}$ or $CMe_2 < \begin{smallmatrix} CHMe \cdot CO \\ CMe_2 — O \end{smallmatrix}$, forms large crystals, m. p. 65—66°, and exhibits the normal molecular weight in freezing acetic acid ; when boiled with water it yields a neutral solution and does not combine with it.   T. H. P.

Uranium Salts. ARRIGO MAZZUCCHELLI and OLGA GRECO D'ALCEO (*Atti R. Accad. Lincei*, 1912, [v], **21**, ii, 620—626).—The paper deals with complex uranium salts. Additive products are practically not formed in the following cases : mercuric cyanate, carbamide or thiocarbamide with uranyl nitrate ; carbamide or hexamethylenediamine with uranyl oxalate ; hexamethylenediamine, aniline or pyridine with the complex sodium uranyl pyrophosphate, malonate or succinate. Attempts to prepare complex salts from aminoacetic, aspartic, aminobenzoic and sulphanilic acids were unsuccessful. The *aspartate,*

$$UO_2(C_4H_5O_4N)_2,3H_2O,$$

was prepared, but it is not a complex derivative. The *aminobenzoate,* $UO_2(C_7H_6O_2N)_2,4H_2O$, was obtained, and also the basic *sulphanilate,* $UO_2 \cdot C_6H_7O_3NS,H_2O$.

The uranous salts also appear to have little tendency to form aminic

complexes. Diurano-oxalic acid gives ordinary *salts* with *pyridine* $[2U(C_2O_4)_2 \cdot C_2O_4(C_5H_5N)_2]$ and with *aniline* $[2U(C_2O_4)_2 \cdot C_2O_4(C_6H_7N)_2]$. Indications were obtained of the formation of a complex salt in the case of uranous aminoacetate. The basic *succinate*, $UO \cdot C_4H_4O_4, 2H_2O$, was prepared, and also the analogous *malonate*, $UO \cdot C_3H_2O_4, 6H_2O$. When a solution of sodium uranylmalonate with an excess of malonic acid is electrolytically reduced, the anodic liquid being an acid solution of sodium malonate separated from it by a parchment, dark green, dichroic crystals of the complex *salt*, $U(C_3H_2O_4)_2Na_2, 2H_2O$, are obtained on subsequent concentration of the cathodic liquid in a vacuum. A basic *uranous phthalate*, $UO:C_8H_4O_4, 3H_2O$, and *uranous trichloroacetate*, $UO \cdot C_2O_2Cl_3)_2, 3H_2O$, were also prepared.

R. V. S.

Molecular Rearrangements in the Camphor Series. XI. Derivatives of *iso*Camphoric Acid : *iso*Aminocamphonanic Acid and Its Decomposition Products. WILLIAM A NOYES and LEONIDAS R. LITTLETON (*J. Amer. Chem. Soc.*, 1913, **35**, 75—81). —It has been shown in earlier papers (A., 1895, i, 295 ; 1909, i, 133) that aminocamphonanic acid (aminolauronic acid) is decomposed by nitrous acid with formation of lauronolic acid, laurolene, and *iso*-campholactone. The present work was undertaken with the object of preparing *iso*aminocamphonanic acid and studying its behaviour with nitrous acid.

sec.-Methyl *iso*camphorate (α-methyl *iso*camphorate),
$$CO_2H \cdot C_8H_{14} \cdot CO_2Me,$$
has m. p. 89·5—90°, and $[\alpha]_D - 58·4°$ in 10% alcoholic solution (compare Noyes and Knight, A., 1911, i, 111). The tert.-*methyl* ester, prepared by boiling a solution of the dimethyl ester in methyl alcohol with sodium hydroxide, was obtained as a very viscous oil ; it has $[\alpha]_D - 53·1°$ in 10% alcohol solution. The terms "secondary" and "tertiary" are used here to indicate the carboxyl containing the methyl group.
Methyl sec.-*isocamphoramate*, $CO_2Me \cdot C_8H_{14} \cdot CO \cdot NH_2$, m p. 126—127°, prepared from the *sec.*-methyl ester by converting it into the chloride and treating the latter with ammonia, crystallises in rectangular plates, and has $[\alpha]_D - 54·1°$ in 10% solution in methyl alcohol. When this ester is warmed with sodium hypobromite solution it yields *methyl* iso*aminocamphonanate*, b. p. 239° (corr.), m. p. 230° (decomp.), which forms white crystals ; the *hydrochloride*,
$$CO_2Me \cdot C_8H_{14} \cdot NH_2, HCl, H_2O,$$
has $[\alpha]_D - 32·03°$ in 10% solution in water, and $- 42·03°$ in 10% solution in alcohol. If this hydrochloride is warmed with solution of sodium hydroxide and subsequently acidified with hydrochloric acid, the *hydrochlo ide* of isoaminocamphonanic acid,
$$\begin{array}{c} CH_2-CH_2 \\ NH_2 \cdot CH \cdot CMe_2 \end{array}\!\!\!>CMe \cdot CO_2H, HCl,$$
m. p. 320° (corr.), is obtained, which is decomposed by nitrous acid with formation of *cis*-camphonolactone, together with small quantities of an unsaturated *acid*, b. p. 150°/60 mm. (decomp.), and a saturated acid which decomposes at 160°.
E. G.

New Methods of Preparation of Camphonenic (γ-Lauronolic) Acid and the Relation of the Latter to Laurolenic (Lauronolic) Acid. JULIUS BREDT [and, in part, PAUL LEVY and S. LINK] (*J. pr. Chem.*, 1913, [ii], 87, 1—11).—The first part of this paper is mainly a summary of the authors' views on the constitution and relationships of the lauronolic acids and allied compounds, together with suggestions concerning their nomenclature (compare A., 1911, i, 417).

When submitted to slow distillation, dehydrocamphoric acid (A., 1902, i, 374) loses carbon dioxide, yielding γ-lauronolic (camphonenic) acid (I). It is accompanied by *iso*dehydrocamphoric anhydride, from which it may be separated by distillation in steam. When purified by the calcium salt, $C_{18}H_{26}O_4Ca,H_2O$, and repeatedly crystallised from dilute acetic acid it is obtained in feather-like crystals, m. p. 155—156° (compare Noyes, A., 1912, i, 159).

Dehydrocamphoric acid combines with hydrobromic acid, yielding a mixture of two stereoisomeric *hydrobromides* (II), of which the *cis*-form has m. p. 168—170°, and is reduced by zinc and acetic acid to *cis*-camphoric acid, whilst the *cis-trans*-modification has m. p. 232°, and on reduction yields *cis-trans*-camphoric acid :

$$CH{=}C{\cdot}CO_2H \qquad CHBr{\cdot}CH{\cdot}CO_2H \qquad CH(OH){\cdot}CH$$
$$\overset{|}{C}Me_2 \qquad\qquad \overset{|}{C}Me_2 \qquad\qquad\quad \overset{|}{C}Me_2$$
$$\overset{|}{C}H_2{\cdot}CMe{\cdot}CO_2H \quad \overset{|}{C}H_2{-}\overset{|}{C}Me{\cdot}CO_2H \quad \overset{|}{C}H_2{-}\overset{|}{-}CMe{\cdot}CO_2H$$
$$\text{(I.)} \qquad\qquad\qquad \text{(II.)} \qquad\qquad\qquad \text{(III.)}$$
When boiled in aqueous solution the sodium salt of the *cis-trans*-hydrobromide yields as main product a *hydroxy-acid* (III), which is accompanied by γ-lauronolic acid (10%).

Oxidation of γ-lauronolic acid with nitric acid, or of its calcium salt with potassium permanganate, gives rise to camphoronic acid.   F. B.

A New Method of Preparation of Laurolenic (Lauronolic) Acid and the Decomposition of Camphanic Acid in an Electric Reflux Heater under Diminished Pressure. JULIUS BREDT and AUGUST AMANN (*J. pr. Chem.*, 1913, [ii], 87, 12—26).—Lauronolic acid, which the authors now terms laurolenic acid, is obtained by boiling γ-camphonanic acid (A., 1912, i, 113) for a short time with aqueous sodium carbonate. It is accompanied by camphonololactone, and has also been prepared (1) by distillation of camphanic acid under diminished pressure in a specially constructed, electrically heated apparatus, a sketch of which is given, and (2) by heating chlorocamphoric anhydride (A., 1912, i, 411) with aqueous sodium carbonate. The m. p. of the acid varies from 5·5—7° to 8·5—10° according to its method of preparation, and $[a]_D$ from 181·3° to 195·2°.

The calcium salt separates from its aqueous solution at the ordinary temperature with $2H_2O$, and not $3H_2O$, as stated by Noyes and Burke (A., 1912, i, 159).   F. B.

Methods for the Preparation of Neutral Solutions of Ammonium Citrate. JAMES M. BELL and CHARLES F. COWELL (*J. Amer. Chem. Soc.*, 1913, 35, 49—54).—The methods at present

employed for the preparation of neutral solutions of ammonium citrate are not satisfactory and two new methods have therefore been devised. In one of these methods, the excess of ammonia is estimated by extracting the solution with chloroform, and titrating the chloroform with 0·1N-hydrochloric acid in presence of methyl-red as indicator. In the other method, the rise of temperature due to the heat of neutralisation is observed as the citric acid solution is titrated with ammonia, the end-point being at the break in the heating curve. Both these methods are considered to be simpler than that involving the determination of the conductivity of solutions at constant temperature.

E. G.

Thio-γ-valerolactone. KARL FRIES and H. MENGEL (*Ber.*, 1912, 45, 3408—3411).—On heating valerolactone with phosphorus pentasulphide, *thio-γ-valerolactone*, $CHMe{<}^{CH_2 \cdot CH_2}_{S\ ---\ CO}$, is obtained as a colourless oil of pleasant aromatic odour, b. p. 94—95°/20 mm. It is readily hydrolysed by alkali hydroxides to γ-mercaptovaleric acid, which is reconverted into the thiolactone on treatment with mineral acids.

A further product of the action of the pentasulphide is *dithio-γ-valerolactone*, $CHMe{<}^{CH_2 \cdot CH_2}_{S\ ---\ CS}$, an orange-coloured, viscid oil of unpleasant odour. Condensing agents such as sodium methoxide convert it very readily into *trithio-di-γ-valerolactone*,

$$CHMe{<}^{CH_2 \cdot CH_2}_{S\ ---\ C}\ \ {}^{CS \cdot S}_{C \cdot CH_2}{>}CHMe,$$
which crystallises in bunches of large, red prisms, m. p. 77°.

E. F. A.

Maleindialdehyde. ALFRED WOHL and BRUNO MYLO (*Ber.*, 1912, 45, 1746—1756).—Maleindialdehyde diethylacetal, an intermediate product in the preparation of tartardialdehyde (A., 1912, i, 162), has been hydrolysed by means of dilute sulphuric acid, and the maleindialdehyde has been characterised. The most striking property of this compound is its yellow colour, which is more intense than that of diacetyl and may be accounted for by the grouping together of conjugated double bonds and the conveying of the influence of one carbonyl group to the other by an ethylenic linking. Oxidation by silver carbonate gives maleic and also fumaric acids, and since the original acetal yields a tartardialdehyde acetal of the type of mesotartaric acid (*ibid.*), it is suggested that this is the real maleindialdehyde, whereas that obtained by Marquis from nitrosuccinaldehyde monoacetin (A., 1905, i, 224) is fumardialdehyde, especially as the nitrous acid which is formed at the same time has a great tendency to convert maleic into fumaric acid.

For the preparation of *maleinlialdehyde*, $CHO \cdot CH{:}CH \cdot CHO$, 35 grams of the acetal are shaken with 150 c.c. of $N/10$-sulphuric acid and the faintly yellow, pungent smelling solution is exactly neutralised with barium hydroxide. After removing the barium sulphate by centrifugation, the solution is evaporated at 40° in a vacuum with a

fractionating column which, however, does not prevent the loss of some aldehyde, since it is volatile in steam, and the residue is extracted with chloroform and dried. The extract is evaporated in the same way and the syrupy residue is maintained at 105—115°/9 mm., when the polymeric substances slowly decompose and the aldehyde distils over. The distillate is collected in a Claisen flask in a freezing mixture and redistilled from a bath already heated to 75°, when the mobile, yellow, pungent-smelling aldehyde boils at 56—59°/9·5 mm. It dissolves in water and organic solvents, and probably forms hydrates and alcoholates, since yellow aqueous or alcoholic solutions soon become colourless. It is only slowly affected by oxygen or bromine water, but it immediately reduces permanganate or ammoniacal silver oxide. At the ordinary temperature it very quickly changes to a syrup with less intense colour and odour, and it is then only slightly soluble in ether, benzene or warm water. From the aqueous solution an amorphous solid separates out ; probably a syrupy and a solid polymeride exist.

Derivatives of the dialdehyde have been prepared by hydrolysing the acetal, exactly neutralising with sodium carbonate, and precipitating with the free base in the cold. The *diphenylhydrazone*, NHPh·N:CH·CH:CH·CH:N·NHPh, forms unstable, yellow, quadratic leaflets from hot alcohol, m. p. 198—199°; Marquis's dihydrazone melts at 236—237° (*ibid.*). It gives a reddish-violet compound on oxidation, which is similar to, but not identical with, Marquis's "tetrazone" ; they are probably not tetrazones at all. The *dioxime*, $C_4H_6O_2N_2$, forms pure white needles from hot methyl alcohol which decompose with violence at 150—155°; Marquis's compound decomposes at 220° (*ibid.*). The *disemicarbazone*, $C_6H_{10}O_2N_6$, is only very slightly soluble, and crystallises best from a large volume of boiling water in slender needles, m. p. 246—247° (corr.).   J. C. W.

The Isomeric Changes of Dextrose Produced by Alkalis. Theory of Catalytic Action. LEONOR MICHAELIS and PETER RONA (*Biochem. Zeitsch.*, 1912, **47**, 447—461).—The changes in dextrose (measured chiefly polarimetrically) produced by alkalis (in presence of phosphates, etc., added to keep the hydrogen-ion concentration constant during the experiment) is directly proportional to the hydroxyl-ion concentration. The acid nature of dextrose was demonstrated, and its dissociation constant was found to be $5 \cdot 10^{-13}$. This was measured by ascertaining the changes in the hydroxyl-ion concentration of sodium hydroxide solutions (measured electrometrically) produced by the addition of dextrose. From these facts, the hypothesis is put forward, that the "catalytic" action of the hydroxyl ions increases the number of sugar ions, according to theory of mass action, and it is the latter which spontaneously undergo isomeric change.   S. B. S.

Conversion of *d*-Glucose [Dextrose] into a Methylpentose. EMIL FISCHER and KARL ZACH (*Ber.*, 1912, **45**, 3761—3773).— Triacetylmethylglucoside bromohydrin (Fischer and Armstrong, A., 1902, i, 263), $CH_2Br·CH(OAc)·OH·CH(OAc)·CH(OAc)·CH(OMe)$
is converted on reduction with acetic acid and zinc dust into a tri-acetyl derivative which on alkaline hydrolysis yields *β-methyl*-d-*iso*-*rhamnoside*, $CH_3 \cdot CH(OH) \cdot CH \cdot CH(OH) \cdot CH(OH) \cdot CH \cdot OMe$. This is

$$CH_3 \cdot \overset{H}{\underset{\overset{|}{OH}}{\overset{|}{C}}} - \overset{H}{\underset{'}{\overset{|}{C}}} - \overset{OH}{\underset{\overset{|}{H}}{\overset{|}{C}}} - \overset{H}{\underset{\overset{|}{OH}}{\overset{|}{C}}} - CH \cdot OH$$

hydrolyed by acids to *d-iso*rhamnose (annexed formula), which is identical with the *iso*rhodeose described by Votoček (A., 1911, i, 354), and obtained by him from purgic acid. Since no asymmetric carbon atom is concerned in the series of reactions, no Walden rearrangement is possible, and the methylpentose has the same configuration as *d*-glucose.

Accordingly the annexed formula of *l*-rhamnose (methyl-*l*-mannose), which was hitherto uncertain, is established.

$$CH_3 \cdot \overset{OH}{\underset{\overset{|}{H}}{\overset{|}{C}}} - \overset{H}{\underset{\overset{|}{H}}{\overset{|}{C}}} - \overset{H}{\underset{\overset{|}{OH}}{\overset{|}{C}}} - \overset{}{\underset{\overset{|}{OH}}{\overset{|}{C}}} - CH \cdot OH$$

β-Methyl-*d-iso*rhamnoside, like *β*-methylglucoside, is hydrolysed by emulsin, whereas *β*-methylxyloside is not attacked. Renewed emphasis is laid on this remarkable difference in view of the similarity in structure of ·the three glucosides.

Triacetyl-methyl-d-*iso*rhamnoside crystallises in well-formed, colour-less needles, m. p. 100° (corr.), $[a]_D^{20} - 20 \cdot 22°$.

β-Methyl-d-*iso*rhamnoside forms slender, colourless needles, m. p. 133° (corr.), $[a]_D^{20} - 55 \cdot 3°$, which taste bitter.

*d-iso*Rhamnose separates in hard, colourless crystals in a variety of forms, m. p. 139—140° (corr.). The rotation changes from $[a]_D^{20} + 73 \cdot 3°$ to $+ 29 \cdot 7°$ in aqueous solution.

*d-iso*Rhamnosephenylosazone crystallises in yellow needles, m. p. 185° (corr.), to a dark red liquid (compare Votoček, *loc. cit.*), $[a]_D^{20} - 95°$ in white light; it is the optical antipode of *l*-rhamnosephenyl-osazone.

*d-iso*Rhamnonolactone has m. p. 151—152° (corr.), $[a]_D^{20}$ changing from $+ 66 \cdot 88°$ to $+ 5 \cdot 35°$.   E. F. A.

Properties of Phytin. M. A. EGOROV (*Bied. Zentr.*, 1912, 42, 66—67 ; from *J. Exper. Landw.*, 1912, 12, 361).—The phosphoric acid of phytin, which is precipitated by acid molybdate solution, is not pre-cipitated under ordinary conditions in ammonium citrate solution by magnesia mixture.

When phytin is boiled with water for fourteen to sixteen hours it is completely decomposed with production of inositol and inorganic phosphoric acid compounds. The yield of phosphoric acid is about 100%.   N. H. J. M.

Formation of Humus and Combustible Minerals without the Intervention of Atmospheric Oxygen, Micro-organisms, High Temperatures, or Great Pressure. LOUIS C. MAILLARD (*Compt. rend.*, 1912, 155, 1554—1556).—A theoretical discussion of work previously described (compare A., 1912, i, 13, 169). The author has now shown that oxidation does not intervene in any way in

the generation of carbon dioxide and the production of humic substances by the interaction of sugars and amino-acids. He has further obtained a jet black substance, rich in carbon and containing nitrogen, which exhibits a remarkable resistance to reagents, and he suggests that this reaction should be taken into account in framing theories as to the formation of combustible minerals.   W. G.

Some Unstable Nitrites Fixed by means of Organic Bases. III. GINO SCAGLIARINI (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 640—643).—The author describes stable compounds of the nitrites of mercury, zinc, and cadmium with hexamethylenetetramine. The substances were prepared by adding sodium nitrite to a solution of a salt of the metal in the presence of hexamethylenetetramine. The *compound*, $2Hg(NO_2)_2,8H_2O,3C_6H_{12}N_4$, forms white crystals with a greenish lustre. The *compound*, $Zn(NO_2)_2,2H_2O,C_6H_{12}N_4$, forms colourless prismatic crystals, as does also the *compound*,

$$Cd(NO_2)_2,2H_2O,C_6H_{12}N_4.$$ R. V. S.

Alloxan Anhydride and Its Methyl Derivatives. HEINRICH BILTZ (*Ber.*, 1912, 45, 3659—3675).—By heating under reduced pressure it is found possible completely to dehydrate alloxan and its methyl and dimethyl derivatives ; the anhydrous substances have an intense yellow colour and can be sublimed unchanged in a vacuum.

Alloxan anhydride, $C_4H_2O_4N_2$, obtained by heating the monohydrate for an hour at 210—220° in a vacuum produced by a mercury pump, forms yellow, rhombic crystals ($a:b:c=0.9974:1:1.6841$), m. p. 256° (decomp.). A partial dehydration of the monohydrate is also effected by recrystallising from acetic acid.

Methylalloxan anhydride, obtained from the monohydrate by similar treatment to the previous but at 160°, separates from acetic acid in leafy crystals (rhombic system, $a:b:c=0.6766:1:?$), m. p. 154—156° (decomp.).

Dimethylalloxan anhydride (compare Holleman, A., 1897, i, 599) could be obtained from the monohydrate by heating in a water-pump vacuum at 210—220°; it crystallises from benzyl cyanide in short, yellow columns (rhombic system, $a:b:c=0.6847:1:?$).

[With E. TOPP.]—The above anhydrous compounds separated from alcohols containing a little hydrogen chloride in the form of alcoholates which are analogous to the phenolates described earlier (Boehringer & Söhne, D.R.P. 1898, 107720; 1899, 113722). *Alloxan ethyl alcoholate*, $CO\!<\!{{NH-CO}\atop{NH-CO}}\!>\!C(OH)\cdot OEt$, prisms; *alloxan methyl alcoholate*, prisms; *alloxan benzyl alcoholate*, prisms.

Methylalloxan ethyl alcoholate, tablets.

*Dimethylalloxan ethyl alcoholate*, tetragonal prisms, m. p. 95°; *dimethylalloxan methyl alcoholate*, m. p. circa 90°, hexagonal tablets; *dimethylalloxan benzyl alcoholate*, crystals, m. p. 185—188°.

All these alcoholates when heated eliminate the molecule of alcohol, giving a residue which has approximately the m. p. of the pure anhydride.

The following compounds were prepared by crystallisation from a

solution of the anhydride and a phenol with hydrogen chloride in acetic acid ; *alloxan phenolate*, decomposing at 240—245°; alloxan *p*-cresolate decomposing at 228—230° (compare Boehringer & Söhne, *loc. c.t.*); *dimethylalloxan* p-*cresolate*, hexagonal prisms, m. p. 105°.

[With J. KARTTE.]—An aqueous solution of dimethylalloxan dihydrate when saturated with sulphur dioxide and evaporated in a vacuum desiccator deposits *dimethylalloxan sulphite*,

$$CO<^{NMe\cdot CO}_{NMe\cdot CO}>C(OH)\cdot SO_3\cdot C(OH)<^{CO\cdot NMe}_{CO\cdot NMe}>CO,$$
colourless prisms, which decompose at 75°. *Methylalloxan sulphite*, obtained in an analogous manner, crystallises in prisms with $4H_2O$. *Alloxan sulphite* forms rhombic leaflets, decomposing near 184°.

Alloxan anhydride condenses in alcoholic acetic acid solution with dimethylcarbamide producing 7 : 9-dimethyluric acid glycol (compare Biltz and Krebs, A., 1910, i, 526), but the product from dimethylalloxan anhydride and dimethylcarbamide was allocaffeine (compare Biltz and Krebs, *loc. cit.*, i, 521).

Working details are given of the methods found most suitable for the preparation of di- and tetra-methylalloxantin and their conversion into methyl- and dimethyl-alloxans.   D. F. T.

The System Ammonium Thiocyanate–Thiocarbamide–Water. ANDREAS SMITS and A. KETTNER (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, 15, 683—686).—The investigation of the melting-point diagram of the pseudo-binary system ammonium thiocyanate–thiocarbamide has given results which indicate the existence of a compound $NH_4CNS,4CS(NH_2)_2$, whereas Atkins and Werner (T., 1912, 101, 1167) are of the opinion that the compound has the composition $NH_4CNS,3CS(NH_2)_2$. The evidence for the former is supported by the results of the determination of the solubility isotherms at 25° and the examination of the co-existing solid phases by the residue method. The solubility curves afford a simple explanation of the method of preparation of thiocarbamide from ammonium thiocyanate recommended by Reynolds and Werner (T., 1903, 83, 1), which up to the present has not been satisfactorily accounted for.   H. M. D.

Selective Catalysis of Dehydrogenation. NICOLAI D. ZELINSKI (*Ber.*, 1912, 45, 3678—3682).—The catalytic dehydrogenation of *cyclo*hexane compounds by palladium or platinum at 300° and the inactivity of these metals towards *cyclo*pentane compounds under the same conditions can be applied to the separation of *cyclo*hexane and *cyclo*pentane hydrocarbons.

[With (Frl.) A. HERZENSTEIN.]—After a mixture of equal volumes of methyl*cyclo*pentane and *cyclo*hexane has been thrice submitted to the action of platinum black at 300°, no further liberation of hydrogen occurs, and the hydrogen collected amounts to more than 90% of the theoretical. After removal of the benzene from the resultant hydrocarbon mixture by treatment at the ordinary temperature with sulphuric acid (two volumes of acid, D 1·84, mixed with one volume of fuming acid containing 7% of anhydride), the residual liquid was pure methyl*cyclo*pentane.

*cyclo*Heptane resembles *cyclo*pentane (Zelinski, A., 1911, i, 958) in resisting the above catalytic dehydrogenation.

A specimen of naphtha, b. p. 102—104°, D^{18} 0·7647, n^{18} 1·4215, from Baku petroleum, by the above treatment gave a liquid which could be separated by distillation into two fractions. The less volatile fraction, b. p. 105—107°, contained much toluene, whilst the other fraction, b. p. 104—105°, after one more treatment with platinum black followed by the removal of any aromatic hydrocarbons by means of the special sulphuric acid mentioned above, gave a hydrocarbon, C_7H_{14}, b. p. 101—102·5°/747 mm., D_4^{20} 0·7488, n^{20} 1·4101, which is probably a *cyclo*pentane or *cyclo*butane derivative.

[With W. DOBROCHOTOV.]—Another specimen of naphtha, b. p. 100—100·5°, D^{18} 0·766, $n^{20\cdot5}$ 1·4210, when submitted to the action of platinum black at 300°, liberated much hydrogen, and after the removal of toluene and redistillation had b. p. 100—101°, D_4^{18} 0·7490, n^{18} 1·4142. The original hydrocarbon, a "heptanaphthene," which had been previously treated with a mixture of nitric and sulphuric acids, had therefore yielded a *cyclo*paraffin product very similar to that obtained from the above naphtha fraction (b. p. 102—104°), which had not been first treated with nitric and sulphuric acids.   D. F. T.

Formation of Dimethylstyrene [β-Phenyl-Δ^β-butylene] from Phenyldimethylethyl Alcohol [β-Phenyl*iso*butyl Alcohol]. ALBIN HALLER and ÉDOUARD BAUER (*Compt. rend.*, 1912, 155, 1581—1585).—By the action of sodamide on phenylacetonitrile (1 mol.) in ethereal solution followed by the addition of methyl iodide (1 mol.), a liquid, b. p. 115—120°/19—20 mm., is obtained, which on further treatment with sodamide and methyl iodide gives α-phenyl*iso*butyronitrile (compare Wallach, A., 1900, i, 229). This substance on hydrolysis with 85% sulphuric acid on a water-bath furnishes the corresponding amide, which by reduction with sodium in absolute alcohol yields *β-phenyliso*butyl alcohol, $CPhMe_2·CH_2·OH$, b. p. 122—123°/20 mm., which gives a *phenylurethane*, white needles, m. p. 59—60°. During the reduction there is produced at the same time some β-phenyl*iso*butylamine, b. p. 115—116°/20 mm. (compare Wallach, *loc. cit.*), which forms a *platinichloride*, insoluble in water.

By acting on β-phenyl*iso*butyl alcohol with thionyl chloride in slight excess at 0°, a liquid is obtained separable into two fractions, of which one is β-phenyl·Δ^β-butylene, $CPhMe{:}CHMe$ (compare Klages, A., 1902, i, 666; 1903, i, 19), and the other a *chloride*, $C_{10}H_{13}Cl$, b. p. 104—105°/20 mm., the constitution of which has not yet been established. With silver acetate, it gives an *acetate*, which on saponification gives an *alcohol*, b. p., 115—117°/15 mm., isomeric with the alcohol from which the chloride was derived.   W. G.

2 : 4 : 6-Tribromo-1-iodo-3-nitrobenzene. C. LORING JACKSON and WEBSTER N. JONES (*Amer. Chem. J.*, 1913, 49, 46—55).—2 : 4 : 6-Tribromo-3-nitroaniline (Körner, A., 1876, i, 210) has m. p. 101·5°. Remmers (A., 1874, 696) assigned the m. p. 214—215° to this compound, but it is now shown that his substance was probably 2 : 4 : 6-tribromo-3-nitroacetanilide.   2 : 4 : 6 - Tribromo - 3 - nitrodiacetanilide

(Remmers, *loc. cit.*) has m. p. 168—169°, and seems to be identical with the substance supposed by Wheeler (A., 1896, i, 157) to be the monoacetanilide. 2 : 4 : 6-*Tribromo-3-nitroacetanilide*, m. p. 208—209°, forms white, rhombic crystals.

2 : 4 : 6-*Tribromo-1-iodo-3-nitrobenzene*, $C_6HBr_3I \cdot NO_2$, m.p. 144—145°, obtained by the action of potassium iodide on the diazotisation product of 2 : 4 : 6-tribromo-3-nitroaniline, crystallises in white, rectangular plates. When this substance is treated with a solution of sodium ethoxide, it is converted into a *dibromoiodonitrophenetole*,

$$NO_2 \cdot C_6HBr_2I \cdot OEt,$$
m. p. 121°, which forms long, white, rectangular prisms; other compounds are produced in this reaction, one of which has m. p. 149°.

E. G.

The Nitration of the Chlorotoluenes. ARNOLD F. HOLLEMAN and J. P. WIBAUT (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, 15, 594—599).—The position assumed by a third substituent in a benzene ring depends on the relative velocities of substitution caused by the two substituents already present. The hydroxyl, amino-, halogen and methyl groups which cause ortho-para substitution are placed in the order of decreasing velocity.

In order to obtain further knowledge of the relative substitution velocity caused by different groups, the author has re-investigated the nitration products of *o*-chlorotoluene (Goldschmidt and Hönig, A., 1886, 1022). All four possible chloronitrotoluenes, 2 : 3, 2 : 4, 2 : 5, 2 : 6, were found to be present in the product, although the 2 : 4-isomeride proved difficult of detection. For the estimation of the relative amounts of the isomerides in the nitration product, Valeton's modification of the m.-p. method was used, and indicated in a product obtained at 0° from 10 grams of chlorotoluene and 40 grams of nitric acid (D 1·52), 19·2, 17·0, 43·3, and 20·5% respectively, in the above order.

In extending a similar investigation to the nitration of *m*-chlorotoluene, 3 : 6-, 3 : 5-, 3 : 4-, and 3 : 2-chloronitrotoluenes were prepared in a high state of purity, and had m. p. 24·9°, 58·4°, 24·2°, and 23·4° respectively. Analysis of the reaction product indicated no appreciable quantity of the 3 : 5-isomeride, and 58·9, 32·3, and 8·8% of the remaining three.

By a calculation involving the composition of the nitration products of toluene, chlorobenzene and *p*-chlorotoluene, it is deduced that chlorine causes a velocity of substitution 1·491 times as great as that caused by the methyl radicle. The knowledge of this number allows the calculation of the proportion in which the various isomeric products should be formed in the nitration of *o*- and *m*-chlorotoluenes, and the theoretical proportions exhibit a gratifying concordance with the experimental. D. F. T.

αα Dihalogenoarylsulphonylacetonitriles, $R \cdot SO_2 \cdot CX_2 \cdot CN$, and a Peculiar Reduction of these Halogen Compounds. JULIUS TRÖGER and W. KROSEBERG (*J. pr. Chem.*, 1913, [ii], 87, 67—84. Compare A., 1905, i, 336, 870; 1908, i, 633, 798).—It has been shown previously that αα-dibromoarylsulphonylacetonitriles may be

obtained readily by the action of bromine on the sodium salts of arylsulphonyl-α-oximinoacetonitriles, $SO_2R \cdot C(:NOH) \cdot CN$, in aqueous solution. Attempts to prepare the corresponding dichloro- and di-iodo-compounds in a similar manner were unsuccessful. The dichloro-compounds may, however, be obtained by the addition of bleaching powder to a glacial acetic acid solution of the corresponding arylsulphonylacetonitriles, $SO_2R \cdot CH_2 \cdot CN$.

The following compounds were prepared in this manner: *aa-dichlorobenzenesulphonylacetonitrile*, $SO_2Ph \cdot CCl_2 \cdot CN$, lustrous prisms, m. p. 57°; *aa-p-trichlorobenzenesulphonylacetonitrile*, white needles, m. p. 96—97°; *aa-dichloro-p-bromobenzenesulphonylacetonitrile*, stout needles, m. p. 105—106°; *aa-dichloro-p-iodobenzenesulphonylacetonitrile*, flat prisms, m. p. 111—112°; *aa-dichloro-p-toluenesulphonylacetonitrile*, broad, lustrous needles, m. p. 92°; *aa-dichloro-p-methoxybenzenesulphonylacetonitrile*, m. p. 121°; *aa-dichloro-p-ethoxybenzenesulphonylacetonitrile*, m. p. 95°; *aa-dichloro-ψ-cumenesulphonylacetonitrile*, m. p. 103—104°, and *aa-dichloro-a-naphthalenesulphonylacetonitrile*, m. p. 118°.

The benzenesulphonyl derivative may also be prepared by directly chlorinating benzenesulphonylacetonitrile in glacial acetic acid solution. When dissolved in aqueous sodium hydroxide and the solution treated with a large excess of sodium hypochlorite, benzenesulphonylacetonitrile yields phenyl dichloromethyl sulphone, $CHCl_2 \cdot SO_2Ph$.

aa-Dibromo-p-toluenesulphonylacetonitrile, prepared from *p*-toluenesulphonylacetonitrile and bromine in glacial acetic acid solution, crystallises in long, white prisms, m. p. 121°; *aa-dibromo-o-methoxybenzenesulphonylacetonitrile* forms small prisms, m. p. 123°; *aa-dibromo-p-ethoxybenzenesulphonylacetonitrile*, stout, white needles, m. p. 118°; *aa-dibromo-ψ-cumenesulphonylacetonitrile* crystallises in prisms, m. p. 123°; *aa-dibromo-a-naphthalenesulphonylacetonitrile*, in pale yellow needles, m. p. 146°.

Attempts have been made to prepare compounds of the type $SO_2R \cdot CO \cdot CN$: (1) by hydrolysing the α-oximinoarylsulphonylacetonitriles with dilute acids; (2) by the action of silver oxide on the above dihalogen compounds, and (3) by oxidising the arylsulphonylacetonitriles with potassium permanganate, but so far these attempts have not met with success.

When heated with sodium benzenesulphinate in alcoholic solution, *aa*-dihalogenoarylsulphonylacetonitriles undergo a remarkable reduction to arylsulphonylacetonitriles, thus: $SO_2R \cdot CX_2 \cdot CN + 2SO_2PhNa + 2H_2O = 2NaX + 2SO_2Ph \cdot OH + SO_2R \cdot CH_2 \cdot CN$.

The action of iodine dissolved in aqueous potassium iodide on the sodium salt of α-oximinobenzenesulphonylacetonitrile leads to the formation of the corresponding *potassium* salt, $SO_2Ph \cdot C(CN):NOK$, which crystallises in lustrous, golden-yellow leaflets.

The authors also record unsuccessful attempts to prepare compounds of the type $SO_2R \cdot C(CN):NO \cdot ONa$ by the condensation of ethyl nitrate and arylsulphonylacetonitriles by means of sodium ethoxide in alcoholic solution; in the case of *p*-chlorobenzenesulphonylacetonitrile, the product of the reaction consisted of the *sodium* salt,

$$C_6H_4Cl \cdot SO_2 \cdot CHNa \cdot CN.$$
F. B.

Spontaneous Formation of Iodonium Bases Containing Iodine in a Pentatomic Heterocyclic Nucleus. LUIGI MASCARELLI (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 617—620).—When 2 : 2'-di-iodosodiphenyl, $IO \cdot C_6H_4 \cdot C_6H_4 \cdot IO$, or 2:2'-di-iododiphenyl tetrachloride, $ICl_2 \cdot C_6H_4 \cdot C_6H_4 \cdot ICl_2$, are kept in water for some months, the aqueous solution yields diphenyleneiodonium iodide, $\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix} > I \cdot I$, when treated with sulphur dioxide. In the case of the tetrachloride, the di-iodoso-derivative is probably first formed, together with hydrogen chloride. By subsequent simultaneous oxidation and reduction of the di-iodoso-compound, all the following substances may be produced : $C_6H_4I \cdot C_6H_4I$, $IO_2 \cdot C_6H_4 \cdot C_6H_4 \cdot IO_2$, $C_6H_4I \cdot C_6H_4 \cdot IO_2$, $IO \cdot C_6H_4 \cdot C_6H_4 \cdot IO_2$, and $C_6H_4I \cdot C_6H_4 \cdot IO$. By rearrangement of the compound
$$IO \cdot C_6H_4 \cdot C_6H_4 \cdot IO_2,$$
diphenyleneiodonium iodate, $\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix} > I \cdot IO_3$, is produced, and this, by the action of sulphur dioxide, is reduced to the iodide (compare Forster and Schaeppi, T., 1912, 101, 1359).   R. V. S.
ωω'-Diarylated Aliphatic Hydrocarbons. WALTHER BORSCHE and J. WOLLEMANN (*Ber.*, 1912, 45, 3713—3725. Compare A., 1912, i, 23).—The method for the synthesis of αK-diphenyldecane has now been extended to the preparation of other members of the series, with certain modifications in the case of the pentane, heptane, and nonane.
Adipyl chloride, from adipic acid and phosphorus trichloride, condenses with benzene to form αζ-diphenylhexan-αζ-dione, m. p. 107° (Etaix, A., 1898, i, 124), δ-*benzoylvaleric acid*, $COPh \cdot [CH_2]_4 \cdot CO_2H$, being formed at the same time in white needles, m. p. 70—72°. The diketone has been converted into the dioxime, m. p. 222—223° (*ibid.*), which on reduction yields αζ-*diamino-αζ-diphenylhexane*,
$$NH_2 \cdot CHPh \cdot [CH_2]_4 \cdot CHPh \cdot NH_2,$$
as a colourless oil, b. p. 250—254°/16 mm., the *carbamide* of which, $C_{20}H_{26}O_2N_4$, melts at 121°, and the *benzoyl* derivative, $C_{32}H_{32}O_2N_2$, at 238°. The conversion of the diamine into Rupe and Bürgin's αζ-diphenyl-Δ$^{α-}$hexadiene (A., 1910, i, 161) gives a poor result, but the method of von Braun and Deutsch (A., 1912, i, 687) provides a better way of obtaining the desired αζ-diphenylhexane.

In the same way, suberyl chloride has been converted into the corresponding dioxime (Etaix, *loc. cit.*), and this has been reduced and the phosphate of the diamine has been distilled. A good yield of αθ-*diphenyl-Δ^{αη}-octadiene*, $CHPh:CH \cdot [CH_2]_4 \cdot CH:CHPh$, is thus obtained in colourless leaflets, m. p. 61—62°, b. p. 210—220°/11 mm. ; it gives a *tetrabromide*, $C_{20}H_{22}Br_4$, m. p. 196°, and absorbs hydrogen in the presence of palladium, yielding αθ-diphenyloctane (compare Braun and Deutsch, *loc. cit.*).

A characteristic derivative of αK-diphenyldecane (*loc. cit.*) is the nitration product, 2 : 4 : 2' : 4'-*tetranitro-αK-diphenyldecane*,
$$C_{10}H_{20}[C_6H_3(NO_2)_2]_2 ;$$
it forms yellowish-white needles, m. p. 63°.

The acid chlorides for the corresponding pentane, heptane, and nonane are difficult to obtain, and the diamines would probably yield ring compounds. Hence, the necessary ketones have been prepared by the reduction of available unsaturated ketones (compare A., 1912, i, 194) and reduced to alcohols, which, on dehydration with zinc chloride, give the olefines. The reduction of distyryl ketone to di-β-phenylethyl ketone is usually accompanied by by-products, the nature of which seems to depend on the condition of the palladium employed. The substance, $C_{34}H_{34}O_2$, m. p. 126° (*ibid.*), has not since been encountered ; instead, the $\alpha\epsilon\zeta\kappa$-tetraphenyldecane-$\theta$-dione, $C_{34}H_{34}O_2$, m. p. 173—174°, of Harries and Gollnitz (A., 1904, i, 427), and, apparently, its unsaturated *ketone*, $C_{34}H_{30}O_2$, a white powder, m. p. 207—208°, which dissolves with a purple colour in concentrated sulphuric acid, have been isolated. The required di-β phenylethyl ketone can be more conveniently prepared from phenylethyl methyl ketone by saturating its benzylidene compound (Harries and Gollnitz, *loc. cit.*) with hydrogen in presence of palladium. On reduction with sodium and alcohol, $\alpha\epsilon$-*diphenylpentan-γ-ol*, $OH \cdot CH(CH_2 \cdot CH_2Ph)_2$, is obtained as a very soluble, crystalline mass, m. p. 47—48°, b. p. 218°/11 mm., which, on distillation with zinc chloride, yields $\alpha\epsilon$-*diphenyl Δ^β-pentene* as a colourless oil, b. p. 184—185°/10 mm. Reduction readily results in the $\alpha\epsilon$ diphenylpentane of Braun and Deutsch (A., 1912, i, 435). The same series of reactions has also been carried out with phenyl δ-phenylbutyl ketone (A., 1912, i, 194), which has been obtained in colourless needles, m. p. 47°. $\alpha\epsilon$-*Diphenylpentan-α-ol*, $OH \cdot CHPh \cdot [CH_2]_3 \cdot CH_2Ph$, is a colourless oil, b. p. 217°/12 mm., which gives a poor yield of $\alpha\epsilon$-*diphenyl-Δ^α-pentene*, a colourless, mobile liquid, b. p. 186°/11 mm., which polymerises when heated. The $\alpha\epsilon$-diphenylpentane forms a *tetranitro*-derivative, $C_{17}H_{16}O_8N_4$, in slender, yellow needles, m. p. 126°.

$\alpha\eta$-Diphenylheptan-γ-one is best obtained by the reduction of $\alpha\eta$-*diphenyl-Δ^α-hepten-γ-one*, $CHPh \cdot CH \cdot CO \cdot [CH_2]_3 \cdot CH_2Ph$, which is formed in colourless leaflets, m. p 25°, b. p. 240°/12 mm., by the condensation of benzaldehyde with methyl-δ-phenylbutyl ketone (A., 1911, i, 880). Its reduction product, $\alpha\eta$-*diphenylheptan-γ-ol*, m. p. 42—43°, b. p. 233°/11 mm., is very readily dehydrated, and the heptene is also easily reduced to $\alpha\eta$ diphenylheptane, b. p. 207—208°/12 mm.

In the same way, $\alpha\iota$-diphenylnonan-ϵ-one (A., 1912, i, 194) has been reduced to $\alpha\iota$-*diphenylnonan-ϵ-ol*, a viscous, colourless liquid, b. p. 251°/11 mm., which yields the $\alpha\iota$-*diphenyl-Δ^δ-nonene* as a highly refractive oil, b. p. 231—233°/12 mm. Reduction of the latter to $\alpha\iota$-*diphenylnonane*, a colourless oil, b. p. 235°/12 mm., proceeds very readily.   J. C. W.

Pyrosulphates of Sodium and Potassium as Condensing Agents. ALLAN F. ODELL and CLEVE W. HINES (*J. Amer. Chem. Soc.*, 1913, 35, 81—84).—The alkali pyrosulphates have been used as condensing agents by Bogojavlenski and Narbutt (A., 1905, i, 854) in the preparation of certain esters. The salts are readily converted into the hydrogen sulphates by the addition of water, and should,

therefore, be efficient agents for the abstraction of water in organic synthesis ; they are easily prepared and convenient to handle.

The pyrosulphates have now been applied to the preparation of triphenylbenzene, benzylideneaniline, benzylidenemalonic acid, phenylstyryl ketone and acetanilide, and have given good results. They cannot be employed, however, to effect the condensation of phenols with other substances.   E. G.

Nitro-derivatives of *m*-Cresyl Oxide [*m*-Tolyl Ether]. ALPHONSE MAILHE (*Compt. rend.*, 1912, 155, 1524—1526).—A study of the nitration of *m*-tolyl ether prepared by the aid of thorium oxide (compare A., 1912, i, 767). Nitration in acetic acid solution at the ordinary temperature yields *nitro-m-tolyl ether,*

$$C_6H_4Me \cdot O \cdot C_6H_3Me \cdot NO_2,$$
b. p. 245—250°/50 mm., m. p. 48°, which on reduction with iron and acetic acid gives the corresponding *amine,* giving a violet coloration with calcium chloride. If during the nitration the temperature rises to 80—90°, *dinitro-m-tolyl ether,* $O(C_6H_3Me \cdot NO_2)_2$, prisms, m. p. 112°, is obtained, in which the nitro-groups are probably para to the oxygen.

By gradually adding tolyl ether to fuming nitric acid, kept cold, and then adding water, a paste is obtained, which, after extraction of the above dinitro-compound, is added to a mixture of sulphuric and nitric acids and yields 2 : 4 : 2′ : 4′-*tetranitro-m-tolyl ether,*
$$O[C_6H_2Me(NO_2)_2]_2,$$
a white, amorphous powder, m. p. 203°, which on boiling with concentrated aqueous potassium hydroxide yields *dinitrodihydroxy-m-tolyl ether,* a black, crystalline powder, m. p. 300° (decomp.).

If the original tolyl ether is nitrated in sulphuric acid solution by the gradual addition of fuming nitric acid, the temperature being gradually raised to 90° towards the end of the reaction, 2 : 6 : 2′ : 6′-*tetranitro-m-tolyl ether,* hexagonal plates, m. p. 147°, is obtained together with a large proportion of its isomeride. Attempts to carry the nitration further have, as yet, not been successful.   W. G.

Preparation and Oxidation of Styrolene Alcohol [Phenylethylene Glycol]. WM. LLOYD EVANS and LOU HELEN MORGAN (*J. Amer. Chem. Soc.*, 1913, 35, 54—68).—This investigation was undertaken with the object of determining the mechanism of the oxidation of phenylethylene glycol (styrolene alcohol) with different reagents, and of establishing the conditions under which mandelaldehyde might be isolated as an intermediate product. Zincke (*Annalen*, 1883, 216, 303) has shown that on oxidising the glycol with chromic acid, benzaldehyde, formaldehyde, and formic acid are produced, that with potassium permanganate a quantitative yield of benzaldehyde may be obtained, and that with nitric acid, benzoylcarbinol and benzoylformic acid are formed.
Phenylethylene glycol is best prepared by the hydrolysis of the corresponding diacetate (Zincke, *loc. cit.*). On oxidation with potassium permanganate, either alone or in presence of alkali hydroxide, it yields benzoic acid, but not phenylglyoxylic acid, the reaction taking place

in accordance with the equation: (1) $C_6H_5\cdot CH(OH)\cdot CH_2\cdot OH \longrightarrow$
$C_6H_5\cdot CHO + CH_3\cdot OH$ or
(2) $C_6H_5\cdot CH(OH)\cdot CH_2\cdot OH \longrightarrow C_6H_5\cdot CH_2\cdot OH + :CH\cdot OH.$
When the glycol is oxidised with potassium ferricyanide, benzoic
acid is the chief product, but mandelic acid is not formed, and the
reaction proceeds according to equation (1) or (2)   With silver oxide,
in presence of alkali hydroxide, the oxidation takes place, with formation
of benzoylcarbinol as the first product of the reaction, in one of the follow-

ing ways: (3) $C_6H_5\cdot CH(OH)\cdot CH_2\cdot OH \longrightarrow C_6H_5\cdot \overset{|}{C}\cdot CH_2\cdot OH + H_2O$;

and $C_6H_5\cdot \overset{|}{C}\cdot CH_2\cdot OH + H_2O \longrightarrow C_6H_5\cdot CO\cdot CH_2\cdot OH + 2H$;   or   (4)
$C_6H_5\cdot CH(OH)\cdot CH_2\cdot OH \longrightarrow C_6H_5\cdot CH(OH)\cdot CH: + H_2O$, and
$C_6H_5\cdot CH(OH)\cdot CH: + H_2O \longrightarrow C_6H_5\cdot CH(OH)\cdot CHO + 2H$;
at 60°, both reactions occur.   If silver oxide is employed alone at 20°,
the reaction seems to proceed entirely in accordance with equation (3).
The oxidation of phenylethylene glycol by bromine in presence of
potassium carbonate yields benzoylcarbinol.   Aqueous solutions of
copper salts do not exert any marked action on the glycol even
at 100°.   E. G.

Preparation of Benzyl Mercaptan.   JOHN A. SMYTHE (*Proc.
Univ. Durham, Phil. Soc.*, 1912, 4, !220—222).—Benzyl mercaptan
may be prepared from benzyl sulphide by reduction with iron filings in
acetic acid solution.   When dissolved in glacial acetic acid, and the
solution saturated simultaneously with hydrogen chloride and sulphur
dioxide, it yields benzyl disulphide and trisulphide in equal amounts.
   F. B.

Derivatives of Ethylene Dimercaptan, $SH\cdot CH_2\cdot CH_2\cdot SH$,
s-Dithiolethylene, $SH\cdot CH:CH\cdot SH$, and of Dithiolacetylene,
$SH\cdot C:C\cdot SH$.   EMIL FROMM, HANS BENZINGER, and FRITZ SCHAFER
(*Annalen*, 1912, **394**, 325—337).—s-*Diethylthiolethylene*,
                                        $SEt\cdot CH:CH\cdot SEt$,
b. p. 170°/13 mm., is obtained by the slow addition of dichloroethylene
to ethyl mercaptan and potassium hydroxide in alcohol, the mixture
being finally heated on the water-bath.   The addition of dichloro-
ethylene to benzyl mercaptan in boiling 7·5% alcoholic potassium
hydroxide yields s-*dibenzylthiolethylene*, $C_{16}H_{16}S_2$, m. p. 61°, colourless
needles, which decomposes by heating into hydrogen sulphide, toluene,
benzyl mercaptan, and stilbene, and forms a *dibromide*, $C_{16}H_{16}Br_2S_2$,
m. p. 73—74°, with bromine in carbon disulphide.   By heating with
alcoholic potassium hydroxide, this dibromide yields *dibenzylthiol-
acetylene*, $CH_2Ph\cdot S\cdot C:C\cdot S\cdot CH_2Ph$, m. p. 53°, straw-yellow needles or
flesh-coloured leaflets.
    s-*Dibenzylthiolethane*, $CH_2Ph\cdot S\cdot CH_2\cdot CH_2\cdot S\cdot CH_2Ph$, m. p. 38°, pre-
pared from ethylene dibromide and sodium benzyl mercaptide, is
oxidised by cold nitric acid (D 1·34) to the *disulphoxide*, $C_{16}H_{18}O_2S_2$,
m. p. 198°, white leaflets; the *disulphone*, $C_{16}H_{18}O_4S_2$, pearly leaflets
subliming at 304°, is obtained by oxidising the disulphoxide by
5% potassium permanganate, or the sulphide by chromic and acetic
acids.

s-*Di*-o-*nitrophenylthiolethylene*, $C_{14}H_{10}O_4N_2S_3$, m. p. 215°, golden-yellow leaflets, prepared from dichloroethylene, o-nitrophenyl mercaptan, and alcoholic potassium hydroxide, forms a *dibromide*,

$$C_{14}H_{10}O_4N_2Br_2S_2,$$
m. p. 132°, citron-yellow prisms, which is converted into *di*-o-*nitrophenylthiolacetylene*, m. p. 225°, yellow needles, by hot alcoholic potassium hydroxide. This acetylene derivative absorbs only one mol. of bromine in chloroform, forming *dibromodi*-o-*nitrophenylthiolethylene*, $C_2Br_2(S\cdot C_6H_4\cdot NO_2)_2$, m. p. 209°, yellow leaflets. Sodium o-nitrophenyl mercaptide and di-o-nitrophenylthiolethylene dibromide react in alcohol to form *glyoxaltetra*-o-*nitrophenylmercaptal*,

$$CH(S\cdot C_6H_4\cdot NO_2)_2\cdot CH(S\cdot C_6H_4\cdot NO_2)_2,$$
yellow needles, m. p. 178°.

s - *Di* - o - *aminophenylthiolethylene*, $C_2H_2(S\cdot C_6H_4\cdot NH_2)_2$, m. p. 67°, colourless leaflets, obtained by the reduction of the nitro compound by alkaline sodium hyposulphite, forms a *dibenzoyl* derivative, m. p. 132°, *diacetyl* derivative, m. p. 159°, and a sparingly soluble *dihydrochloride*, m. p. 201°; the last reacts with only one mol. of sodium nitrite during its diazotisation.

s-*Di*-o-*nitrophenylthiolethane*, $C_2H_4(S\cdot C_6H_4\cdot NO_2)_2$, m. p. 207°, yellow prisms, prepared by treating moist o-nitrophenyl mercaptan and ethylene dibromide with hot alcoholic potassium hydroxide, is oxidised to the *disulphoxide*, $C_{14}H_{12}O_6N_2S_2$, m. p. 145°, pale yellow needles, by chromic and warm glacial acetic acids, and to the *disulphone*, m. p. 164°, almost colourless prisms, by chromic and boiling glacial acetic acids, and yields s-*di*-o-*aminophenylthiolethane*, m. p. 74° (*dibenzoyl* derivative, m. p. 153°; *diacetyl* derivative, m. p. 194—195°), by reduction with tin and hydrochloric acid.

s-*Di*-p-*nitrophenylthiolethylene*, m. p. 126°, prepared like the ortho-isomeride, forms a *dibromide*, $C_{14}H_{10}O_4N_2Br_2S_2$, m. p. 137°, yellow needles, and yields by reduction the *diamino*-compound (*diacetyl* derivative, m. p. 194°), which can be readily tetrazotised. s-*Di*-p-*nitrophenylthiolethane*, m. p. 134°, crystallises in yellow prisms.

Di-2 : 4-*dinitrophenyl disulphide*, $S_2[C_6H_3(NO_2)_2]_2$, yellow needles, exploding at 280°, is obtained by heating alcoholic 2 : 4-dinitrochloro-benzene with aqueous sodium sulphide and sulphur.

2 : 4-Dinitrophenyl benzyl sulphide yields the *sulphoxide*,

$$C_6H_3(NO_2)_2\cdot SO\cdot CH_2Ph,$$

m. p. 144° (decomp.), straw-yellow needles, by oxidation with 30% hydrogen peroxide in glacial acetic acid, and the *sulphone*, m. p. 177°, by oxidation with chromic and warm glacial acetic acids.

2 : 4-*Dinitrophenyl methyl sulphide*, m. p. 126°, prepared from 2 : 4-dinitrophenyl mercaptan, methyl iodide, and methyl alcoholic sodium methoxide, yields the *sulphoxide*, m. p. 159°, yellow leaflets, and the *sulphone*, m. p. 184° (decomp.), colourless needles, by oxidation with hydrogen peroxide and chromic acid respectively.   C. S.

Decomposition of Benzyl Disulphide by Alkalis. EMIL FROMM and AQUILA FORSTER (*Annalen*, 1912, 394, 338—343).—In addition to the substances identified by Price and Twiss among the products of decomposition of benzyl disulphide by alkalis (T., 1910, 97,

1175), the authors have detected thiobenzoic acid and dithiobenzoic acid. *Benzyl dithiobenzoate*, $Ph \cdot CS_2 \cdot CH_2Ph$, m. p. 55°, is prepared by heating the acid and benzyl chloride with alcohol and 10% sodium hydroxide.

When the preceding decomposition is effected in the presence of benzyl chloride, the authors could obtain only about 5% of the benzyl-mercaptal of benzaldehyde instead of 50%, as stated by Price and Twiss (*loc. cit.*), and they suggest that the latters' benzyl chloride was highly contaminated with benzylidene chloride, which reacts with the sodium benzyl mercaptide to form the benzylmercaptal.

[With MAX KLINGER.]—The substance, m. p. 164°, obtained by Fromm and Schmoldt by the dry distillation of benzoyl sulphide, benzoyl disulphide, or thiobenzoic acid, and stated to be tolane tetra-sulphide (A., 1907, i, 702), is now shown to be a mixture. By treatment with ammonium sulphide or with ether and petroleum, it is separated into sulphur and tetraphenylthiophen, m. p. 184°. The substance described as tolane disulphide (*loc. cit.*) is probably also a mixture of sulphur and tetraphenylthiophen.   C. S.

Some Mercaptals and Mercaptols and their Derivatives. EMIL FROMM, AQUILA FORSTER, and BORIS VON SCHERSCHEWITZKI (*Annalen*, 1912, 394, 343—349).—The *benzylmercaptal* of formaldehyde, $CH_2(S \cdot CH_2Ph)_2$, m. p. 55°, obtained by saturating with hydrogen chloride a solution of benzyl mercaptan and excess of 40% formaldehyde in glacial acetic acid, is oxidised to the *sulphoxide*, $CH_2(SO \cdot CH_2Ph)$, m. p. 189°, by hydrogen peroxide and to the *sulphone*, $CH_2(SO_2 \cdot CH_2Ph)_2$, m. p. 216°, by acidified 5% potassium permanganate. The *benzylmercaptal* of acetaldehyde,

$$CHMe(S \cdot CH_2Ph)_2,$$

b. p. 200—205°/5 mm., is oxidised to the *sulphone*, $CHMe(SO_2 \cdot CH_2Ph)_2$, m. p. 176°, by 5% potassium permanganate.

The *benzylmercaptole* of acetone, $CMe_2(S \cdot CH_2Ph)_2$, b. p. 195°/5 mm., yields the *sulphoxide*, m. p. 105°, and *sulphone*, m. p. 125°, by oxidation as above. This sulphone and also αα-dibenzylsulphone-ethane are produced when dibenzylsulphonemethane is heated with alcoholic methyl iodide and aqueous sodium hydroxide. When αα-dibenzylsulphonepropane is similarly treated, benzylmethylsulphone is obtained, owing to the intermediate formation of benzylsulphinic acid. The following substances are also described : the p-*tolylmercaptal* of formaldehyde and its *sulphoxide*, m. p. 45°, and *sulphone*, m. p. 135°; the p-*tolylmercaptole* of acetone, m. p. 64—65°, and its *sulphoxide*, m. p 75—76°, and *sulphone*, m. p. 147—148°; αα-*di* p-*tolylsulphone-ethane*, m. p. 156°, and αα-*di-p-tolyl-sulphonepropane*, m. p. 189°.   C. S.

Catalysis of Dehydrogenation of Hexahydrobenzoic [*cyclo*-Hexanecarboxylic] Acid. NICOLAI D. ZELINSKI and N. UKLONSKAJA (*Ber.*, 1912, 45, 3677—3678).—An extension of the process which proved successful with *cyclo*hexane and its methyl derivative to simple derivatives which are not hydrocarbons (Zelinski, A., 1911, i, 958).

When *cyclo*hexanecarboxylic acid is added gradually to palladium

black at 300° in an atmosphere of hydrogen at 20—25 mm. pressure, the vapours which pass away on condensation give crystals of benzoic acid in a smaller quantity of unchanged liquid *cyclo*hexanecarboxylic acid.

If ethyl *cyclo*hexanecarboxylate (b. p. 195—197°, n^{17} 1·4424) is submitted twice to the above treatment, the liquid product can be separated by distillation into two fractions, the smaller one consisting of a mixture of ethyl benzoate and ethyl benzoate (n^{18} 1·5071), whilst the main fraction is of pure ethyl *cyclo*hexanecarboxylate. The progress of the dehydrogenation can be conveniently followed by the change in the refractive index.

As with *cyclo*pentane and its methyl derivative, no dehydrogenation was observed when methyl*cyclo*pentanecarboxylic acid was treated in a similar manner. D. F. T.

Study of Double Linkings. ANTONIO MADINAVEITIA and JOSÉ SUREDA BLANES (*Anal. Fis. Quim.*, 1912, 10, 381—389).—Under the influence of platinum black, cinnamic acid in glacial acetic acid solution is fully hydrogenised to Zelinski's *cyclo*hexylpropionic acid, whilst palladium black and colloidal palladium determine reduction to phenyl-propionic acid. *Octahydroeugenole*, prepared by the hydrogenation of eugenole with platinum black as catalyst, has b. p. 125° at 12 mm., and forms an oil soluble in acetic acid, alcohol and ether, and insoluble in water and light petroleum. In the presence of palladium black, eugenole is reduced to hydroeugenole. G. D. L.

Some Para-derivatives of Phenylacetic Acid. S. ROBSON (*Proc. Univ. Durham Phil. Soc.*, 1912, 4, 225—227).—*p*-Bromophenyl-acetic acid, m. p. 114—115°, has been prepared from *p*-nitrophenyl-acetonitrile by reduction with stannous chloride, followed by replace-ment of the amino-group by bromine by means of the diazo-reaction, and finally hydrolysing the resulting *p*-bromophenylacetonitrile, m. p. 112°, with sulphuric acid; on nitration it yields 4-bromo-3-nitro-phenylacetic acid (Bedson, T., 1880, 37, 100).

p-Chloro- and *p*-iodo-phenylacetic acids have been prepared in a similar manner. F. B.

Walden's Inversion and Substitution Processes. II. EMIL FISCHER (*Annalen*, 1912, 394, 350—362. Compare A., 1911, i, 418). —Mainly a reply to Biilmann (A., 1912, i, 420) and to Noyes and Potter (*ibid.*, 786).

Phenylpropiolic acid is reduced to cinnamic acid by zinc dust in alkaline as well as in acid solution (compare A., 1912, i, 187); conse-quently, the presence of the acid is not the cause of the presumably abnormal course of the reduction. C. S.

Behaviour Towards Light of Cinnamylideneacetonitrile of α-Phenylcinnamylideneacetic Acid, and of the Two Cinn-amylideneacetic Acids. HANS STOBBE [and NICOLAUS BARBA-SCHINOV] (*Ber.*, 1912, 45, 3396—3408).—When the dark yellow

α-phenylcinnamylideneacetonitrile, $CHPh\!:\!CH\cdot CH\!:\!CPh\cdot CN$, is exposed to light in benzene or chloroform solution, a resin is formed, together with benzoic acid and a colourless dimeride, $C_{34}H_{26}N_2$, m. p. 197°. It thus behaves very similarly to cinnamylidenemalonic acid (Rüber, A., 1902, i, 617), which is polymerised by light to diphenyltetramethyl-enediethenyldicarboxylic [diphenyl*cyclo*butyldiacrylic] acid. The dimeride, when cautiously oxidised by potassium permanganate in aqueous alkaline methylacetate solution, is converted into benzoyl cyanide and α-truxillic acid, $CO_2H\cdot CH{<}^{CHPh}_{CHPh}{>}CH\cdot CO_2H$. This establishes the dimeride as 1 : 3-*diphenyltetramethylene*-2 : 4-*diethenyl-β-phenyl-β-cyanide* [1 : 3-*diphenylcyclobutane*-2 : 4-*diatroponitrile*],

$$CN\cdot CPh\!:\!CH\cdot CH{<}^{CHPh}_{CHPh}{>}CH\cdot CH\!:\!CPh\cdot CN.$$

It combines with bromine to a colourless tetrabromide, indicating the absence of a conjugated double bond system, whereas phenylcinnamyl-idene acetic acid forms only a colourless dibromide. The polymerisation of the cyanide is accompanied by bleaching, the absorption field of the dimeride being displaced some 800 wave-lengths towards the ultra-violet.

On heating at 200°, the dimeride is depolymerised, yielding simply unimolecular cyanide. This behaviour, which is shared by α-truxillic acid, is not in accordance with that of other *cyclo*butane derivatives, and throws some uncertainty on the four-ring formulæ adopted.

A second colourless dimeride, m. p. 215°, is formed during exposure to light. This is also produced as a by-product of the action of bromine on the first dimeride. It does not unite with bromine, and it is not so easily depolymerised ; the constitution has not been determined.

α-Phenylcinnamylideneacetic acid, whether used in the form of the acid, its sodium salt or methyl ester, is stable towards light in the absence of oxygen, but in presence of air it is oxidised to benzalde-hyde and benzoic acid. No polymerisation product is formed. The methyl ester is more readily oxidised than the acid, whilst the sodium salt is still more resistant.

Similarly under no conditions could a polymeride be obtained from the isomeric cinnamylideneacetic acids. Some oxidation takes place, also the *allo*-acid is converted into its isomeride.

The dimeric acid, $C_{22}H_{20}O_4$, obtained by Rüber (*loc. cit.*) on heating the dimeride of cinnamylidenemalonic acid could not be depolymerised to cinnamylideneacetic acid. The sodium salt and methyl ester behave similarly to the acid ; the ester is more easily oxidised under the influence of light ; the salt is more stable than the acid. The different behaviour of the compounds studied is not due to any differences in the selective absorption of light by them.

The *dibromide*, $C_{17}H_{13}NBr_2$, from phenylcinnamylideneacetonitrile, crystallises in colourless needles, m. p. 118°. The *tetrabromide* $C_{34}H_{26}N_2Br_4$, of the dimeride has m. p. 276°.

Cinnamylidenemalonic acid forms a *dibromide*, $C_{12}H_{10}O_4Br_2$, m. p. 180°. The *tetrabromide* of the dimeride has decomp. above 100°.

Methyl allo*cinnamylideneacetate* is an oil, solidifying below $-80°$.

E. F. A.

Some Pharmaceutical Incompatibilities of Salol [Phenyl Salicylate]. ITALO BELLUCCI (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 610—616. Compare Caille, A., 1909, i, 594).—In pharmaceutical practice it is not infrequently observed that two dry, solid drugs yield a pasty or liquid mixture. This phenomenon is not due in all cases to the occurrence of a chemical reaction, but results in some cases from the formation of an eutectic mixture of low m. p. In the present paper the author gives tables and curves which exhibit the results of the thermal analysis of the binary mixtures of salol with the substances mentioned in the following list:
	Eutectic.			Eutectic.	
	Temp.	% Salol.		Temp.	% Salol.
β-Naphthol	34°	90	Chloral hydrate .	17°	61
Antipyrine	30	83	Thymol	13	66
Urethane	29	86	Camphor	6	56
Menthol	28	45	Guaiacol	3	53
β-Bromocamphor.,	21	64			

In the system salol-menthol there is complete miscibility in the solid state, the curve being Roozeboom's type III. with a minimum at about 28° and 45% of salol. From the temperature given it follows that some of the above binary mixtures are pasty at ordinary temperatures, others liquid. R. V. S.
Condensation of Cyclic Ketones with Ethyl Oxalate. ARTHUR KOTZ, K. BLENDERMANN, and J. MEYER (*Ber.*, 1912, 45, 3702—3705. Compare A., 1906, 88, 668).—Active 1-methyl*cyclo*hexan-3-one condenses in the cold with ethyl oxalate and sodium ethoxide, and when the dry product is treated with methyl iodide and subsequently hydrolysed, 1 : 4-dimethyl*cyclo*hexan-2-one is obtained, b. p. 51°/ 10 mm. Its *oxime*, $C_8H_{15}ON$, has m. p. 97—98°.

Inactive 1-methyl*cyclo*hexan-2-one condenses to form a *methylcyclohexenolpyruvolactone*, $C_9H_{10}O_3$, m. p. 141°, alcohol being eliminated. When this is treated with methyl iodide, a *dimethyl* compound, $C_{10}H_{12}O_3$, m. p. 87°, is formed, which absorbs 4 atoms of hydrogen and yields 1-methyl*cyclo*hexan-2-one on hydrolysis. Since these compounds give no reactions for ketones, and since Claisen has shown that the formation of lactones is possible in such circumstances (A., 1895, i, 373), they may be represented by the annexed formulæ. J. C. W.

Melting Point of Ethyl Gallate. HENRY C. BIDDLE (*J. Amer. Chem. Soc.*, 1913, 35, 96).—Biddle and Kelley (A., 1912, i, 714) suggested that the peculiar behaviour of ethyl gallate on melting might be due to the existence of two crystalline forms. It has now been found, however, that by continued purification the ester can

be obtained in long, colourless needles, melting fairly sharply at 160°.

<div align="right">E. G.</div>

Kojic Acid, a New Organic Acid Formed by Aspergillus oryzæ. T. YABUTA (*J. Coll. Agric. Imp. Univ. Tokyo*, 1912, **5**, 51—58).—*Kojic acid*, $C_{10}H_6(OH)_4(CO_2H)_2$, obtained from finely powdered *Aspergillus oryzae*, forms colourless needles or prisms, m. p. 152°. The acid gives a strong red colour with ferric chloride; it has no action on alkaline diazobenzenesulphonic acid, on Millon's reagent, or on Fehling's solution. The aqueous solution absorbs much bromine. Methoxyl and ethoxyl groups are not present. The *copper* salt, $C_{12}H_{12}O_8Cu$, forms light green, rhombic crystals. The *acetyl* derivative, $C_{12}H_{10}O_4(OAc)_4$, crystallises from alcohol in colourless needles, m. p 102°. The *dibenzoyl* derivative, $C_{12}H_{10}O_4(OH)_2(OBz)_2$, m. p. 137°, and the *tetrabenzoyl* derivative, $C_{12}H_{10}O_4(OBz)_4$, m. p. 135°, were prepared.

The acid also occurs in *Aspergillus albus, A. candidus*, and *A. nidulans*, but was not found in thirteen other varieties or in *Penicillium* or *Mucor*.

The production of the acid seems to depend on the food supplied to the *Aspergillus*. It was found in *Aspergillus* grown on certain cereals and potatoes, but not with leguminous seeds.

<div align="right">N. H. J. M.</div>

Synthesis of β-Glucosidogallic Acid. EMIL FISCHER and HERMANN STRAUSS (*Ber.*, 1912, **45**, 3773—3779).—Ethyl gallate combines with acetobromoglucose, forming *ethyl tetra-acetylglucosidogallate*, which is completely hydrolysed by cold barium hydroxide solution to *glucosidogallic acid*, $C_6H_{11}O_5 \cdot C_6H_2(OH)_2 \cdot CO_2H$. This crystallises in colourless, interlaced needles, m. p. 193° (decomp.), after sintering from 155°, $[\alpha]_D^{20} - 22°$. It is monobasic and is hydrolysed by emulsin into dextrose and gallic acid. With ferric chloride a brownish-red coloration is produced, indicating that the *p*-hydroxyl group of the gallic acid is attached to the sugar residue. It differs from the supposed glucosides of gallic acid described by Gibson (A., 1903, i, 355) and by Feist (A., 1912, i, 566, 888).

Ethyl tetra-acetylglucosidogallate crystallises in colourless needles, m. p. 180—181° (corr.), $[\alpha]_D^{20} - 10 \cdot 6°$.

<div align="right">E. F. A.</div>

Some Reduction Products of Ellagic Acid. MAXIMILIAN NIERENSTEIN and FREDERIC W. RIXON (*Annalen*, 1912, **394**, 249—258). —The electrolytic reduction of ellagic acid in a divided cell with mercury cathode and nickel anode yields different products at different temperatures. By reduction in $4N$-sodium hydroxide at the ordinary temperature, ellagic acid yields chiefly *leucoellagic acid*,

$$C_6H(OH)_2 \underset{O \cdot CH(OH)}{\overset{CH(OH) \cdot O}{<}} \rangle C_6H(OH)_2,$$
m. p. 294—296° (decomp.), small needles. This substance is colourless, does not possess any tinctorial properties, forms a *hexa-acetyl* derivative, m. p. 272—275° (decomp.), and a *hexabenzoyl* derivative, m. p. 300—305° (decomp.), and is reconverted into ellagic acid by oxidation with hydrogen peroxide. By boiling with aqueous potassium hydroxide and carbon tetrachloride, leucoellagic acid is converted into the

potassium salt, long rhombohedra, of the *dicarboxylic acid*,

$$CO_2H \cdot C_6(OH)_2 \overset{CH(OH) \cdot O}{\underset{O \cdot CH(OH)}{<}{>}} C_6(OH)_2 \cdot CO_2H,$$
m. p. 123—124° (decomp.), small needles. A solution of the dicarboxylic acid in ethyl acetate has been separated by strychnine into the two (impure) active acids and the meso-modification. The impure d-*acid* has m. p. 122—124° and $[\alpha]_D^{17} +19 \cdot 9°$; the impure l-*acid* has m. p 127—131° and $[\alpha]_D^{17} - 2 \cdot 3°$, and the meso-*acid* has m. p. 143—146° (decomp.).

The electrolytic reduction of ellagic acid in alkaline solution at 70° yields pentahydroxydiphenylmethylolide (A., 1908, i, 548), whilst its reduction in concentrated sodium hydroxide at 110° yields 2 : 3 : 4 : 2' : 3' : 4'-hexahydroxydiphenyl. C. S.

New Basic Component of the Muscle of the Dog and Its Relation to Hexamethylornithine. DANKWART ACKERMANN (*Zeitsch. Biol.*, 1912, 59, 433—440).—*Myokynine*, a basic substance obtained from dog's muscle, is probably *l*-hexamethylornithine. Both substances give precipitates with phosphotungstic acid and with alcoholic mercuric chloride solution.

The *aurichloride* from myokynine contains $2H_2O$ and is lævorotatory, that from *hexamethylornithine*, m. p. 201—205°, is anhydrous. Myokynine *platinichloride* $(2H_2O)$ has m. p. 232—234°; the isomeride (H_2O) has m. p. 232—233°.

Hexamethylornithine is obtained from ornithine by means of methyl sulphate ; it is dextrorotatory. E F. A.

The Bromination of cycloPentanone. MARCEL GODCHOT and FÉLIX TABOURY (*Compt. rend.*, 1912, 155, 1522—1524).—When bromine (4 mols.) dissolved in carbon tetrachloride is added to a solution of cyclopentanone (1 mol.) in the same solvent, either with or without the presence of aluminium bromide, the mixture being kept cold, there is obtained, on evaporating off the solvent, an abundant crop of crystals with more or less oil. The crystals are separated, and on purification yield *tetrabromocyclopentanone*, $C_5H_4OBr_4$, large plates, m. p. 99°. It is very soluble in ether, ethyl acetate, etc., and when left to itself slowly loses hydrogen bromide and is converted into a yellow oil. This change takes place rapidly in solution in ethyl acetate, and the product when purified is *tribromocyclopentanone*, $C_5H_3OBr_3$, colourless prisms, m. p. 57—58°. This substance on bromination in carbon tetrachloride solution adds on two atoms of bromine, giving *pentabromocyclopentanone*, $C_5H_3OBr_5$. m. p. 93°.

The oil obtained in the original bromination slowly loses hydrogen bromide, and on boiling the product with water and extracting with ether, a *compound* is obtained, m. p. 147°, which analysis shows to be either $C_5H_3O_2Br$ or $C_5H_5O_2Br$, the amount of material to hand not allowing of definite distinction between the two formulæ. The substance functions both as an alcohol and a ketone. W. G.

2 : 2-Dimethylcycloheptanone. P. JOSEPH TARBOURIECH (*Compt. rend.*, 1913, 156, 75—77).—The dehydration of cyclohexanoldimethylcarbinol gives rise to a hydrocarbon, C_9H_{14}, and two isomeric ketones,

$C_9H_{16}O$, one of which has been shown to be 1-acetyl-1-methyl*cyclo*hexane (compare A., 1910, i, 557), and the other is now proved to be 2 : 2-*dimethyl*cyclo*heptanone*, $Me_2C{<}^{CH_2 \cdot CH_2 \cdot CH_2}_{CO-CH_2-CH_2}$, the :CO group having been introduced into the hexatomic ring. By purification through its oxime, it is obtained as a colourless liquid, b. p. 82°/ 18 mm., giving a *carbanilino-oxime*, m. p. 94°, and a *semicarbazone*, m. p. 176°. On oxidation with weak alkaline permanganate, it yields *α-keto-ββ-dimethylpimelic acid*, $CO_2H \cdot CO \cdot CMe_2 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CO_2H$, m. p. 67°, giving a *semicarbazone*, m. p. 185°, and an *oxime*, m. p. 140—141°, which on heating further decomposes, losing carbon dioxide and water, giving *δ-cyano-δδ-dimethylpentoic acid*,
$$CN \cdot CMe_2 \cdot [CH_2]_3 \cdot CO_2H,$$
m. p. 34—35°, which on hydrolysis with alcoholic potassium hydroxide is converted into *αα*-dimethyladipic acid.   W. G.

Electrolysis of *cyclo*Pentanone. MARCEL GODCHOT and FÉLIX TABOURY (*Bull. Soc. chim.*, 1913, [iv], 13, 12—17. Compare A., 1912, i, 34, 552).—On electrolysis in alkaline solution, *cyclo*pentanone yields *cyclo*pentylidene*cyclo*pentanone (Wallach, A., 1897, i, 160) and two other products, which appear to be tetra*cyclo*pentane derivatives. It is probable that the *cyclo*pentylidene*cyclo*pentanone is formed by the condensation of two mols. of *cyclo*pentanone in presence of alkali, and that the other two products are formed from the condensation product by electrolytic action, the first being the corresponding pinacone and the second the corresponding pinacolin. These supposed tetra*cyclo*pentane derivatives have the following characters. The first, m. p. 160—162°, has the formula $C_{20}H_{30}O_2$, and is probably identical with the substance obtained by Meiser (A., 1899, i, 741).

$CH_2 \cdot CH_2{>}C{:}C{<}^{CH_2—CH_2}_{C(OH) \cdot CH_2}$
$CH_2 \cdot CH_2$

$CH_2 \cdot CH_2{>}C{:}C{<}^{C(OH) \cdot CH_2}_{CH_2—CH_2}$
$CH_2 \cdot CH_2$

It probably has the annexed constitution, which makes it the pinacone corresponding with *cyclo*pentylidene*cyclo*pentanone. This substance probably loses 1 mol. of water, giving rise to the second *product*, $C_{20}H_{28}O$, b. p. 320°/25 mm., a yellow liquid which gives no typical carbonyl derivatives, although it probably has the following constitution, being formed in a manner analogous to the transformation of the pinacone of *cyclo*pentanone into the corresponding pinacolin (Meiser, *loc. cit.*), $^{CH_2—CH_2}_{CH_2 \cdot C(C_5H_8)}{>}C{<}^{CH_2—CH_2}_{CO \cdot C(C_5H_8)}{>}CH_2$.
                                                                T. A. H.

Terpenes and Ethereal Oils. CXII. Condensation Products of Cyclic Ketones and Acetone. OTTO WALLACH and WOLFGANG VON RECHENBERG (*Annalen*, 1912, 394, 362—384).— Many years ago a substance, $C_{10}H_{16}O$, isomeric with pulegone, was obtained by the condensation of acetone and methyl*cyclo*hexan-3-one, but its constitution could not be definitely settled (A., 1896, i, 310 ; 1898, i, 484). An extensive examination of similar condensations now leads to the generalisation that the acetone attacks the carbonyl group of *cyclo*hexanones, but a nuclear methylene group of *cyclo*-

pentanones; thus equal molecular quantities of *cyclo*pentanone and acetone are kept in alcoholic sodium ethoxide for some hours at 0°, and then for two to three days at the ordinary temperature, whereby, in addition to a little mesityl oxide, *propylidenecyclopentan 2-one*,

$$CMe_2{:}C\overset{CO-CH_2}{\underset{CH_2\cdot CH_2}{<}},$$
b. p. 195—199°, D^{20} 0·9565, n_D^{20} 1·4932, is obtained (*semicarbazone*, m. p. 215—218°; *oxime*, m. p. 77°), by the reduction of which by hydrogen and colloidal palladium, iso*propyl*cyclo*pentan-2-one*, b. p. 176·5—177·5°, D^{21} 0·9000, n_D^{21} 1·4419 (*semicarbazone*, m. p. 197°; *benzylidene* derivative, m. p. 79—80°), is formed. In a similar manner, i-*methyl*cyclo*pentan-3-one*, b. p. 144—144·5°, D^{22} 0·913, n_D 1·4329 (*semicarbazone*, m. p. 185°, *benzylidene* derivative, m. p. 157°; m-*nitrobenzylidene* derivative, m. p. 174°; *anisylidene* derivative, m. p. 197—198°; *piperonylidene* derivative, m. p. 166—167°; *cinnamylidene* derivative, m. p. 148° [compare A., 1904, i, 752; 1908, i, 424]), prepared from i-β-methyladipic acid, condenses with acetone to form 1-*methyl-4-propylidene*cyclo*pentan-3-one*,　$CMe_2{:}C\overset{CH_2\cdot CHMe}{\underset{CO-CH_2}{<}}$, b. p.

203—205°, D^{21} 0·9315, n_D^{21} 1·4846 (*semicarbazone*, m. p. 210°; *oxime*, m. p. 89°). The constitution of this compound is determined by its exalted molecular refraction, and by the fact that 1-*methyl*-4-iso*propyl*-cyclo*pentan-3-one*, b. p. 186—187°, D^{20} 0·8850, n_D^{20} 1·4392 (*semicarbazone*, m. p. 179°; *oxime*, m. p. 66°), obtained from it by Paal's method, yields by oxidation with chromic and dilute sulphuric acids a *keto-acid*, $CHMe_2\cdot CO\cdot CH_2\cdot CHMe\cdot CH_2\cdot CO_2H$ (*semicarbazone*, m. p. 164°; *oxime*, m. p. 76—77°), by the further oxidation of which i-β-methylglutaric acid is produced.

*cyclo*Hexanone and acetone condense to form Δ¹-cyclo*hexenylacetone*, $C_6H_9\cdot CH_2\cdot COMe$, b. p. 203—204°, D^{19} 0·9375, n_D 1·4736 (*semicarbazone*, m. p. 144—145°; *oxime*, b. p. 135°/20 mm.), the constitution of which follows from its molecular refraction and from its reduction by Paal's method to *cyclo*hexylacetone, m. p. 171—172° (not 165—166°, A., 1907, i, 616). *cyclo*Hexyl*trimethylcarbinol*, $C_6H_{11}\cdot CH_2\cdot CMe_2\cdot OH$, b. p. 208°, D^{20} 0·902, n_D^{20} 1·4627, is prepared from *cyclo*hexylacetone and magnesium methyl iodide in the usual manner.

Methyl*cyclo*hexan-4-one and acetone yield 1-*methyl*-Δ³-cyclo*hexenyl*-4-*acetone*, $C_6H_8Me\cdot CH_2\cdot COMe$, b. p. 216—217°, D^{21} 0·916, n_D^{21} 1·4672 (*semicarbazone*, m. p. 122—123°), by the reduction of which 1-*methyl*-cyclo*hexyl*-4-*acetone*, b. p. 214—215°, D^{21} 0·8930, n_D^{21} 1·4499 (*semicarbazone*, m. p. 166°), is formed.

The compound $C_{10}H_{16}O$, obtained from active methyl*cyclo*hexan-3-one and acetone (*loc. cit.*), is now proved to be 1-*methyl*-Δ²⁽ᵒʳ ³⁾-cyclo*hexenyl-3-acetone*, $C_6H_8Me\cdot CH_2\cdot COMe$, or a mixture of both. By reduction by Paal's method, it yields 1-*methyl*cyclo*hexyl-3-acetone*, $C_6H_{10}Me\cdot CH_2\cdot COMe$, b. p. 212—214°, $D^{21·5}$ 0·8915, $n_D^{21·5}$ 1·4496 (*semicarbazone*, m. p. 154°), which is converted by alkaline hypobromite into 1-methyl*cyclo*hexyl-3-acetic acid, and by magnesium methyl iodide ultimately into 1-*methyl*cyclo*hexyltrimethylcarbinol*,

$$C_6H_{10}Me\cdot CH_2\cdot CMe_2\cdot OH,$$
b. p. 117°/20 mm. (*phenylurethane*, m. p. 126°). By the elimination of water, the carbinol yields a *hydrocarbon*, $C_{11}H_{20}$, b. p. 186·5—187 5°, D^{20} 0·8120, n_D^{20} 1·4546. *i*-Methyl*cyclo*hexan-3-one condenses with acetone in the same manner as the active substance, yielding a *compound*, $C_{10}H_{16}O$, b. p. 214—217°, D^{21} 0 918, n_D 1·4704 (*semicarbazone*, m. p. 150—151°).

1-Methyl*cyclo*hexan-2-one and acetone, after keeping with alcoholic sodium ethoxide for four weeks, yield mesityl oxide and 1-*methyl*-Δ^1-*cyclo*hex*enyl-2-acetone*, b. p. 216—217°, D^{19} 0 936, n_D^{19} 1·4778 (*semi carbazone*, m. p. 173—174°); the latter yields by reduction by Paal's method, 1-*methylcyclohexyl-2-acetone*, b. p. 212—214°, D^{21} 0·9050, n_D^{21} 1·4546 (*semicarbazone*, m. p. 179°), from which 1-*methylcyclohexyl-2-acetic acid* (*silver* salt, $C_9H_{15}O_2Ag$; *amide*, m. p. 160—161°) is obtained by oxidation by alkaline hypobromite.   C. S.

Studies in the *cyclo*Pentadiene Series. II. 5-Nitro-2:3 dibenzoyl*cyclo*pentadiene. WILLIAM J. HALE and LAMBERT THORP (*J. Amer. Chem. Soc*, 1913, 35, 68—75).—It has been shown by Hale (A., 1912, i, 566) that acetonylacetone condenses with nitromalonaldehyde to form 5-nitro-2 : 3-diacetyl*cyclo*pentadiene. A similar condensation has now been effected with diphenacyl.

When diphenacyl (1 mol.) is added to a solution of sodium nitromalonaldehyde (1 mol.) and sodium hydroxide (2 mols.), and the mixture is left for eight to ten days at 40°, 5-*nitro*-2 : 3-*dibenzoyl*cyclo-*pentadiene*, $NO_2 \cdot CH \Big\langle{}^{CH:CBz}_{CH:CBz}$, m. p. 237—238° (decomp.), is obtained in a yield of 75% of that calculated from the amount of aldehyde used. The compound crystallises in yellow prisms; its *sodium*, *barium*, and *silver* salts are described. The *oxime*, m. p. 155—156° (decomp.), and the *anil*, m. p. 264—265°, form slender, yellow needles. The *phenyl-hydrazone* crystallises in yellow needles; it is unstable and readily undergoes an intramolecular condensation.

If 5-nitro-2 : 3-dibenzoyl*cyclo*pentadiene is boiled with dilute nitric acid, it undergoes oxidation with production of carbon dioxide, oxalic acid, and benzoic acid. A similar result is obtained by means of an alkaline solution of potassium permanganate, 1 mol. of the compound yielding carbon dioxide (3 mols.), oxalic acid (1 mol.), nitric acid (1 mol.), and benzoic acid (2 mols.).   E. G.

Thio-derivatives of Ketones. EMIL FROMM (*Annalen*, 1912, 394, 290—309).—[WITH FRITZ HAAS.]—The substance previously described as duplobenzylidenethioacetone by Fromm and Höller (A., 1907, i, 710) is now shown to be a mixture of stereoisomeric bases, the *duplobenzylidenethioacetoneamines*, $C_{20}H_{23}NS_2$, and its extraordinary additive compounds with acids are simply salts of these bases; consequently, the theories advanced by Fromm and Höller to explain the formation of these additive compounds are abandoned. The *hydro-chloride*, $C_{20}H_{23}NS_2,HCl$, has m. p. 238°, the *sulphate* has m. p. 192°, and the *nitrate* has m. p. 211°. The substance previously described as duplobenzylidenethioacetone hydrate, and the two additive compounds

with ammonia, m. p. 142° and 148° respectively, are simply duplo-benzylidenethioacetoneamine.

The neutral by-product, duplobenzylideneoxythioacetone, m. p. 186°, obtained by Fromm and Höller in the preparation of their so-called duplobenzylidenethioacetone (*loc. cit.*), becomes the main product when sodium sulphide is employed instead of ammonium sulphide. It is now shown to be *duplobenzylideneacetone sulphide*, $C_{20}H_{22}O_2S$. It forms a *dibromo*-derivative, $C_{20}H_{20}O_2SBr_2$, m. p. 164°, rhombic leaflets, with bromine in chloroform, and is oxidised by 5% potassium permanganate, by fuming nitric acid, or by 30% hydrogen peroxide in glacial acetic acid, to *duplobenzylideneacetone sulphoxide*, $C_{20}H_{22}O_3S$, m. p. 308°, prisms, which forms a *dibromo*-derivative, $C_{20}H_{20}O_3SBr_2$, m. p. 214°, felted needles, with bromine. By treating a not too concentrated solution of styryl methyl ketone in alcohol with ammonium poly-sulphide, *duplobenzylideneacetone disulphide*, $C_{20}H_{22}O_2S_2$, m. p. 125°, is obtained.

Since duplobenzylidenethioacetoneamine yields hydrogen sulphide, ammonia, and styryl methyl ketone-phenylhydrazone by treatment with phenylhydrazine at a temperature not exceeding 140—150°, it probably has the formula $NH[OMe(SH)\cdot CH\colon CHPh]_2$, despite its insolubility in alkalis. Moreover, since it yields duplobenzylidene-acetone disulphide by oxidation by hydrogen peroxide or by iodine, the disulphide probably has the formula $S_2[CMe(OH)\cdot CH\colon CHPh]_2$. By moistening with a little alcohol and then shaking with dilute sodium hydroxide, the disulphide is converted into the sulphide. The latter, therefore, is probably $S[CMe(OH)\cdot CH\colon CHPh]_2$, and the sulphoxide is $SO[OMe(OH)\cdot CH\colon CHPh]_2$. The disulphide and the sulphide cannot be benzoylated or acetylated, but both, and also the sulphoxide, yield styryl methyl ketone-phenylhydrazone by treatment with phenylhydrazine.

[With Emil Hubert.]—*Benzylideneacetophenone hydrosulphide*, $CHPh\colon CH\cdot CPh(OH)\cdot SH$, m. p. 107°, is obtained by the action at 0° of hydrogen sulphide on an alcoholic solution of phenyl styryl ketone containing a little potassium hydroxide. It forms a S-*benzoyl* deriv-ative, $CHPh\colon CH\cdot CPh(OH)\cdot SBz$, m. p. 125°, which is not oxidised to a disulphide by iodine. *Dibenzylideneacetophenone disulphide*,

$$S_2[CPh(OH)\cdot CH\colon CHPh]_2,$$
m. p. 159°, is obtained by oxidising the preceding hydrosulphide by iodine in alcohol-chloroform solution, or by adding cold alcoholic phenyl styryl ketone to alcoholic sodium sulphide saturated with sulphur and with hydrogen sulphide.

The amorphous α- and β-duplobenzylideneacetophenone sulphides, m. p. 96° and 181° respectively, described by Fromm and Lambrecht (A., 1908, i, 989), are not pure. The pure substances are crystalline, have m. p. 109° and 186° respectively, and have the formula $C_{30}H_{26}O_2S$, not $C_{30}H_{24}OS$. The views previously advanced to explain their isomerism are withdrawn. The pure substances are obtained by the action of alcoholic ammonia on phenyl styryl ketone hydrosul-phide in chloroform, an excess of ammonia producing the β-isomeride, m. p. 186°, a little ammonia forming the α-isomeride, m. p. 109°. This method of formation, together with the fact that the two sulphides

yield hydrogen sulphide and $1:3:5$-triphenylpyrazolone by boiling with phenylhydrazine in glacial acetic acid, leads to the formula $S[CPh(OH)\cdot CH:CHPh]_2$ for the two isomerides. α-Duplobenzylideneacetophenone sulphide is converted into the β-isomeride, not by iodine as stated by Fromm and Lambrecht (*loc. cit*), but by ammonia. The stereoisomerism of the two substances is probably similar to that of dioximes, consequently *cis-*, *trans-*, and *amphi*-modifications
should exist.   This view of the stereoisomerism receives strong support by the discovery of the third modification required by the theory. α-Duplobenzylideneacetophenone sulphide, m. p. 109° (sulphone, m. p. 198°), is obtained by passing hydrogen sulphide, without cooling, into an alcoholic solution of phenyl styryl ketone containing a little potassium hydroxide.   β-Duplobenzylideneacetophenone sulphide, m. p. 186° (sulphone, m. p. 216°), is prepared by saturating an alcoholic solution of phenyl styryl ketone with ammonia and then with hydrogen sulphide.   γ *Duplobenzylideneacetophenone sulphide*, m. p. 212° (*sulphone*, $C_{30}H_{26}O_4S$, m. p. 276°), is obtained by adding an alcoholic solution of phenyl styryl ketone to alcohol saturated with anhydrous sodium sulphide and with sulphur.   C. S.

Stereoisomerism of Derivatives of Phenacyl Sulphide. EMIL FROMM and JULIUS FLASCHEN (*Annalen*, 1912, **394**, 310—324).— Phenacyl sulphide is obtained in almost quantitative yield by Tafel and Mauritz's method (A., 1891, 302) when the solution is kept at 0° during the reaction.   In addition to the diphenylhydrazone described by these authors, a *phenylhydrazone*, $C_{22}H_{20}ON_2S$, m. p. 126°, yellow needles, can be prepared.   Phenacyl sulphide in glacial acetic acid is oxidised to *diphenacyl sulphoxide*, $SO(CH_2\cdot COPh)_2$, m. p. 98°, and in benzene is oxidised by a faintly acidified solution of potassium permanganate to *diphenacylsulphone*, m. p. 120°, colourless prisms.   The sulphone yields *diphenacylsulphone dibenzylmercaptole*, $SO_2[CH_2\cdot CPh(S\cdot C_7H_7)_2]_2$, m. p. 110°, by treatment with an excess of benzyl mercaptan in glacial acetic acid saturated with hydrogen chloride, and forms only a *dimethyl* derivative, $SO_2(CHMe\cdot COPh)_2$, m. p. 178°, with methyl iodide and sodium ethoxide in alcohol.   In boiling glacial acetic acid, phenacylsulphone and the calculated quantity of phenylhydrazine yield *diphenacylsulphonediphenylhydrazone*,
$$SO_2(CH_2\cdot CPh:N\cdot NHPh)_2.$$
This crystallises from glacial acetic acid in yellow needles, m. p. 148°, and from alcohol or from benzene and petroleum in pale yellow needles, m. p. 160°.   This second modification, which can also be obtained by
the interaction of diphenacylsulphone and phenylhydrazine in alcohol containing a little sodium hydroxide, is converted into the first modification, m. p. 148°, by crystallisation from glacial acetic acid. A third *isomeride*, m. p. 170°, is obtained from diphenacylsulphone and phenylhydrazine in alcohol, *anhydrodiphenacylsulphonephenylhydrazone*,

$$C_{22}H_{18}O_2N_2S,$$
m. p. 187°, being also produced. *Diphenacylsulphonephenylhydrazone*, m. p. 193°, yellow needles, is prepared by crystallising the preceding anhydride from glacial acetic acid or by boiling equal molecular quantities of diphenacylsulphone and phenylhydrazine in the same solvent. Reasons are given for regarding this phenylhydrazone as *trans*-diphenacylsulphonephenylhydrazone and the anhydride as a derivative of the *cis*-isomeride; the diphenylhydrazones, m. p. 148°, 160°, and 170°, are regarded as having the *trans*-, *amphi*-, and *cis*-configurations respectively.

Anhydrodiphenacylsulphonedioxime,

$$\begin{matrix} CPh \cdot CH_2 \\ N\text{------}O \end{matrix} \!\!>\!\! SO \cdot CH_2 \cdot CPh \!:\! NOH,$$
m. p. 167° white needles, prepared from diphenacylsulphone and hydroxylamine hydrochloride (2 mols.) in alcohol in the presence of sodium carbonate or acetate, yields *acetyldiphenacylsulphoneoxime*, $C_{18}H_{17}O_5NS$, m. p. 110°, by boiling with acetic anhydride. cis-*Diphenacylsulphonedioxime*, m. p. 204° (*acetyl* derivative, m. p. 158°), is obtained from diphenacylsulphone and an excess of hydroxylamine hydrochloride in boiling alcohol containing a drop of hydrochloric acid. trans-*Diphenacylsulphonedioxime*, m. p. 190° (*acetyl* derivative, m. p. 146°), is obtained together with the monoxime, m. p. 173°, by heating diphenacyl sulphone with hydroxylamine hydrochloride (2 mols.) and calcium carbonate (1 mol.) in alcohol through which carbon dioxide is being passed. cis-*Diphenacylsulphoneoxime*, $C_{16}H_{15}O_4NS$, m. p. 144°, is obtained from equal molecular quantities of diphenacylsulphone and hydroxylamine hydrochloride in the presence of sodium carbonate or acetate. trans-*Diphenacylsulphoneoxime*, m. p. 173°, is obtained from equal molecular quantities of diphenacylsulphone and hydroxylamine hydrochloride in boiling alcohol in the presence of calcium carbonate. The monoximes each yield the same acetyl derivative, m. p. 110°, as that obtained from anhydrodiphenacylsulphonedioxime. The *cis*-oxime, m. p. 144°, yields anhydrodiphenacylsulphonedioxime by further treatment with hydroxylamine hydrochloride and sodium carbonate, and the *cis*-dioxime by treatment with hydroxylamine hydrochloride and calcium carbonate. The *trans*-oxime, m. p. 173°, yields only anhydrodiphenacylsulphonedioxime by treatment with hydroxylamine hydrochloride and sodium carbonate or calcium carbonate. Since the anhydrodioxime is produced from each of the monoximes, it is certainly derived from the *amphi*-dioxime. The configurations of the other substances are not established with certainty, C. S.

Transformations of Thujane. II. NICOLAI M. KISHNER (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1759—1762. Compare A., 1911, i, 71, 996).—Decomposition by means of aniline or alcoholic potassium hydroxide of the unstable bromide obtained by shaking thujane with

fuming hydrobromic acid for a comparatively short time (two to three hours) yields a mixture of two isomeric hydrocarbons, $C_{10}H_{18}$, the one with the higher boiling point predominating when alkali is employed The properties of various preparations of these hydrocarbons are as follows : (1) b. p. 160—161·5°/753 mm., D_0^{20} 0 8085 (or 0·8082), n_D 1·4490, $[a]_D$ +17 86° (or +15·59°); (2) b. p 166—168°/754 mm., D_0^{20} 0·8159 (or 0·8188), n_D 1·4538, $[a]_D$ +6·13° (or +2·8°). If the action of the hydrobromic acid on thujane is prolonged for fifteen hours, distillation of the bromide yielded with aniline gives hydrocarbons with the constants : (1) b. p. 160—162°/762 mm., D_0^{20} 0 8093, n_D 1·4494, $[a]_D$ +3·67°, (2) b. p. 167 5—170°/761 mm, D_0^{20} 0 8171, n_D 1·4555, $[a]_D$ +2·4°.

Both hydrocarbons contain the same carbon atom nucleus, since reduction of them by Sabatier's method leads to one and the same hydrocarbon, $C_{10}H_{20}$, b. p. 161—163°/753 mm. (or 759 mm.), D_0^{20} 0 7904 (or 0·7902), n_D 1·4319 (or 1·4336), $[a]_D$ −1·29° (or −1·21°)

T. H. P.

A Special Case of Racemism. MAURIZIO PADOA and G. ROTONDI (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 626—631).—The paper deals with the thermal analysis of the system formed by the two modifications (namely, the stable, m. p. 75°, and the labile, m. p. 45°) of optically active bromocamphor (*d*- or *l*-) This presents a case not considered by Roozeboom in his analysis of the criteria for the characterisation of inactive mixtures, because each enantiomorph exists in two modifications. Mixtures containing more than about 58% of *d*-bromocamphor, or more than 58% of *l*-bromocamphor, have an initial m. p., with separation of pure solvent. As the cooling is continued the composition mentioned is reached and the labile form then appears. At this point the whole mass solidifies and pure solvent separates along a curve shown until the inactive conglomerate is reached, which possesses the lowest transformation point. Below the curve just mentioned and the m.-p. curve of the labile modification, only conglomerates of the two bromocamphors are stable. Fused mixtures which contain less than 58% of *d*-bromocamphor and less than 58% of *l*-bromocamphor crystallise in the labile form, and when cooling is continued they are transformed into conglomerates. The labile forms have therefore a small area of stability, bounded by the curve of the labile modification and the curve of the separation of conglomerates already mentioned.

As regards the characterisation of the racemism, the racemic compound exists between 44° and 50·5°; below that it is split into inactive conglomerates. This is analogous to the behaviour of sodium ammonium racemate studied by van't Hoff.   R. V. S.

The Constituents of Essential Oils (The Constitution of Selinene). FRIEDRICH W. SEMMLER and FELIX RISSE (*Ber*, 1912, 45, 3725—3731. Compare this vol., i, 66).—In the former communication, the sesquiterpene, selinene, was shown to give a dihydrochloride from which a regenerated selinene with slightly higher rotation, due perhaps to a different arrangement of the unsaturated linkings, could be obtained. In order to elucidate the constitution of these isomerides, they have been oxidised with ozone.

Natural ψ-(β)-selinene on oxidation gave a very small amount of an acid, but chiefly an indifferent product which was purified by conversion into a *disemicarbazone*, $C_{18}H_{20}(N \cdot NH \cdot CO \cdot NH_2)_2$, m. p. 228°, from which the saturated *diketone*, $C_{18}H_{20}O_2$, b. p. 178—180°/11 mm., D^{20} 1·0566, n_D 1·49994, $a_D + 15°$, was recovered by means of oxalic acid. The fact that two carbon atoms have been eliminated by this process, whereas the acid resulting from the oxidation by hypobromite contains only one carbon atom less, indicates the presence in selinene of one methylene group attached directly to the ring and another in a side-chain.

Regenerated selinene, *ortho*-(a)-selinene, b. p. 128—132°/11 mm., D^{20} 0·9190, n_D 1·50920, $a_D + 61°36'$, gives much less of the diketone on treatment with ozone, the chief product being the acid, which has been characterised as *methyl selinenediketomonocarboxylate*, $C_{15}H_{24}O_4$, b. p. 185—190°/11 mm., D^{20} 1·0635, n_D 1·47889, $a_D + 4°24'$. The formation of this acid is explained by assuming that the elimination of hydrogen chloride from the dichloride has resulted in the displacement of a double bond into the ring. A consideration of other sesqui-terpenes leads to the adoption of the annexed formulæ.

Chemical Investigation of the Oil of Chenopodium. II. E. K. NELSON (*J. Amer. Chem. Soc.*, 1913, **35**, 84—90. Compare A., 1911, i, 797).—It has been found that when the glycol anhydride formed by the molecular rearrangement of ascaridole is treated with dilute sulphuric acid, ascaridole α-glycol is produced together with two other crystalline substances, one of which, termed *ascaridole β-glycol*, $C_{10}H_{18}O_3$, crystallises with $1H_2O$; the anhydrous substance has m. p. 103—105°; when this glycol is warmed with dilute sulphuric acid, thymol is produced. The other *substance*, termed the "erythrite," $C_{10}H_{20}O_4$, also crystallises with $1H_2O$, and when anhydrous has m. p. 128—130°; it is decomposed by boiling dilute sulphuric acid with formation of a *ketone*, with a strong menthone-like odour, and a

phenolic substance, m. p. 80—81°; the *semicarbazone* of the ketone has m. p. 182—184°. On oxidising the "erythrite" with alkaline potassium permanganate, an *acid*, $C_{10}H_{18}O_6$, m. p. 190—191°, is produced, which forms rhombic prisms; when this acid is heated at 210°, it is converted into its anhydride, and on further heating yields ascaridic anhydride, m. p. 70—71°. If the acid $C_{10}H_{18}O_6$ is oxidised with potassium permanganate in presence of sulphuric acid, it yields β-methylheptane-$\gamma\zeta$-dione, and it is therefore probable that it is a modification of $\alpha\alpha$-dihydroxy-α-methyl-α-*iso*propyladipic acid. The "erythrite" therefore probably has the structure

$$OH \cdot CMe \overset{CH_2 \underline{\hspace{1cm}} CH_2}{\underset{CH(OH) \cdot CH(OH)}{\big<}} C(C_3H_7) \cdot OH.$$
The acid, $C_{10}H_{16}O_5$, obtained by the oxidation of the α-glycol, is converted by further oxidation into β-methylheptane-$\gamma\zeta$-dione. When the glycol anhydride is boiled with a saturated solution of oxalic acid, a small quantity of the phenolic substance, m. p. 80—81°, is produced, which is formed on boiling the "erythrite" with dilute sulphuric acid and is also obtained by treating the α-glycol with strong dehydrating agents. On heating the glycol anhydride with benzoic anhydride at 150°, an ester of carvacrol is produced.

From the results of this work, it is considered that the α-glycol has the constitution $CMe \overset{CH_2 \underline{\hspace{1cm}} CH_2}{\underset{CH(OH) \cdot CH(OH)}{\big<}} \overset{\big\backslash}{\underset{\big/}{O}} C \cdot C_3H_7$, and that the acid obtained by its oxidation has the structure of $\alpha\delta$-cineolic acid, $CO_2H \cdot CMe \cdot CH_2 \cdot CH_2 \cdot C(C_3H_7) \cdot CO_2H$.   E. G.

Action of Gaseous Oxygen on Caoutchouc STANLEY J. PEACHEY (*J. Soc. Chem. Ind.*, 1912, 31, 1103—1104).—When purified caoutchouc, in the form of a thin film, is exposed to an atmosphere of oxygen at a temperature of 85°, oxidation commences after a few hours' heating, and then proceeds rapidly to completion. Results of experiments with Ceylon caoutchouc show that, under these conditions, each $C_{10}H_{16}$ unit of the molecule combines with 4 atoms of oxygen. This result is not in agreement with that obtained by Herbst (A., 1906, 1, 196), and it may be assumed that the reaction which takes place when caoutchouc in benzene solution is oxidised by air (as in Herbst's experiments) differs from that which occurs when caoutchouc itself is oxidised by pure oxygen. The oxidation most probably results in the formation of additive products.   W. P. S.

The Nitrogenous Constituent of Para Caoutchouc and Its Bearing on the Nature of Synthetic Caoutchouc. CLAYTON BEADLE and HENRY P. STEVENS (*J. Soc. Chem. Ind.*, 1912, 31, 1099—1101. Compare A., 1912, i, 789).—It is shown that the removal of insoluble (nitrogenous) constituents from caoutchouc results in deterioration of the latter, although it is open to question how far the quality of caoutchouc is improved by the presence of more than a certain proportion of insoluble matter. In the vulcanisation process the insoluble matter appears to play the part of a sulphur carrier.

The authors have also made experiments on the influence of the resinous constituents on the vulcanising properties of caoutchouc, and find that the removal of the resins results in a marked deterioration of the quality of the caoutchouc. The absence of nitrogenous substances and resins in synthetic caoutchouc should make the latter inferior to natural rubber. W. P. S.

Chemistry of Caoutchouc. VI. Theory of Vulcanisation. IV. DAVID SPENCER and C. A. WARD (*Zeitsch. Chem. Ind. Kolloide*, 1912, 11, 274—280. Compare A., 1912, i, 706).—Experiments have been made to ascertain whether the so-called "depolymerisation" of caoutchouc, which is brought about by mechanical or thermal treatment, is accompanied by a change in the rate at which it reacts with sulphur in the process of vulcanisation. For this purpose comparative measurements were made with two exactly similar mixtures of 100 parts of caoutchouc and 10 parts of sulphur. In the one case the caoutchouc was kneaded for thirty minutes at a moderate temperature, the sulphur being then added, and the mixing effected by a further kneading for ten minutes. In the second case, the treatment was similar, except that the caoutchouc was subjected to the mechanical treatment for ninety minutes at a much higher temperature.

From the observations made on the rate of vulcanisation at 135°, it appears that there is no appreciable difference between the two samples, and the authors draw the conclusion that "depolymerisation" has no influence whatever on the chemical result of the vulcanisation process. The conclusions arrived at by Axelrod (*Gummi Zeit.*, 1909, 24, 352) are therefore not confirmed by these experiments. H. M. D.

The Action of Chloroacetyl Chloride on Ethyl Malonate; Iminotetronic Acid. ERICH BENARY (*Ber.*, 1912, 45, 3682—3686). —As the substance described as the ester-amide of tetramic acid (Benary, A., 1911, i, 672) is in reality ethyl iminotetron-α-carboxylate (Anschütz, A., 1912, i, 836), the compound $C_9H_{12}O_5$, from which it is obtained by the action of ammonia, is presumably ethyl *iso*tetron-α-carboxylate; this view is supported by the action of organic bases which give compounds similar to that produced by ammonia; these compounds are probably ketonic, but do not yield phenylhydrazones (compare Wolff, A., 1900, i, 582); they frequently yield salts, however, derived from the enolic structure.

Ethyl phenyliminotetron-α-carboxylate, $\begin{matrix} CH_2—CO \\ O\cdot C(:NPh) \end{matrix}\!\!>\!CH\cdot CO_2Et$, obtained by the interaction of equivalent quantities of ethyl *iso*tetron-α-carboxylate and aniline, crystallises in needles, m. p. 116—117°; it exhibits both acidic and basic properties.

Ethyl phenylhydrazinotetron-α-carboxylate (already described) yields a *potassium* salt.

Ethyl piperidinoisotetron-α-carboxylate, $\begin{matrix} CH_2—CO \\ O\cdot C(C_5NH_{10}) \end{matrix}\!\!>\!C\cdot CO_2Et$, m. p. 107.—108°, from equal weights of piperidine and ethyl *iso*tetron-

α-carboxylate, as might be expected from the structure, has no acidic properties.

When iminotetronic acid in benzene solution is treated with rather more than an equimolecular quantity of bromine, *bromoiminotetronic acid*, $\begin{smallmatrix} CH_2 \cdot C(OH) \\ O—C(:NH) \end{smallmatrix}\!\!>\!CBr$, needles, m. p. 182°, is obtained; it gives a red coloration with ferric chloride.

On adding ice to the reaction mixture from iminotetronic acid and nitric acid, aci-*nitroiminotetronic acid*, $\begin{smallmatrix} CH_2—CO \\ O \cdot C(:NH) \end{smallmatrix}\!\!>\!C:NO_2H$, is precipitated, leaflets, m. p. 255—258° (decomp.); it is a strongly acidic substance, which gives a *phenylhydrazone*, yellow tablets, m. p. 211—212°.

The conclusion is drawn that the action of chloroacetyl chloride on ethyl sodiomalonate consists of two concurrent processes, one of which produces unstable ethyl chloroacetylmalonate, which undergoes spontaneous change into ethyl tetron-α-carboxylate, whilst the other process involves the enolic form of ethyl sodiomalonate, which reacts with the acid chloride producing ethyl *iso*tetron-α-carboxylate.   D. F. T.

Hydroxymethylfurfuraldehyde. FRANCESCO ANGELICO and A. COPPOLA (*Gazzetta*, 1912, **42**, ii, 583—589).—The authors confirm the formula for this substance given by Fenton and Gostling (T., 1889, **75**, 423), and by the application of the Angeli-Rimini reaction they have prepared from it *α-hydroxymethylfuranhydroxamic acid*, $C_6H_7O_4N$, which crystallises in pink, lustrous, soapy scales, m. p. 139°, the free acid being prepared from the *copper salt*, $(C_6H_6O_4N)_2Cu,H_2O$. When the acid is hydrolysed with 25% sulphuric acid, it yields hydroxylamine and hydroxypyromucic acid (m. p. 165°).
     R. V. S.

Constitution of Bergapten. HERMANN THOMS and E. BAETCKE (*Ber.*, 1912, **45**, 3705—3712).—Bergapten, which Pomeranz showed to be a coumarin-coumarone derivative of phloroglucinol (A., 1892, 71; 1893, 342), was found to occur in certain fruits accompanied by an isomeride, xanthotoxin (A., 1912, i, 40), to which the formula (I) was assigned. Bergapten has now been converted into an amine, and this into a quinone containing no methoxy-group, from which the conclusion is drawn that the methoxy-group is *para* to the unsubstituted carbon atom, and that the substance has the constitution (II).

I. $CH\!\!<\!\!\begin{smallmatrix} O \\ CH \end{smallmatrix}\!\!>\!\!\begin{smallmatrix} OMe \\ O—CO \\ CH:CH \end{smallmatrix}$ II. $CH\!\!<\!\!\begin{smallmatrix} CH \\ O \end{smallmatrix}\!\!>\!\!\begin{smallmatrix} OMe \\ CH:CH \\ O—CO \end{smallmatrix}$

This is confirmed by the fact that xanthotoxin yields the same quinone.

Aminobergapten, $C_{12}H_7O_4 \cdot NH_2$, is obtained by the reduction of the nitro-derivative (Pomeranz, *loc. cit.*) with tin and hydrochloric acid, in slender, pale yellowish-green needles, m. p. 198°, and yields an *acetyl* compound, m. p. 208°. When oxidised with sodium dichromate the

methoxy-group is replaced, and the golden-yellow *quinone*, $C_{11}H_4O_5$, m. p. 248—250°, is formed. *Aminoxanthotoxin* is prepared in the same way, and is similar in appearance to its isomeride; it melts, however, at 236°, is more easily acetylated, yielding an *acetyl* compound, m. p. 246—247°, and is much less soluble in cold sulphuric acid, but it yields the same quinone.

The *quinol*, $C_{11}H_4O_3(OH)_2$, crystallises with $2H_2O$ in light green needles, which lose water at 110°, and yield a *diacetyl* compound, m. p. 208—209°, and a *diphenylurethane* derivative, $C_{11}H_4O_3(O \cdot CO \cdot NPh_2)_2$, m. p. 229—230°.

<div align="right">J. C. W.</div>

Action of Hydrogen Peroxide on Hydroxythionaphthen, Hydroxythionaphthen Carboxylic Acid, and "Thioindigo."

MAURICE LANFRY (*Compt. rend.*, 1912, 155, 1517—1519. Compare A., 1912, i, 293).—Hydroxythionaphthen in alkaline solution gives a blue precipitate on the addition of hydrogen peroxide, leaving a brown liquid, from which only gummy substances could be extracted. The blue precipitate on solution in water and addition of strong acid gives a red, flocculent precipitate, which resembles "thioindigo" in all its properties. The addition of hydrogen peroxide to a boiling solution of hydroxythionaphthen in acetic acid gives a red precipitate of "thioindigo," which slowly dissolves and the solution becomes colourless. Extraction with benzene separates out 3-*hydroxy*-1-*dioxythionaphthen* (annexed constitution), m. p. 139°, which in its chemical properties closely resembles the hydroxythionaphthen from which it is prepared.

The effect of hydrogen peroxide on the sodium salt of hydroxythionaphthencarboxylic acid is to destroy its phenolic character with the formation of a small quantity of "thioindigo." The major part of the salt is resinified.

In the presence of hydrogen peroxide, finely divided "thioindigo" slowly dissolves in acetic acid to a red solution, which gradually becomes decolorised. The only products of extraction were gummy substances.

<div align="right">W. G.</div>

"Bisphenylthiophenindigo" [5 : 5′- Diphenyl-$\Delta^{2,2'}$-bisthiophen-3-one]. PAUL FRIEDLAENDER and ST KIELBASINSKI (*Ber.*, 1912, 45, 3389—3396).—Although *m*-hydroxydiphenyl shows no tendency to pass over into an ortho-quinonoid compound, the analogous 3-hydroxy-5-phenylthiophen behaves entirely differently, readily forming "*bisphenylthiophenindigo*,"

The dye is prepared by the following series of operations. On heating ethyl cinnamate with sulphur, a disulphide, thiobenzoylthioacetic acid, $S\diagdown\substack{S—CO \\ CPh:CH}$ (Baumann and Fromm, A., 1897, i, 191), is formed. The ring is opened by sodium sulphide, and by the action of chloroacetic acid a compound,

$$CO_2H \cdot CH_2 \cdot S \cdot CPh:CH \cdot CO \cdot S \cdot CH_2 \cdot CO_2H,$$

is formed, which when boiled with acetic anhydride is converted into acetoxyphenylthiophen, $S<^{CH-C \cdot O \cdot CO \cdot CH_3}_{CPh:CH}$. On hydrolysis, 4-hydroxy-2-phenylthiophen is obtained.

This condenses with aromatic aldehydes or with isatin to dyes, forms a quinoneoxime with nitrous acid, and is converted by alkaline or acid oxidising agents into " bisphenylthiophenindigo."

The *disulphide* crystallises in broad needles, m. p. 156°.

4-Hydroxy-2-phenylthiophen separates in slender needles, m. p. 78°, the *acetyl* derivative forms broad, colourless, compact platelets, m. p. 75°.

The *quinone oxime*, $S<^{CPh \!=\!=\! CH}_{C(:N \cdot OH) \cdot CO}$, prepared by interaction with sodium nitrite, forms broad faint. brownish-yellow needles, m. p. 216°.

On bromination, a *product*, $CPh<^{CBr \cdot CO}_{S-CBr_2}$, is obtained, crystallising in brownish-yellow plates, m. p. 134°. It does not react simply with aniline : on warming with sodium acetate, slender, red needles or ruby-red prisms of a brominated diphenylthiophenindigo are obtained.

4-Hydroxy-2-phenylthiophen reacts with piperonal, the *condensation* product crystallising in long, yellow needles, m. p. 196°.

"*Bis-5-phenyl-2-thiophenindigo*" [5 . 5'-diphenyl-Δ²⁻²'-bisthiophen 3-one] separates in brownish-red, lustrous needles, m. p. 280°.

" *5-Phenyl-2-thiophen-3 indoleindigo* " [5-phenyl-2-(3'-indoxyl)-thiophen-3-one], produced on condensation with isatin, crystallises in sealing wax-red needles, m. p. 281°.

" *5-Phenyl-2-thiophen-2-indoleindigo* " [5-phenyl-2-(2'-indoxyl)-thiophen-3-one], $^{CH \cdot CO}_{CPh \cdot S}>C:C<^{CO}_{NH}>C_6H_4$, obtained on boiling isatin-anilide with phenylhydroxythiophen in acetic anhydride, crystallises in slender, dark violet needles.   E. F. A.

Methylation of Histidine, Arginine, and Lysine. I. R. ENGELAND and FRIEDRICH KUTSCHER (*Zeitsch. Biol* , 1912, 59, 415—419). —On methylation of histidine monochloride with methyl sulphate and barium hydroxide, *pentamethylhistidine* is obtained. The *aurichloride* crystallises in large, lustrous needles, the *chloride* is an oil, and the free base decomposes rapidly. Small quantities of the crystalline *aurichloride* of tetramethylhistidine are obtained at the same time.

Under similar conditions, arginine yields a *tetramethyl* derivative, the *aurichloride* forms short, stout needles, m. p. 173—175°. Three of the methyl groups are attached to nitrogen in the side-chain, one only to nitrogen in the guanidine complex.

Lysine yields a compound, probably the *ethyl* ester of *hexamethyllysine*, which gives an *aurichloride*, m. p. 208°, corresponding with the formula $C_{14}H_{34}O_3N_2,Au_2Cl_8$.   E. F. A.

Strychnos Alkaloids. XVI. **Dihydrobrucinoic Acid and** *iso*Brucinolone. HERMANN LEUCHS and GEORGE PEIRCE (*Ber.*, 1912, 45, 3412—3420).—Dihydrobrucinonic acid, which contains an alcoholic

hydroxyl (compare A.. 1212, i, 210), forms an acetyl derivative when acted on by acetic anhydride and sodium acetate. More vigorous action produces a neutral compound containing two further acetyl residues less a molecule of water. Dihydrobrucinonic acid does not react with nascent hydrogen or with hydroxylamine. It is broken down by sodium hydroxide into glycollic acid and *iso*brucinolone, $C_{21}H_{22}O_7N_2$. The latter forms an acetyl derivative, and on treatment with concentrated hydrogen chloride gives iso*brucinolone hydrate*. At higher temperatures this is reconverted into *iso*brucinolone (compare Leuchs and Brewster, A., 1912, i, 210). With concentrated nitric acid a nitro-derivative, $C_{19}H_{15}O_7N_3$, is obtained; the change involves the formation of a quinone and the subsequent nitration of this. With sulphurous acid a paler reduction compound is obtained from the quinone.

Acetyldihydrobrucinonic acid forms colourless, four-sided prisms, m. p. 235—238°. The neutral product, $C_{27}H_{28}O_9N_2$ or $C_{29}H_{30}O_{10}N_2$, crystallises in colourless, chisel-shaped prisms, m. p. 280—282°, after becoming yellow at 260°.

By the action of acetic anhydride on brucinonic acid, a compound,

$$(C_{18}H_{14}O_4N)_x$$

is obtained, crystallising in long, matted, lustrous needles, m. p. 125—127°.

*Acetyliso*brucinolone forms large, colourless platelets, m. p. 281—283° (decomp.).

iso*Brucinolone hydrate* separates in four-sided prisms, which froth at 205—208°, become solid again, turn brown at 290°, m. p. 310—315° (decomp.).

The *hydrochloride* forms four-sided platelets; the *sulphate* consists of massive prisms, which become brown at 235°, decomp. 238°.

*Nitrobisapomethyldihydroiso*brucinolone crystallises in flat, orange-yellow needles, which become brown at 250°, and completely charred at 340°.

*Nitrobisapomethyliso*brucinolone gives massive, reddish-yellow prisms, which become brown at 240°.

Nitrobisapomethylbrucinolone crystallises in small, yellow octahedra, dissolving in concentrated sulphuric acid with a yellow coloration and in concentrated sodium hydroxide with a violet coloration.

E. F. A.

Strychnos Alkaloids. XVII. Isolation of the Hydrate of a Fourth Strychninesulphonic Acid. HERMANN LEUCHS and JOHANNES WUTKE (*Ber*, 1912, 45, 3686—3691).—Analogous to the fourth brucinesulphonic acid (Leuchs and Geiger, A., 1911, i, 1018), a fourth strychninesulphonic acid (compare Leuchs and Schneider, A., 1909, i, 671) has been obtained as a very stable hydrate, which retains the additional water very tenaciously.

The solution of the reaction product obtained as described earlier (Leuchs and Schneider, *loc. cit.*), after crystallisation of strychnine-sulphonic acids I and II, and subsequent concentration under reduced pressure, deposits a mixture of the acids I, II, and III with the above-mentioned hydrate, which last can be separated in the free

state and also as a compound with strychninesulphonic acid III; the total yield of hydrate in the two forms amounts to approximately 3%.

Strychninesulphonic acid IV *hydrate*, $C_{21}H_{24}O_6N_2S,2H_2O$, stout prisms or rhombohedra, m. p. 275° (decomp.), $[a]_D^{20} + 18\cdot3°$, could not be dehydrated beyond $C_{21}H_{24}O_6N_2S$, even at 135° in a vacuum over phosphoric oxide. The *double* compound with strychninesulphonic acid III, $C_{21}H_{22}O_5N_2S,C_{21}H_{24}O_6N_2S$, slender prisms or needles, m. p. 250° (decomp.), $[a]_D^{20} + 101°$, can also be obtained by mixing solutions of the hydrate and excess of the acid III; in the absence of excess of strychninesulphonic acid III, the compound is resolved by hot water into its constituents.   D. F. T.

Synthesis of **Hæmopyrrole-*b***. OSKAR PILOTY and A. BLOMER (*Ber.*, 1912, **45**, 3749—3753).—Ethyl acetylpyruvate condenses with aminobutanone or with aminoacetone to form pyrrole derivatives. In the former case, 4-acetyl-2 : 3-dimethylpyrrole-5-carboxylic acid,

$$NH\!<\!\genfrac{}{}{0pt}{}{C(CO_2H)\!:\!C\cdot COMe}{CMe\!=\!=\!CMe}\;,$$
is obtained, which on heating at 215° is converted into 4-*acetyl*-2 : 3-*dimethylpyrrole*, $NH\!<\!\genfrac{}{}{0pt}{}{CH\!=\!C\cdot COMe}{CMe\!:\!CMe}$. When this is treated with hydrazine and sodium ethoxide, 2 : 3-dimethyl-4-ethylpyrrole (hæmo-pyrrole-*b*), $NH\!<\!\genfrac{}{}{0pt}{}{CH\!=\!CEt}{CMe\!:\!CMe}$, is formed.

With aminoacetone the product is 4-*acetyl-3-methylpyrrole-5-carb-oxylic acid*, $NH\!<\!\genfrac{}{}{0pt}{}{C(CO_2H)\!:\!C\cdot COMe}{CH\!=\!=\!CMe}$. This has m. p. 200°. During the reaction an isomeric by-product, m. p. 250° (decomp.), is also formed.

4-*Acetyl*-2 : 3-*dimethylpyrrole-5-carboxylic acid* crystallises in colour-less, prismatic rods, m. p. 204° (decomp.).

4-*Acetyl*-2 : 3-*dimethylpyrrole* separates in short, colourless, prismatic platelets with sharp edges, m. p. 137°. The synthetic hæmopyrrole-*b* is identical with the natural compound.   E. F. A.

Cyclic Imines. VII. Ahrens' So-called γ-Picoline. JULIUS VON BRAUN and A. SCHMATLOCH (*Ber.*, 1912, **45**, 3649—3652).—The method described by Ahrens for the separation of pure 4-methylpyridine (γ-picoline) by precipitation with mercuric chloride (A., 1905, i, 232) is found to yield a mixture instead of a pure product.

Successive reduction and benzoylation of 4-methylpyridine, prepared by Ahrens' method, produced a *benzoyl* derivative, $C_6H_{12}NBz$, b. p 189—190°/17 mm., which on distillation with phosphorus pentabromide (compare von Braun and Sobecki, A., 1911, i, 413) formed a product which could be separated into two fractions by distillation. The smaller and less volatile portion, b. p. 150°/19 mm., $D_4^{20} 1\cdot9305$, was probably *aβε-tribromo-β-methylpentane*, and gave an unsaturated organo magnesium compound which absorbed carbon dioxide with the formation of *δ-methylene-n-hexoic acid*, $CO_2H\cdot[CH_2]_3\cdot CMe\!:\!CH_2$, b. p. 218—221°, $D_4^{20} 0\cdot9406$, $n_D 1\cdot4442$; the formation of this series of compounds is attributed to the presence of 3-methylpyridine in the

original base. The more volatile fraction, $C_6H_{12}Br_2$, b. p. 115—120°/ 19 mm., D_4^{20} 1·608, on treatment with potassium cyanide yielded a dinitrile, $C_6H_{12}(CN)_2$, b. p. 171—174°/10 mm., which was hydrolysable, apparently to a mixture of β- and γ-methylpimelic acids. Neither fraction therefore was of pure 4-methylpyridine. D. F. T.

The Action of Hydroxylamine and Phenylhydrazine on Benzoyldehydracetic Acid. A Correction. Joh. Schöttle (*Ber.*, 1912, **45**, 3779. Compare A., 1912, i, 915).—Reaction between free hydroxylamine and benzoyldehydracetic acid was effected by mixing hydroxylamine sulphate with the theoretical quantity of alcoholic potassium hydroxide, filtering the precipitated potassium sulphate, and adding the phenyl-lactam of benzoyldehydracetic acid to the filtrate.

E. F. A.

Cyclic Imines. VI. Ring Homologues of Tetrahydroquinoline. Julius von Braun and B. Bartsch (*Ber.*, 1912, **45**, 3376—3389).—The tendency to form seven-membered rings such as hexamethyleneimine is very much increased when two of the carbon atoms are members of a benzene nucleus; thus o-δ-chlorobutylaniline, on elimination of hydrogen chloride, readily forms *tetrahydrohomoquinoline*, $C_6H_4{<}{CH_2 \cdot CH_2 \atop NH-CH_2}{>}CH_2$. The constitution of the quinoline is established by the fact that when the ring is opened by the action of phosphorus pentachloride, δ-chloro-o-benzoylaminobutylbenzene, $COPh \cdot NH \cdot C_6H_4 \cdot [CH_2]_4Cl$, is formed, which is in turn convertible into the already known δ-o-benzoylaminophenylvaleric acid.

Homotetrahydroquinoline resembles the isomeric 2-methyltetrahydroquinoline and the lower ring homologues in its stability towards hydrolytic and reducing reagents, and also towards oxidation; it is hardly altered by distillation with silver sulphate.

The quinoline could not be prepared by other methods, such as the distillation of δ-o-diaminobutylbenzene hydrochloride or by the interaction of γ-phenylpropylamine with formaldehyde.

o-*Amino-δ-hydroxybutylbenzene*, $NH_2 \cdot C_6H_4 \cdot [CH_2]_4 \cdot OH$, prepared by the reduction of the ester, $NH_2 \cdot C_6H_4 \cdot [CH_2]_3 \cdot CO_2Et$, by means of sodium and alcohol, is a viscid, almost odourless oil, b. p. 180—183°/12 mm. The *dibenzoyl* compound crystallises in snow-white platelets which sinter at 127°, m. p. 130°; the *platinichloride* forms dark red platelets, which blacken at 168°, m. p. 175°; the *picrate* separates in green leaflets, m. p. 179°.

o-*Amino-δ-chlorobutylbenzene* was not obtained pure; the *platinichloride* crystallises in pale yellow platelets, m. p. 182—183°.

Tetrahydrohomoquinoline is an almost colourless oil, b. p. 131—133°/ 16 mm., 253—255°/760 mm., D_4^{20} 1·0325, solidifying to colourless crystals, m. p. 32°. The *hydrochloride* has m. p. 186°; the pale yellow, granular crystals of the *platinichloride* blacken at 192°, m. p. 194°; the *picrate* crystallises in yellowish-red needles, m. p. 179°; the *benzoyl* derivative has m. p. 96°, whilst the *benzenesulphonyl* compound has m. p. 109°.

The *platinichloride* of the *dimethyl* derivative, $C_{10}H_{12}NMe_2PtCl_6$, produced on long heating with methyl iodide, has m. p. 197°.

When heated with phosphorus pentachloride at 150°, tetrahydro-homoquinoline yields δ-*chloro*-o-*benzoylaminobutylbenzene*, which crystallises in lustrous, silvery platelets, m. p. 117°. The corresponding iodide when decomposed with potassium cyanide yields δ-*benzoyl-aminophenylvaleronitrile*, $C_6H_5\cdot CO\cdot NH\cdot C_6H_4\cdot [CH_2]_4\cdot CN$, m. p. 114°, from which the corresponding acid (A., 1907, i, 524) is obtained on hydrolysis.

δ-o-*Diaminobutylbenzene*, prepared by reducing the nitrile of o-benzoylaminophenylbutyric acid, forms a colourless oil of strongly basic odour, b. p. 172°/14 mm.

o-γ-*Chloropropylbenzonitrile* is a pale yellow oil, volatile in steam, b. p. 153°/19 mm. On hydrolysis, o-γ-*chloropropylbenzoic acid*,

$$CO_2H\cdot C_6H_4\cdot [CH_2]_3\cdot Cl,$$
is obtained, m. p. 79°.

The nitrile condenses with sodium phenoxide to o-γ-*phenoxypropyl-benzonitrile*, $CN\cdot C_6H_4\cdot [CH_2]_3\cdot OPh$, a pale yellow oil, b. p. 210°/23 mm. The corresponding o-γ-*phenoxypropylbenzoic acid* has m. p. 120°.   E. F. A.

Thiazoles. REINHOLD VON WALTHER and H. ROCH (*J. pr. Chem.*, 1913, [ii], 87, 27—66).—Although the condensation of thiocarbamide with ω-bromoacetophenone and other halogeno-ketones of the type $CHXR\cdot COR$ may give rise to either aminothiazoles (formula II below, R' and R" = H) or iminothiazolines (IV or V, R',R" = H), the work of Traumann (A., 1889, 414) and others has shown that only amino-thiazoles are produced. s-Disubstituted thiocarbamides always yield iminothiazolines, whilst the as-disubstituted derivatives give rise to aminothiazoles.
With respect to the mechanism of the condensation, the authors suggest that the first stage consists in the addition of the halogeno-ketone to the sulphur atom of the thiocarbamide, and that the removal of hydrogen haloid and water from the intermediate compound thus produced is preceded by the formation of an internal salt, derived from the enolic form, the constitution of this salt being determined by the relative basicity of the amino-residues of the thiocarbamide ; thus, in the condensation of as-disubstituted thiocarbamides,

$$NR'R''\cdot CS\cdot NH_2,$$
with ω-bromoacetophenone, the compound
$$NR'R''\cdot C(NH_2){:}SBr\cdot CH_2\cdot COPh$$
is first produced, which is transformed successively into the enolic salt I and aminothiazole II if NHR'R" is more feebly basic than NH_3 :

I. $\begin{array}{c} NR'R''\cdot C-NH_2-O \\ SBr\cdot CH{:}CPh \end{array}$ →   II. $\begin{array}{c} NR'R''\cdot C{=\!=}N \\ S\cdot CH{:}CPh \end{array}$ + H_2O + H.Br.

On the other hand, if NHR'R" is a stronger base than NH_3, the compound III is formed as an intermediate product, which decomposes

into a secondary amine and thiocyanoacetophenone as shown in the following scheme :

III. $\begin{matrix} \text{NHR'R''} & \text{—C·NH}_2 \\ \text{O·CPh:CH·S} & \text{Br} \end{matrix} \longrightarrow \text{HBr} + \text{H}_2\text{O} +$

$\begin{matrix} \text{NR'R''} & \text{—CN} \\ \text{CPh:CH·S} & \end{matrix} \xrightarrow{\text{H}_2\text{O}} \text{NHR'R''} + \text{OH·CPh:CH·SCN}.$

An explanation is thus afforded of the behaviour of *as*-dimethylthiocarbamide, which, with ω-bromoacetophenone, does not form an aminothiazole, but undergoes decomposition into dimethylamine and thiocyanoacetophenone (Spica and Carrara, A., 1892, 215).

s-Disubstituted thiocarbamides, NHR'·CO·NHR'', in which the amino-residues are of approximately equal basicity, may give rise to two isomeric iminothiazolines :

IV. $\begin{matrix} \text{CPh·NR''} \\ \text{CH——S} \end{matrix}{>}\text{C:NR'}$ V. $\begin{matrix} \text{CPh·NR'} \\ \text{CH——S} \end{matrix}{>}\text{C:NR''} ;$

the formation of isomerides of this kind has been observed by Stenz (*Diss.*, Dresden, 1899) and Wünsche (*ibid.*, 1901). When the basicity of one of the amino-groups is much greater than that of the other, only one isomeride will be formed ; thus, both *s-p*-tolylbenzylthiocarbamide and *s-p*-tolylmethylthiocarbamide condense with ω-bromoacetophenone to form only one iminothiazoline (formula V, where R''=*p*-C₆H₄Me, and R'=·CH₂Ph or Me). The constitution of the iminothiazolines derived from *s*-disubstituted thiocarbamides is readily determined (1) by heating with carbon disulphide, which leads to the removal of the imino-group as the corresponding thiocarbimide, or (2) by hydrolysis with hydrochloric acid, the imino-group, in this case, being removed in the form of a primary amine.

With respect to the thiazoles derived from mono-substituted thiocarbamides, the authors point out that no definite proof of their constitution has hitherto been brought forward. Although the work of Traumann (*loc. cit.*) appears to indicate that the thiazole obtained from methylthiocarbamide and ω-bromoacetophenone is probably a 2-methylimino-4-phenylthiazoline, the observations described in the present paper prove conclusively that the thiazole derived from *p*-tolylthiocarbamide has the constitution of an aminothiazole.

2-p-Toluidino-4-phenylthiazole, $\begin{matrix} \text{CPh·N} \\ \text{CH—S} \end{matrix}{>}\text{C·NH·C}_6\text{H}_4\text{Me}$, is obtained

in the form of its *hydrobromide*, slender needles, m. p. 205° (decomp.), by heating *p*-tolylthiocarbamide with ω-bromoacetophenone in alcoholic solution, the free base being liberated from the hydrobromide by warming with pyridine. It crystallises in leaflets, m. p. 123°, and forms a *hydrochloride*, which melts and becomes green at 212°, a *sulphate*, m. p. 152°, an *acetate*, m. p. 85°, and *thiocyanate*, m. p. 125°, all of which crystallise in colourless needles ; the *platinichloride* forms orange leaflets, m. p. 230°, the *picrate*, yellow needles, m. p. 185°. It reacts with phenylcarbimide in ethereal solution to form the *carbamide*, $\begin{matrix} \text{CPh·N} \\ \text{CH—S} \end{matrix}{>}\text{C·N(C}_6\text{H}_4\text{Me)·CO·NHPh}$, crystallising in lustrous leaflets,

m. p. 196·5°. Towards both oxidising and reducing agents the thiazole is remarkably stable, but is decomposed by hydrochloric acid at 225—250° into acetophenone, p-toluidine, and ammonia; when heated with carbon disulphide at 250°, it forms p-tolylthiocarbimide.

The *acetyl* derivative, $C_{18}H_{16}ON_2S$, forms colourless prisms, m. p. 124·5°; the *benzoyl* derivative, prepared by the pyridine method in benzene solution, crystallises in hard prisms, m. p. 207°.

With the object of synthesising the above acyl derivatives, the authors have endeavoured to condense ω-bromoacetophenone with *s*- and *as*-acetyl-p-tolylthiocarbamide and *s*-benzoyl-p-tolylthiocarbamide in alcoholic solution, but find that no condensation occurs. It would thus appear that acylthiocarbamides are incapable of undergoing the thiazole condensation.

2-p-Toluidino-4-phenylthiazole combines with 1-chloro-2:4:6-trinitrobenzene in hot alcoholic solution to form an unstable, additive *compound*, $C_{22}H_{16}O_6N_5SCl$, which crystallises in red needles, m. p. about 90°, and is resolved by acids or alkalis into its components; the additive *compound* with 1-chloro-2:4-dinitrobenzene forms stout, dark red crystals, m. p. about 60°.

as-p-*Tolylbenzylthiocarbamide*, $C_6H_4Me·N(CH_2Ph)·CS·NH_2$, obtained by heating N-benzyl-p-toluidine hydrochloride with ammonium thiocyanate and water, crystallises in colourless needles, m. p. 155·5°, and is converted by the action of ω-bromoacetophenone in warm alcoholic solution into 2-p-*tolylbenzylamino-4-phenylthiazole*,

$$\begin{array}{c} CPh·N \\ \| \quad \quad \rangle C·N(C_6H_4Me)·CH_2Ph, \\ CH—S \end{array}$$
which forms large prisms, m. p. 125°, and yields a *hydrochloride*, a *picrate*, m. p. 155°, and a *platinichloride*, m. p. 225° (decomp.).

2-p-*Tolylimino-4-phenyl-3-benzylthiazoline*,

$$\begin{array}{c} C_6H_4Me·N:C——N·CH_2Ph \\ S·CH:CPh \end{array}$$
prepared from *s*-p-tolylbenzylthiocarbamide and ω-bromoacetophenone, forms colourless needles, m. p. 152°; the *hydrochloride*, *platinichloride*, m. p. 233° (decomp.), and *picrate*, m. p. 155°, are described. That the compound has the above constitution, and not that of the isomeric 2-benzylimino-4-phenyl-3-p-tolylthiazoline, has been established by its behaviour towards carbon disulphide, which at 200° leads to the removal of the p-tolylimino-group as p-tolylthiocarbimide and the formation of 2-*thion-4-phenyl-3-benzylthiazoline*, $\begin{array}{c} S——CS \\ \quad \quad \rangle N·CH_2Ph, \\ CH:CPh \end{array}$ which crystallises in pale yellow needles, m. p. 101°.

When heated with benzyl chloride for eight hours at 175°, 2-p-toluidino-4-phenylthiazole yields 2-p-*tolylbenzylamino-4-phenyl-5-benzylthiazole*, $\begin{array}{c} CPh——N \\ \| \quad \quad \rangle C·N(C_6H_4Me)·CH_2Ph. \\ C(CH_2Ph)·S \end{array}$ This forms needles, m. p. 125°, and is accompanied by 2-p-*toluidino-4-phenyl-5-benzylthiazole*, $\begin{array}{c} CPh——N \\ \| \quad \quad \rangle C·NH·C_6H_4Me, \\ C(CH_2Ph)·S \end{array}$ which crystallises in needles, m. p. 174°, and yields a *platinichloride*, m. p. 203° (decomp.), and a *picrate*, m. p. 151°.

That the introduction of the benzyl group has taken place in the thiazole ring and not in the *p*-toluidino-residue has been proved in the case of the last-mentioned thiazole by the formation of an *acetyl* derivative, $C_{25}H_{22}ON_2S$, m. p. 144°, and also by the removal of the *p*-tolylimino-group as *p*-tolylthiocarbimide when the thiazole is heated with carbon disulphide.

2-p-*Tolylimino-4-phenyl-3-methylthiazoline*,

$$\begin{array}{c}CPh\cdot NMe\\ \| \qquad\qquad\ \diagdown\!\!\!\!> C\!:\!N\cdot C_6H_4Me,\\ CH\!\!-\!\!\!-\!\!\!-\!\!S\end{array}$$
obtained in the form of its *methiodide*, large needles, m. p. about 200° (decomp.), by heating 2-*p*-toluidino-4-phenylthiazole with methyl iodide in methyl alcoholic solution, crystallises in colourless leaflets, m. p. 118°. It has also been prepared by the condensation of *s-p*-tolylmethylthiocarbamide with ω-bromoacetophenone; the *hydrochloride* and *picrate*, m. p. 158°, are described. When heated with carbon disulphide, it yields *p*-tolylthiocarbimide and 2-*thion-4-phenyl-3-methyl-thiazoline*,

$$\begin{array}{c}CS\cdot NMe\\ \| \qquad\qquad\ \diagdown\!\!\!\!> CPh,\\ S\!\!-\!\!\!-\!\!CH\end{array}$$

which crystallises in pale yellow needles, m. p. 127°.

2-p-*Tolylimino-4-phenyl-5-benzyl-3-methylthiazoline*,

$$\begin{array}{c}CPh\!\!-\!\!\!-\!\!\!-\!\!NMe\\ \| \qquad\qquad\qquad\ \diagdown\!\!\!\!> C\!:\!N\cdot C_6H_4Me,\\ C(CH_2Ph)\cdot S\end{array}$$
prepared by the action of methyl iodide on 2-*p*-tolylimino-4-phenyl-5-benzylthiazole, forms colourless prisms, m. p. 151°, and yields a *hydrochloride*, and a *methiodide*, crystallising in needles, m. p. about 250° (decomp.). It is resolved by carbon disulphide into *p*-tolylthiocarbimide, and 2-*thion-4-phenyl-5-benzyl-3-methylthiazoline*,

$$\begin{array}{c}NMe\cdot CPh\\ \| \qquad\qquad\ \diagdown\!\!\!\!> C\cdot CH_2Ph,\\ CS\!\!-\!\!\!-\!\!\!-\!\!S\end{array}$$

which forms silvery, lustrous leaflets, m. p. 116°.

5-*Bromo-* 2 - p - *toluidino-4-phenylthiazole*, obtained by brominating 2 -*p*- toluidino - 4 - phenylthiazole in benzene solution, crystallises in colourless leaflets or needles, which melt and decompose at 134°, yielding *p*-tolylthiocarbimide; the *hydrobromide*, m. p. 179° (decomp.), and *acetyl* derivative, m. p. 142·5°, crystallise in colourless prisms. It is reduced by zinc and acetic acid to the original thiazole. Attempts to prepare the bromothiazole by the condensation of *p*-tolylthiocarbamide with di-ω-bromoacetophenone yielded a *substance*, m. p. 142° (decomp.).

When warmed with amyl nitrite in alcoholic solution, 2-*p*-toluidino-4-phenylthiazole yields the 5-*nitroso*-derivative,

$$\begin{array}{c}CPh\!\!-\!\!\!-\!\!N\\ \| \qquad\quad\ \diagdown\!\!\!\!> S\cdot NH\cdot C_6H_4Me.\\ C(NO)\cdot S\end{array}$$
This separates in yellowish-brown leaflets, m. p. 184° (decomp.), yields a *hydrochloride*, red needles, an *acetyl* derivative, lustrous, dark red leaflets, m. p. 163°, and is reduced by zinc and acetic acid in alcoholic solution to the corresponding *amino*-compound, which, however, could not be isolated in a pure condition.

On treatment with cold aqueous alkalis it becomes brown, probably owing to the formation of salts derived from the tautomeric form (see VI, next page); when boiled with aqueous alkalis it undergoes com-
plete decomposition, yielding hydrogen sulphide, p-tolylthiocarbimide, carbon dioxide, thiocyanic acid, benzoic acid, ammonia, and p-toluidine.

The *silver* salt, $C_{16}H_{12}ON_3SAg$, prepared by treating an alcoholic solution of the nitroso-compound with the equivalent amounts of ammonia and silver nitrate, separates as an indistinctly crystalline, red precipitate which readily decomposes and explodes when rapidly heated.

On treatment with benzoyl chloride, a solution of the nitroso-compound in aqueous alkalis yields benzoyl-p-tolylcyanamide (Heller and Bauer, A., 1902, i, 444), benzoic and thiocyanic acids. This reaction, which establishes the position of the nitroso-group in the thiazole ring, takes place according to the following scheme :

VI. $C_6H_4Me \cdot N : C \underset{S}{\overset{N : CPh}{\diagdown}} C : NOH \xrightarrow{H_2O + B_4Cl}$

$C_6H_4Me \cdot NBz \cdot C(: NH) \cdot S \cdot C(: NOH) \cdot COPh \longrightarrow$
$C_6H_4Me \cdot NBz \cdot C : N + HS \cdot C : N + OH \cdot COPh.$

5-Bromo-2-p-tolylnitrosoamino-4-phenylthiazole,
$\underset{CBr-S}{\overset{CPh \cdot N}{\diagdown}} C \cdot N(C_7H_7) \cdot NO,$

prepared by warming 5-bromo-2-p-toluidino-4-phenylthiazole with amyl nitrite, forms colourless needles, m. p. 220°.

2-p-Toluidino-4-phenylthiazole combines with benzenediazonium chloride in alcoholic solution, yielding *5-benzeneazo-2-p-toluidino-4-phenylthiazole,* $C_6H_4Me \cdot NH \cdot C \underset{S}{\overset{N \cdot CPh}{\diagdown}} C \cdot N : NPh$, which crystallises in orange-red needles, m. p. 191°, and forms an *acetyl* derivative, $C_{24}H_{20}ON_4S$, red prisms, m. p. 217°, and a *hydrochloride*, crystallising in dark violet-red needles having a greenish glance, m. p. 184° (decomp.).

5-p-Nitrobenzeneazo-2-p-toluidino-4-phenylthiazole, obtained in a similar manner from p-nitrobenzenediazonium chloride, crystallises in dark red needles, m. p. 245° (decomp.) ; the *hydrochloride*, reddish-violet needles, and *acetyl* derivatives, red needles, both melt indefinitely at 250°.

The authors have also studied the behaviour of the remaining aminothiazoles and iminothiazolines described in this paper towards diazonium salts, and find that the iminothiazolines in no circumstances couple with the diazonium salts, whilst the aminothiazoles, in which the 5-position is unsubstituted, readily combine, yielding azo-compounds. The behaviour of 5-bromo-2-p-toluidino-4-phenylthiazole is, however, exceptional, the action of benzenediazonium chloride leading to the removal of the bromine atom and the formation of the above-mentioned 5-benzeneazo-2-p-toluidino-4-phenylthiazole. The reaction towards diazonium salts thus furnishes a ready means of distinguishing whether the product obtained by the condensation of a monosubstituted thiocarbamide with ω-bromoacetophenone and analogous halogeno-ketones is an aminothiazole or iminothiazoline.
2-p-*Toluidino*-4 : 5-*diphenylthiazole,* $\underset{CPh \cdot S}{\overset{CPh \cdot N}{\diagdown}} C \cdot NH \cdot C_6H_4Me$, pre-

pared from desyl bromide and *p*-tolylthiocarbamide, crystallises in colourless needles, m. p. 178°, and forms a *hydrochloride*.

The condensation of ω-bromoacetophenone and allylthiocarbamide yields 2-*allylamino*-4-*phenylthiazole*, $\begin{matrix} CPh \cdot N \\ \| \quad \quad \searrow C \cdot NH \cdot C_3H_5 \\ CH \!\!-\!\! S \end{matrix}$, which has m. p. 73°, and couples with diazonium salts to form red azo-compounds.　　　　　　　　　　　　　　　　　　　　　　　　　F. B.

Decomposition of Alkylidenehydrazines. NICOLAI M. KISHNER (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1754—1759).—*Menthylidene-hydrazine*, $CH_2 \!\!<\!\! \begin{matrix} CH_2 \cdot CHPr \\ CHMe \cdot CH_2 \end{matrix} \!\!>\!\! C{:}N \cdot NH_2$, is a colourless liquid, b. p. 144°/30 mm., 248—249°/759 mm., D_0^{20} 0·9333, n_D 1·4940, $[\alpha]_D - 52\ 45°$. When distilled under reduced pressure, it leaves a viscous residue which, on treatment with 10% sulphuric acid in the cold, yields menthone and *l*-menthazine (compare A., 1908, i, 91). Pure menthylidenehydrazine yields no menthazine with cold 10% sulphuric acid, the sole product being menthone, which exhibits a low specific rotation owing to partial inversion. Distillation of the base with platinised porous tile yields hydrazine and *l*-menthazine. Menthylidenehydrazine is slightly decomposed, with evolution of nitrogen, when distilled with fused potassium hydroxide, whilst in presence of both platinised porous tile and fused alkali, it is resolved into nitrogen and menthane.

*iso*Thujylidenehydrazine, $CMe \!\!<\!\! \begin{matrix} CHPr^{\beta} \cdot CH_2 \\ CMe \!\!-\!\! C{:}N \cdot NH_2 \end{matrix}$, prepared from *iso*thujane and hydrazine hydrate, is a faint yellow, viscous liquid, b. p. 143—144°/17 mm., 152—153°/25 mm., D_0^{20} 0·9579, n_D 1·5328. Distillation of the base in presence of potassium hydroxide, spongy platinum, or molecular silver yields (1) nitrogen, (2) hydrazine, (3) a mixture of the hydrocarbons, $C_{10}H_{18}$ and $C_{10}H_{16}$, giving a cherry-red coloration with sulphuric acid and acetic anhydride and a green one with sulphuric acid and methyl alcohol, and (4) iso*thujazine*,

$$C_{10}H_{16}{:}N_2{:}C_{10}H_{16},$$

which crystallises in golden-yellow needles, m. p. 161—162°.

When distilled with potassium hydroxide, carvylidenehydrazine yields a *hydrocarbon*, $C_{10}H_{16}$, b. p. 175—176°/749 mm. (175—176°/757 mm.), D^{20} 0·8361 (0·8349), n_D 1·4678 (1·4665), $[\alpha]_D - 36·74°$ (−35·36°), which with hydrogen bromide gives the *dipentene hydrobromide*, $C_{10}H_{16},2HBr$, m. p. 63°, and with ethyl nitrite and hydrochloric acid, *l*-limonene β-nitrosochloride.　　　　　　　\ T. H. P.

Hydantoins. XX. Action of Thiocyanates on α-Amino-acids. TREAT B. JOHNSON (*Amer. Chem. J.*, 1913, **49**, 68—69).—It has been shown in earlier papers that by the action of thiocyanates on acyl derivatives of α-amino-acids, acylthiohydantoins are produced. The author has now found that the salt used in certain experiments (A., 1912, i, 53, 316, 390, 807) which was supposed to be potassium thiocyanate was really the ammonium salt, and the yields recorded were therefore obtained from the latter. The two salts show a remarkable difference in their behaviour with hippuric acid; the same com-

pound is formed in each case, but with the potassium salt it is obtained as an oily product which only slowly solidifies, whilst when prepared from the ammonium salt it solidifies at once on being poured into water.   E. G.

Tetraphenyldi-iminotetrahydromiazthiole (3:5-Diphenyl-imino-1:4-diphenyltetrahydro-1:2:4-thiodiazole). EMIL FROMM [with WILHELM BITTERICH] (*Annalen*, 1912, **394**, 284—290).— 3:5-Diphenylimino-1:4-diphenyltetrahydro-1:2:4-thiodiazole is probably a direct product of the oxidation of diphenylthiocarbamide, and is not formed through the intermediate production of an unstable disulphide (compare Fromm and Heyder, A., 1909, i, 903). It is best prepared by Hugershoff's method of oxidation by alcoholic bromine, care being taken to work in the cold, otherwise triphenylguanidine is obtained. The substance is converted into triphenylguanidine by concentrated hydrochloric acid, and is decomposed by boiling glacial acetic acid into acetanilide and 1-anilinobenzothiazole. By heating with aniline at 110° for several hours, the diphenyliminodiphenyltetrahydrothiodiazole is converted into the isomeric *triphenylguanidobenzothiazole*, NHPh·C(:NPh)·NPh·C$\underset{S}{\overset{N}{<}}C_6H_4$, m. p. 142°, which is not desulphurised by lead oxide and an alkali, and yields by the Schotten-Baumann process 2-*benzoylphenylaminobenzothiazole*,

$$C_6H_4\underset{S}{\overset{N}{<}}C·NPh·COPh,$$
m. p. 156°, which is also obtained from 2-anilinobenzothiazole, benzoyl chloride, and aqueous sodium hydroxide.   C. S.

Trimethylparamide. HANS MEYER and KARL STEINER (*Ber.*, 1912, **45**, 3676—3677. Compare Mumm and Bergell, A., 1912, i, 1015).—Trimethylparamide can be prepared in a pure condition by heating methylamine mellitate for two hours in a sealed tube at 200° and recrystallising the colourless product from chlorobenzene; it is quantitatively hydrolysed to mellitic acid on prolonged boiling with potassium hydroxide solution.   D. F. T.

Disulphides with Neighbouring Double Linkings. Derivatives of Dithiobiurets and of Thiurets. EMIL FROMM [and RICHARD HEYDER, ADOLF JUNG, and MARGRET STURM] (*Annalen*, 1912, **394**, 258—284).—Since only one example is known of the simultaneous production of an arylguanidoarylthiocarbamide and a diarylguanidothiocarbamide by the decomposition of an arylthiuret by an aromatic amine (A., 1908, i, 700), the action of different aromatic amines on a series of thiurets has been examined. It is found that, as a rule, the two products of the decomposition are formed when the arylthiuret and the aromatic amine contain the same aromatic group.

o-*Anisyldithiobiuret*, C$_9$H$_{11}$ON$_5$S$_2$, m. p. 153°, yellowish-white needles, obtained by heating equal weights of perthiocyanic acid and o-anisidine on the water-bath, is converted by boiling hydrochloric acid and ferric chloride into o-*anisylthiuret hydrochloride*, C$_9$H$_9$ON$_5$S$_2$,HCl, m. p. 220° (hydrated) or 235° (anhydrous). The latter and o-anisidine in

boiling alcohol yield sulphur, o-*anisylguanido-o-anisylthiocarbamide,*
OMe·C_6H_4·NH·CS·NH·C(:NH)·NH·C_6H_4·OMe (the constitution of
which is proved by its conversion into o-*anisylguanido-o-anisyl-ψ-
benzylthiocarbamide,*
OMe·C_6H_4·N:C(S·C_7H_7)·NH·C(:NH)·NH·C_6H_4·OMe,
m. p. 116°, by boiling with benzyl chloride and an excess of aqueous
alcoholic sodium hydroxide), and *di-o-anisylguanidothiocarbamide,*
which is isolated as the *hydrochloride,*
C(NH·C_6H_4·OMe)$_2$:N·CS·NH$_2$,HCl,
m. p. 205°. By boiling this hydrochloride with lead oxide and
alcoholic sodium hydroxide, *di-o-anisyldicyanodiamide,*
CN·N:C(NH·C_6H_4·OMe)$_2$,
m. p. 168°, white needles, is obtained. In a similar manner, *p*-phene-
tylthiuret hydrochloride and *p*-phenetidine in boiling alcohol yield
di-p-phenetylguanidothiocarbamide, m. p 142° (*hydrochloride,* m. p. 167°),
and p-*phenetylguanido-p-phenetylthiocarbamide,* m. p. 172°, of which the
former is converted into *di-p-phenetyldicyanodiamide,* m. p. 176°, by
lead oxide and alcoholic sodium hydroxide, and the latter into p-*phenetyl-
guanido-p-phenetyl-ψ-benzylthiocarbamide,* m. p. 180°, by benzyl chloride
and alcoholic sodium hydroxide. *p*-Phenetylthiuret hydrochloride and
aniline react to form phenylguanido-*p*-phenetylthiocarbamide, m. p.
184°, not 170° (A., 1907, i, 982), and a small amount of *phenyl-p-
phenetylguanidothiocarbamide,* OEt·C_6H_4·NH·C(NHPh):N·CS·NH$_2$,
m. p. 137°, the *hydrochloride* of which, $C_{16}H_{18}ON_4S$,HCl,H$_2$O, has m. p.
113—114°.

p-Phenetylguanidophenylthiocarbamide (*loc. cit.*) has m. p. 158°,
not 168°, and forms a *hydrochloride,* m p. 168°.

o-*Tolylthiuret hydrochloride,* $C_9H_9N_3S_2$,HCl,2H$_2$O, m. p. 175°, obtained
from *o*-tolyldithiobiuret and boiling hydrochloric acid and ferric
chloride, reacts with *o* toluidine in boiling alcohol to form *tri-o-tolyl-
diguanide hydrochloride,* $C_{23}H_{25}N_5$HCl, m. p. 233°, from which *tri-o-
tolyldiguanide,* C(NH·C_6H_4Me)$_2$·N·C(:NH)·NH·C_6H_4Me, m. p. 179°,
is liberated by ammonia. The by-product of the preceding reaction is
di-o-tolylguanidothiocarbamide, m. p. 172°, or o-*tolylguanido-o-tolylthio-
carbamide,* $C_{16}H_{18}N_4S$,EtOH, m. p. 178°, according to the dilution of
the solution. *o*-Tolylthiuret and aniline in boiling alcohol yield only
phenylguanido-o-tolylthiocarbamide, m. p. 135° (*hydrochloride,* m. p. 183°),
and phenylthiuret and *o*-toluidine under similar conditions yield only
phenyl-o-tolylguanidothiocarbamide, m. p. 111° (*hydrochloride,* m. p.
89°). *Phenylguanido-o-tolyl-ψ-benzylthiocarbamide,* $C_{22}H_{22}N_4S$, m. p.
124°, crystallises in yellow octahedra.

The following substances have been obtained by the interaction of
arylthiuret hydrochlorides and phenylhydrazine in boiling alcohol
(A., 1907, i, 982; 1908, i, 700), and are converted into triazole
derivatives by boiling aqueous alcoholic alkalis; thus *o*-tolylthiuret
hydrochloride and phenylhydrazine yield *anilguanido-o-tolylthiocarb-
amide* or *anil-o-tolylguanidothiocarbamide,*
NHPh·NH·C(:NH)·NH·CS·NH·C_6H_4Me or
NHPh·NH·C(NH·C_6H_4Me):N·CS·NH$_2$, m. p. 157° [3 : 5(or 5 : 3-)-
amino-o-toluidino-]-*phenyltriazole,* NPh$\genfrac{}{}{0pt}{}{N{=\!=\!=\!=}C·NH_2}{C(NH·C_6H_4Me):N}$ or

NPh$\underset{C(NH_2):N}{\overset{N=\!\!=\!\!=C:NH·C_6H_4Me}{\diagdown}}$, has m. p. 143°] ; o-anisylthiuret and

phenylhydrazine yield two substances which could not be obtained pure, but have been converted into 5-*amino*-3-*o-anisidino* 1-*phenyltriazole*,

OMe·C$_6$H$_4$·NH·C$\underset{N:C·NH_2}{\overset{N·NPh}{\diagdown}}$, and 3-*amino*-5-*o-anisidino*-1-*phenyl-triazole*, one of which forms a sparingly soluble *hydrochloride*,

$$C_{15}H_{15}ON_5,HCl,H_2O,$$

m. p. 228°, and a *picrate*, m. p. 250°, red needles, and the other an easily soluble *hydrochloride*, and a *picrate*, m p. 169° ; *p*-phenetyl-thiuret hydrochloride and phenylhydrazine (Fromm and Vetter, A., 1907, i, 982) yield anilguanido-*p*-phenetylthiocarbamide or anil-*p*-phenetylguanidothiocarbamide, m. p. 170°, not 168°, and aminophenyl-guanido-*p*-phenetylthiocarbamide or aminophenyl-*p*-phenetylguanido-thiocarbamide, m. p. 168°, white needles (not m. p. 236°, white leaflets), the latter forming a *benzylidene* derivative, m. p. 183°.

The formation of 3-amino-5-thiol-1-phenyltriazole, m. p. 234°, and dianildithiobiuret, m. p. 178°, from phenylhydrazine and phenyl-methylthiuret has already been recorded (A., 1908, i, 700). The former reacts with benzyl chloride and aqueous sodium hydroxide to form 3-*amino*-5-*benzylthiol* 1-*phenyltriazole*, m. p. 116°, and with benzoyl chloride and aqueous sodium hydroxide to form 3-*benzoylamino*-5-*thiol*-1-*phenyltriazole*, m. p. 267°, from which 3-*benzoylamino*-5-*benzyl-thiol*-1-*phenyltriazole*, m. p. 161°, is obtained by means of benzyl chloride and aqueous sodium hydroxide. The action of benzoyl chloride and sodium carbonate on dianildithiobiuret or on 3-thiol-5-phenylhydrazino-1-phenyltriazole yields 3-*thiol*-5-*benzoylphenylhydr-azino*-1-*phenyltriazole*, NHPh·NBz·C$\underset{N\!-\!\!-\!C·SH}{\overset{NPh·N}{\diagdown}}$, m. p. 218°, which

yields the 3-*benzylthiol* derivative, m. p. 171°, by boiling with benzyl chloride and the calculated quantity of aqueous alcoholic sodium hydroxide, and 3-*benzylthiol*-5-*phenylhydrazino* 1-*phenyltriazole*, m. p. 118°, red needles, when an excess of the alkali is employed. The substance, m. p. 218°, obtained by the action of acetic anhydride on dianildithiobiuret (*loc. cit.*) is 3-*thiol*-5-*acetylphenylhydrazino*-1-*phenyl-triazole* ; by treatment with benzyl chloride and an alkali, it yields 3-*benzylthiol*-5-*acetylphenylhydrazino*-1-*phenyltriazole*, m. p. 102°, yellow leaflets. The constitution of the oxidation product, m. p. 218°, of 3-thiol-5-phenylhydrazino-1-phenyltriazole as a benzeneazotriazole (*loc. cit.*) is proved as follows. In the presence of an alkali, the sub-stance is converted into 5-*benzeneazo*-3-*thion*-2-*benzoyl*-1-*phenyltriazole*,

PhN$_2$·C$\underset{N\!-\!\!-\!CS}{\overset{NPh·NBz}{\diagdown}}$, m. p. 167°, red needles, by benzoyl chloride, and

into 5 *benzeneazo*-3-*benzylthiol*-1-*phenyltriazole*,

$$PhN_2·C\underset{N\!-\!\!-\!C·SC_7H_7}{\overset{NPh·N}{\diagdown}},$$
m. p. 116°, reddish-yellow leaflets, by benzyl chloride. The latter is also produced when the former is treated with benzyl chloride and an alkali. The oxidation product can be acylated or alkylated, but not

both simultaneously, thus proving that the same hydrogen atom is concerned in each process and that the substance is tautomeric.

The base $C_{14}H_{13}N_5S$, m. p. 181°, which is obtained together with the preceding azo-compound by the action of boiling hydrochloric acid on dianildithiobiuret (*loc. cit.*), forms, in addition to the diacetyl and the dibenzylidene derivatives already described, a *dibenzoyl* derivative, m. p. 216°, does not react with benzyl chloride in the presence of an alkali, and requires 2 mols. of sodium nitrite for its diazotisation. These facts are contrary to the formula previously ascribed to the base, and are more in harmony with the constitution :

$$NH_2 \cdot C_6H_4 \cdot N\text{:}C\underset{NH}{\overset{-S}{<}}C\text{:}N \cdot C_6H_4 \cdot NH_2.$$
Under the influence of hydrogen chloride, substituted dithiobiurets react with aldehydes or ketones to form aldurets or keturets (A, 1893, i, 575; 1906, i, 656), which can be alkylated in consequence of the presence of the thiol groups; thus *o*-tolyldithiobiuret and acetone yield *o-tolyldimethyl-ψ-dithioketuret*, $C_6H_4Me \cdot N\text{:}C(SH) \cdot N\underset{CMe_2}{\overset{C(SH)}{<}}N$, m. p. 236°, which forms a *benzyl* derivative. m. p. 192°, and a *dibenzyl* derivative, m. p. 83°; *o*-tolyldithiobiuret and benzaldehyde yield *phenyl-o-tolyl-ψ-dithioalduret*, $C_6H_4Me \cdot N\text{:}C(SH) \cdot N\underset{CHPh}{\overset{C(SH)}{<}}N$, m. p. 207°, yellow leaflets (*dibenzyl* derivative, m. p. 118°); *o*-tolyldithiobiuret and 40% formaldehyde yield *o-tolyl-ψ-dithioalduret*,

$$C_6H_4Me \cdot N\text{:}C(SH) \cdot N\underset{CH_2}{\overset{C(SH)}{<}}N,$$
m p. 197°, yellow leaflets (*dibenzyl* derivative, m. p. 80°). o-Tolyl-dithiobiuret does not react with acetophenone or benzophenone.

C. S.

Crystallographic Study of the Sodium Salt of *iso*Hydroxy-tetrazole. ARISTIDE ROSATI (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 645—648).—The author has studied the salt $CHON_4Na,3H_2O$, which was obtained by Palazzo (A., 1910, i, 342). The salt loses its water at 120—130°, and explodes at 240°. It occurs in two crystalline forms: (1) pale straw-yellow tablets belonging to the pinacoidal class of the triclinic system; $a:b:c = 1\cdot2494:1:0\cdot8521$, α 130°6′, β 114°47′, γ 79°34·5′; (2) colourless tablets, also belonging to the pinacoidal class of the triclinic system ;

$a:b:c = 0\cdot6798:1:1\cdot0834$, α 54°53′, β 124°32·5′, γ 121°43′.

R. V. S.

Action of Chlorine on Ethyl Phenylazoacetoacetate. A New Way to Prepare Derivatives of Formimido-chloride. CARL BÜLOW and PETER NEBER (*Ber.*, 1912, 45, 3732—3744).— Elimination of the carbethoxyl group takes place when ethyl phenyl-azoacetoacetate is hydrolysed by sodium hydroxide (Richter and Münzer, A., 1884, 1342) or brominated (Hecking, *Diss.*, 1910). The action of chlorine, however, results in the removal of the acetyl group and the formation of the dichlorophenylhydrazone of ethyl mono-chloroglyoxylate. When this substance is completely reduced,

2 : 4-dichloroaniline is formed, and the compound may also be synthesised from this base. The remaining chlorine atom must necessarily be attached to the α-carbon atom of the side-chain, and it is very reactive. It may be replaced by an amino-group, more prolonged action of ammonia replacing, in addition, the ester group.

A method is given for the preparation of ethyl phenylazoaceto-acetate. Chlorination may be effected in glacial acetic acid by chlorine or sulphuryl chloride, but the best results are obtained by chlorine in chloroform. The 2 : 4-*dichlorophenylhydrazone* of *ethyl α-chloroglyoxylate*, $C_6H_3Cl_2·NH·N:CCl·CO_2Et$, crystallises in brilliant needles, m. p. 98°. When treated with alcoholic potash, hydrogen chloride is eliminated, and a *product*, $C_{10}H_8O_2N_2Cl_2$, is obtained in beautiful yellow needles, m. p. 196°. Its constitution is probably represented by the annexed formula. The 2 : 4-*dichlorophenylhydrazone* of *ethyl α-amino-glyoxylate*, $C_{10}H_{11}O_2N_3Cl_2$, which is immediately formed when alcoholic ammonia is added to the imido-chloride, crystallises in long, flat needles from dilute ethyl acetate, m. p. 99°, and is readily soluble in mineral acids, but does not form a diazonium salt. More prolonged action of ammonia results in the formation of the *amide*, $C_6H_3Cl_2·NH·N:C(NH_2)·CO·NH_2$, in long, grey needles, m. p. 170°.
Ethyl 2 : 4-*dichlorobenzeneazoacetoacetate*, $C_6H_3Cl_2·N_2·CHAc·CO_2Et$, may be prepared in a similar manner by condensing the diazotised dichloroaniline with ethyl acetoacetate. It crystallises in yellow needles, m. p. 127°, and gives the above α-chloro-compound with chlorine. When condensed with hydrazine hydrate, it gives 4-o-p-*dichlorobenzeneazo-5-hydroxy-3-methylpyrazole*, $C_{10}H_8O_2N_3Cl_2$, in orange-yellow needles, m. p. 207°, which cannot be precipitated by water from piperidine, in which the substance is very soluble.

Similarly, phenylhydrazine yields 4-o-p-*dichlorobenzeneazo-5-hydroxy-1-phenyl-3-methylpyrazole*, $C_{16}H_{12}ON_4Cl_2$, in brick-red needles, m. p. 195°, which concentrated nitric acid converts into 2 : 4-dichlorophenyl-diazonium chloride and 4-nitro-1-benzene-3-methylpyrazolone (compare A., 1910, i, 902). J. C. W.

The Racemisation of Proteins and their Derivatives Resulting from Tautomeric Change. I. HENRY D. DAKIN (*J. Biol. Chem.*, 1912, 13, 357—362).—There is an analogy between the hydantoin, $NH<^{CO-NH}_{CRH·CO}$, and peptide,

$$RCH<^{NH·CO-}_{CO·NH·CHR·CO_2H},$$
groupings, in both of which the –CH·CO– group can exhibit keto-enolic tautomerism and hence racemisation (compare Dakin, A., 1910, i, 590). In the peptide complex the terminal amino-acid containing a free carboxyl group cannot, however, undergo this change. Such tautomeric change apparently takes place when a protein is digested at low temperatures with dilute alkali (compare Kossel and Weiss, A., 1909, i, 542; 1910, i, 791).

The optical rotatory power of gelatin falls to a minimum when it is digested with dilute alkali. On subsequent hydrolysis with acids, inactive leucine, aspartic acid, arginine, histidine, and phenylalanine are obtained, whereas proline, glutamic acid, and lysine are obtained in the optically active forms together with part of the alanine. The conclusion is drawn that none of the carboxyl groups in the substances which were obtained inactive are free in gelatin. On the other hand, glutamic acid, lysine, and alanine may have some of their carboxyl groups free, that is, they may occupy terminal positions in the peptide chains. An alternative is that these amino acids are rapidly liberated in the free state by the hydrolytic action of the alkali and so escape racemisation. E. F. A.

The Refractive Indices of Solutions of Certain Proteins. VIII. Globin. T. BRAILSFORD ROBERTSON (*J. Biol. Chem.*, 1913, 13 455—462).—Globin was prepared from ox-corpuscles by three different modifications of Schulz's method. The value of a for the purest preparation dissolved in decinormal potassium hydroxide or hydrochloric acid is 0.00169 ± 0.00005. W. D. H.

The Preparation and Properties of a Compound Protein; Globin Caseinate. T. BRAILSFORD ROBERTSON (*J. Biol. Chem.*, 1913, 13, 499—506).—Globin caseinate may be prepared by mixing two parts of globin with one of casein, each in a faintly alkaline solution. It displays properties intermediate between those of the two component proteins, the acid function of globin being enhanced by union with casein and the basic function of casein by union with globin.

The compound is not decomposed by dilute acetic acid in the cold, but it is by boiling dilute acetic acid, or by pepsin and acetic acid. The change in the refractive index of decinormal potassium hydroxide due to the introduction of 1% of globin caseinate is 0.00162 ± 0.00005. The refractivity of a compound protein is an additive function of the refractivities of its components. W. D. H.

Constitution of the Blood and Bile Pigments. I. HANS FISCHER and ERICH BARTHOLOMÄUS (*Zeitsch. physiol. Chem.*, 1913, 83, 50—71).—The formation of tri- and tetra-substituted pyrroles on the decomposition of hæmin is explained on the hypothesis that the pyrrole nuclei are united by a CH_2 radicle in the 2-positions. Such 2- and 3-methylene derivatives have been synthesised by Colacicchi (A., 1912, i, 491).

Bis-(5-acetyl-2 : 4-dimethylpyrryl)methane, in which the methylene group is in the 3-position, resists the reducing action of hydrogen iodide and acetic acid during two hours. To some extent the a-acetyl residue is eliminated and *bis-(2 : 4-dimethylpyrryl-3 : 3')methane*,

$$NH\begin{matrix} OMe:C—CH_2—C:CMe \\ CH=CMe \quad MeC=CH \end{matrix}NH,$$

is formed. This compound has many of the properties of hemibilirubin; it gives the aldehyde reaction, is unstable, shows the urobilin bands, and the fluorescence reaction with zinc acetate. It forms a *picrate* and an a-azo-dye.

When the action of the reducing agent is prolonged for fourteen to sixteen hours, 2 : 3 : 4-trimethylpyrrole admixed with some 2 : 4-dimethylpyrrole is obtained.

Bis-(3-acetyl-2 : 4-dimethylpyrryl)methane (Colacicchi, *loc. cit.*) is readily reduced to pyrrole derivatives by acetic acid and hydrogen iodide. The mixture of pyrrole picrates was not separated.

Trialkylated pyrroles condense with formaldehyde in presence of alkali. The products are regarded as methylene derivatives, although the possibility of an alcohol structure, $NH\!\!<^{CMe\vdots C\cdot CH_2\cdot OH}_{CMe\vdots CMe}$, is not overlooked.

Tetramethylpyrrole was obtained on reducing the condensation product from 2 : 4 : 5-trimethylpyrrole; phyllopyrrole from the condensation product of cryptopyrrole.

2 : 3 : 5-*Trimethylpyrrole-4-propionic acid*,

$$NH\!\!<^{CMe\vdots C\cdot CH_2\cdot CH_2\cdot CO_2H}_{CMe\vdots CMe},$$
was not obtained on reducing the amorphous condensation product of formaldehyde with phonopyrrolecarboxylic acid, but it is readily formed on methylation of phonopyrrolecarboxylic acid. Tetramethylpyrrole is obtained at the same time.

The pyrrole, $CO_2Et\cdot C\!\!<^{CMe\vdots C—CH_2—C\,=CMe}_{CMe\cdot NH\quad\quad NH\cdot CMe}\!\!>C\cdot CO_2Et$, obtained by the action of formaldehyde on 3-carbethoxy-2 : 4-dimethylpyrrole, when boiled with acetic acid gives an intense green solution showing a characteristic band in the red similar to that of the copper salt of hemibilirubin.

Bis-5-acetyl-2 : 4-dimethylpyrrylethane,

$$NH\!\!<^{CMe=\!\!=\!\!C—CHMe—C=\!\!=\!\!CMe}_{C(COMe)\vdots CMe\quad\quad MeC\cdot C(COMe)}\!\!>NH,$$
produced from 5-acetyl-2 : 4-dimethylpyrrole by the action of acetaldehyde, is decomposed by acetic acid and hydrogen iodide into 2 : 4-dimethylpyrrole. The formation of cryptopyrrole could not be determined.

All the foregoing pyrrole derivatives are decomposed by sodium methoxide, forming tetramethylpyrrole.

Tripyrrole is absolutely stable towards acetic acid and hydrogen iodide in the sense that no volatile bases are formed.

Bis-(2 : 4-dimethylpyrryl-3 : 3')methane crystallises in tiny pyramids and prisms, m. p. 139—140°; the *picrate* forms yellowish-brown needles, m. p. 125—126°.

2 : 3 : 5-*Trimethylpyrrole-4-propionic acid* forms a picrate, m. p. 126—127°.　　　　　　　　　　　　　　　　　　　　　　　　　E. F. A.

Bilirubin and Hæmin. WILLIAM KÜSTER [and P. DEIHLE] (*Zeitsch. physiol. Chem.*, 1912, 82, 463—483).—Sodium amalgam does not necessarily reduce vinyl groups, which remain unattacked during the conversion of hæmin into the leuco-compound or of bilirubin into hemibilirubin. The complex giving rise to methylethylmaleinimide on oxidation is contained already in bilirubin. One of the two complexes

in hæmin which gives hæmatic acid on oxidation loses carbon dioxide during conversion into bilirubin, and so gives rise to the imide when oxidised. On esterification with methyl alcohol and hydrochloric acid, bilirubin behaves differently from hæmin. A dimethyl derivative is obtained, in which one methyl replaces hydrogen, and the other is due to the addition of methyl alcohol.

The formulæ given by Piloty (A., 1912, i, 923) and by H. Fischer and Röse (A., 1912, i, 575) for bilirubic acid, etc., are discussed, and a complete structural formula for hæmin is suggested.

Pure mesoporphyrin yields methylethylmaleinimide on oxidation.

Bilirubin forms a silver salt containing 4 atoms of silver when fresh preparations are used ; older preparations react with 2 atoms only of silver. The salts have a metallic lustre, and the silver is not replaceable by barium. Bilirubin regenerated from the zinc salt dissolves in sodium hydrogen carbonate. This *aci*-form is more soluble in chloroform than the normal. *Dimethylbilirubin*, $C_{34}H_{40}O_7N_4$, is a blackish-green powder. E. F. A.

The Action of Yeast on Yeast-nucleic Acid. SAMUEL AMBERG and WALTER JONES (*J. Biol. Chem.*, 1913, 13, 441—446).— Yeast has no action on thymus-nucleic acid, but it causes the disappearance of yeast-nucleic acid. If compressed yeast is used, adenine and guanine appear ; if yeast powder is employed, adenine and guanosine are found. W. D. H.

Nucleases. III. PHŒBUS A. LEVENE and F. B. LA FORGE (*J. Biol. Chem.*, 1913, 13, 507—510).—The pyrimidine ribosides are more resistant towards the hydrolytic action of mineral acids than are the purine ribosides. Their behaviour to enzymes runs parallel to this. The differences towards acids can be removed by reducing the pyrimidine base in the riboside to the corresponding dihydropyrimidine. No tissue enzyme has, however, yet been discovered which hydrolyses either the original or the dihydro-derivative.

W. D. H.

Influence of the Reaction of the Medium on the Action of Ptyalin. WILHELM E. RINGER and H. VAN TRIGT (*Zeitsch. physiol. Chem.*, 1912, 82, 484—501).—The action of ptyalin on starch is studied in presence of varying amounts of sodium hydroxide and phosphoric acid, and the amount of reducing sugar formed contrasted with the hydrogen-ion concentration of the liquids as determined by the conductivity method. At 37° the optimum activity is observed in a solution having $p_H = 6.0$. When citrate is substituted for phosphate, the position of the optimum varies with the concentration of the citrate ; it is observed in more nearly neutral solutions with citrate than is the case with phosphate. In presence of sodium acetate and acetic acid the optimum is at $p_H = 6.0$. The presence of both phosphate and acetate reduces the amount of starch hydrolysis ; citrate has still more influence. The enzyme itself is not damaged during the duration of the experiment. When these are prolonged for five times as long, the position of the optimum is not materially altered. E. F. A.

Temperatures of Destruction of Emulsin in Ethyl Alcohol of Various Strengths. ÉMILE BOURQUELOT and MARC BRIDEL (*J. Pharm. Chim.*, 1913, [vii], 7, 27—31).—A solution of emulsin in water was diluted with alcohol or alcohol and water to produce alcoholic liquids of various strengths containing the same quantity of emulsin. Portions of these liquids were then heated to various temperatures, and afterwards tested for activity on salicin. It was found that the temperature at which emulsin begins to become inactive under these conditions varies from 60° to 40° for liquids containing from 10 to 50% of alcohol, and remains constant at 45° to 40° for liquids containing 60 to 95% of alcohol. Total destruction of activity occurs at temperatures ranging from 70° to 55°. Different figures are obtained when the preparations are made by macerating emulsin in the alcoholic liquids   T. A. H.

Rennin. I. Properties of the Ferment when Prepared by Different Methods II. Acceleration of the Action of Rennin by Phosphoric Acid. III. The Variation in the Length of Time Required to Curdle Different Specimens of Milk A. ZIMMERMANN (*J. Ind. Eng. Chem.*, 1912, 4, 506—508).—The distinctive properties of rennin when prepared by the following different methods are described : (1) precipitated by sodium chloride, (2) precipitated by sodium sulphate, (3) rennin in scales (granular rennin), and (4) commercial rennin.

Phosphoric acid (0 075%) when added to milk increases the activity of the rennin, a property possessed in a less degree by lactic, hydrochloric, and oxalic acids.

The length of time required to curdle by the same specimen of rennin appears to be influenced by the length of time the milk has been kept; the staler the milk, the more rapid the action of the rennin ; this would appear to be a bacterial effect, yet it is found that a mixture of rennin and milk kept several hours at 40° will not curdle, whereas if the milk alone be subjected to this treatment, the addition of the same rennin causes rapid curdling.

The preparation of standardised rennin, the permanency of rennin solutions and of pepsin are also discussed.   F. M. G. M.

Antagonism between Citrates and Calcium Salts in Milk Curdling by Rennet. J. R KATZ (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, 15, 434—445).—Whilst $N/125$- and $N/25$-solutions of citric acid delay the curdling of milk more than two hours, the action is much weakened when substitution occurs at one of the active groups of the citric acid, and stops altogether when two or three of the groups are made inactive.

When substitution occurs at the alcohol group, the curdling is delayed three and a-half and nine and a-half hours respectively by $N/125$- and $N/25$-solutions. Similar results were obtained by tribasic acids not containing an alcohol group.

When substitution occurs at one carboxyl group in citric acid, a delay in curdling milk of one and a-quarter hours with $N/125$- and of six and a-half hours with $N/25$-solutions takes place. Results similar

to these were again obtained by employing dibasic acids with one or more alcohol groups.

The results show that when one active group is taken from citric acid, the characteristic action of the acid is reduced to about 6% of its original value, and that when two groups are substituted to about 1%.

<div align="right">N. H. J. M.</div>

Synthesising Action between Galactose and Ethyl Alcohol under the Influence of Kephir. EMILE BOURQUELOT and HENRI HÉRISSEY *Compt. rend.*, 1912, 155, 1552—1554).—β-Ethyl galactoside is slowly synthesised, in small quantities in the presence of kephir, from an alcoholic solution of galactose. The authors suggest that the synthesising agent in this case and also in that of emulsin obtained from almonds (compare A., 1912, i, 946) is really the lactase present in these two substances. <div align="right">W. G.</div>

Physiological Chemistry

Variations in the Irritability of the Reflex Arc. I. Variations under Asphyxial Conditions, with Blood-gas Estimations. E. L. PORTER (*Amer. J. Physiol.*, 1913, 31, 223—244).—The experiments were made on the spinal cat, subjected to asphyxial conditions. The records obtained offer no conclusive evidence of increased reflex irritability under asphyxia, but as the oxygen in the blood lessens and the carbon dioxide accumulates, the flexion reflex disappears. This is the general result, but the details differ according as the admixture of the two gases supplied varies. <div align="right">W. D. H.</div>

The Chemistry of Portal Blood. I. A Portal Fistula. EFIM S. LONDON and N. A. DOBROVOLSKAJA (*Zeitsch. physiol. Chem.*, 1912, 82, 415—416).—A description of the operative procedure in making a fistula for the obtaining of blood from the portal vein. Results will follow later. <div align="right">W. D. H.</div>

Glycolysis. III. PETER RONA and F. ARNHEIM (*Biochem. Zeitsch.* 1913, 48, 35—49. Compare A., 1911, ii, 619).—The authors confirm the previous statement that sugar is not destroyed by lysed corpuscles. They now show that if the corpuscles are previously lysed, they can still destroy sugar provided that phosphate or carbonate ions are present in sufficient concentration. They further show that the glycolysis is much diminished if intact corpuscles are diluted with physiological saline alone; if, however, carbonates or phosphates are added in sufficient concentration in a Ringer's fluid, when such a liquid is used to dilute the corpuscles, the glycolysis is not less than that produced by the undiluted corpuscles. The comparative glycolytic

properties of white and red corpuscles was also investigated. The red corpuscles diluted with saline to the volume of the original blood exerted nearly as great a glycolytic effect as the original blood, whereas the white corpuscles diluted to the same extent were almost inactive. Nevertheless, if the white corpuscles are diluted with a liquid containing phosphates, they exert a very marked glycolytic action. In the experiments carried out, no glycolytic power markedly superior to that of the red corpuscles could be demonstrated.

S. B. S.

The Alkalinity of Pancreatic and Intestinal Juice in Living Dogs. FRIEDRICH AUERBACH and HANS PICK (*Arb. K. Gesundheitsamte*, 1912, 43, 155—186).—Both these juices are strongly alkaline in spite of the blood being nearly neutral in reaction; the alkalinity was determined in the juices obtained from fistulæ in dogs by electrometric, colorimetric, and titrimetric methods. It corresponds with that of a sodium hydrogen carbonate solution, rather than with one of sodium carbonate. It is probable that the juices contain free carbon dioxide. The H-ion concentration averages $0\cdot5.10^{-8}$ mol./litre; the OH-ion concentration at 18° is about 10^{-6}, and at 37°, 5.10^{-6} mol./litre.

In intestinal juice, sodium chloride is more abundant than sodium hydrogen carbonate; in pancreatic juice the reverse obtains. The alkalinity of the duodenal contents corresponds with that which is the optimum for peptolytic (not tryptic) activity. W. D. H.

Effects of Nutrition with Maize. IV. Action of the Succus entericus of the Dog on Zein, Gliadin, Zeoses, and Gliadoses. SILVESTRO BAGLIONI [with G. AMANTEA and L. MANINI] (*Atti R. Accad. Lincei*, 1912, [v], 21, ii, 655—660. Compare A., 1911, ii, 999).—The *Succus entericus* of the dog has a weak digestive action on gliadin and an even weaker action on zein, but it has an almost equal digestive action on zeoses and gliadoses of peptic and tryptic origin. R. V. S.

Are the Endogenous Purine Substances the Products of the Activity of the Digestive Organs? FRANZ MAREŠ (*Pflüger's Archiv*, 1912, 149, 275—286).—Polemical against Sivén (A., 1912, ii, 780; compare following abstract). W. D. H.

The Source of Uric Acid in Man. II. FRANZ SMETÁNKA (*Pflüger's Archiv*, 1912, 149, 287—317).—This also is a reply to Sivén's criticism on the work of Mareš (A., 1910, ii, 973) and Smetánka (A., 1911, ii, 218). The article is mainly polemical, but does contain some fresh experimental work, and the main conclusions drawn are as follows. Intake of a purine-free diet causes an increase of purine excretion. This is due to nuclear catabolism occurring in and associated with the activity of the digestive glands. The increase lasts five to six hours after a meal; but when much protein is taken with the evening meal it may go on all night. The question whether variations in the protein intake produce variations in the purine

output is not definitely answered. Diets rich in starch act similarly, but less markedly. The original views of Mares on the question are considered to remain unshaken. W. D. H.

Animal Calorimetry. VII. The Metabolism of a Dwarf. FRANCIS H. McCRUDDEN and GRAHAM LUSK (*J. Biol. Chem.*, 1913, 13, 447—454).—A dwarf, suffering from infantilism, seventeen years old, and weighing 21 kilos., had a basal metabolism of 775 calories per square metre of body surface in twenty-four hours; this is about the same as in a dog. The metabolism was increased by 6·6% after food, and this again by 14·7% by reading illustrated periodicals in bed. The protein metabolism yielded the normal proportion of 15% of the total calories of heat-production. Nothing abnormal in metabolic processes was detected. W. D. H.

The Part Played by Acid in Carbohydrate Metabolism. Acid Diabetes. HERBERT ELIAS (*Biochem. Zeitsch.*, 1913, 45, 120—143).— Relatively small amounts of acids, administered to rabbits, can cause glycogen in large quantities to disappear from the liver; this disappearance results in hyperglycæmia and glycosuria in the animals The fact was established by the distinct positive results obtained in a series of researches in animals with livers rich in glycogen, whereas negative results were obtained from animals in which the livers were glycogen-free. The suprarenals take no part in this action, as positive results were obtained when dyspnœa was avoided, during chloral hydrate narcosis, and after cutting the splanchnics. In all cases, furthermore, the histological structure of the suprarenals remained intact. It was shown also, by perfusion experiments through the isolated liver, that adrenaline plays no part in the disappearance of the glycogen. The acid appears to act, therefore, directly on the liver itself. Perfusion experiments on the isolated liver of tortoises indicated that the glycogen separates from the liver cells for the most part unchanged when acid is added to the perfusion fluid.

S. B. S.

Has Heated Milk the Same Feeding Value as Raw Milk? EICHLOV (*Bied. Zentr.*, 1913, 42, 56—58; from *Mitt. deut. milchwirt. Ver.*, 1912).—Milk when heated loses the property of being coagulated by rennet, and the soluble calcium salts become insoluble; both changes presumably decrease the feeding value of milk.

Experiments in which dogs (ten days old) were fed for several months with fresh milk and boiled milk respectively gave the following results. The bones of the dogs fed with boiled milk, with one exception, contained less ash than when fed with fresh milk; the blood also contained less ash and only about half as much fibrin as the blood of the dogs which had fresh milk. When milk is heated for ninety minutes in boiling water, ammonia and hydrogen sulphide are produced in small amounts; the vapour from the heated milk also contained phosphorus. N. H. J. M.

The Influence of Standing or Lying on the Metabolism of Cattle. HENRY PRENTISS ARMSBY and J. AUGUST FRIES (*Amer. J. Physiol.*, 1913, 31, 245—253).—Details are given of the increase of metabolism in cattle when they are in a standing as compared with the lying position. The increased emission of heat during the standing periods is accompanied with a correspondingly increased elimination of both carbon dioxide and water.   W. D. H.

Nitrogen Retention on Feeding with Urea. EDUARD GRAFE and K. TURBAN (*Zeitsch. physiol. Chem.*, 1913, 83, 25—44).—A full account is given of metabolic experiments in dogs and pigs which show that retention of nitrogen occurs when urea is added to a carbohydrate rich diet. Sometimes equilibrium was attained; a small part of the nitrogen was excreted in the after period.   W. D. H.

Histochemistry of Spermatozoa. III. HERMANN STEUDEL (*Zeitsch. physiol. Chem.*, 1913, 83, 72—78).—Dried defatted spermatozoa from herrings consists as to three-quarters of nucleic acid and one-quarter of clupeine. The two compounds are united through the free amino-groups of the arginyl groups of the protamine.   E. F. A.

The Biochemistry of the Female Genitalia. I. The Lipins (Lipoids) of the Ovary and Corpus Luteum of the Pregnant and Non-pregnant Cow. JACOB ROSENBLOOM (*J. Biol. Chem.*, 1913, 13, 511—512).—Data are presented showing the percentages of fat, fatty acids, cholesterol, and lipoids in the ovary and corpus luteum of the cow. No increase in these occurs during pregnancy.   W. D. H.

The Sulphatide of the Brain. PHŒBUS A. LEVENE (*J. Biol. Chem.*, 1913, 13, 463—464).—The lipoid of the brain (ox), which contains sulphur, was isolated from the phosphatides; the method is not described. Elementary analyses are given which differ considerably from those of both Thudichum and W. Koch.   W. D. H.

The Influence of Quantity and Concentration of Poisons of the Digitalis Group on the Frog's Heart ARNOLD HOLSTE (*Arch. expt. Path. Pharm.*, 1912, 70, 435—438).—The experiments recorded show the importance of concentration as a factor.
          W. D. H.

Systole and Diastole of the Heart Under the Influence of Digitalin. ARNOLD HOLSTE (*Arch. expt. Path. Pharm.*, 1912, 70, 439—446).—It is stated that digitalin applied internally to the heart produces systolic standstill, and to the exterior, diastolic standstill. This has been explained by supposing that the outer layers of the cardiac muscle respond differently to the drug from the internal layers. The present experiments show that the medium used is a factor. Fluids which contain blood, or Albanese's solution, always produce stoppage in systole, whereas if Ringer's solution is employed as the medium, the stoppage is diastolic.   W. D. H.

Replacement of Urea in Artificial Solutions for the Isolated Heart of Selachians. R. BOMPIANI (*Atti R. Accad. Lincei*, 1912, [v], **21**, ii, 667—672).—Solutions containing urea, when administered by perfusion or otherwise, increase the time of survival of isolated hearts. The author's experiments on isolated hearts of *Torpedo ocellata* and *Scyllium* show that no substance will quite replace urea in this respect, but the derivatives of urea favour the survival more than other substances (methylcarbamide, survival 480 minutes; urea, survival 600 minutes), but the action is less marked the more distantly the substances are related to urea. Neither glycerol, acetone and urethane (although they are soluble in lipoids), nor the amino-acids, glycine, asparagine, aspartic acid and its salts keep the isolated hearts alive. R. V. S.

Toxicological Investigations on Bio-electric Currents. III. Comparative Toxicological Specificity of the Chemical Alteration Current, and Comparative Physiology and Toxicology of the Heart of Helix pomatia. C. LOVATT EVANS (*Zeitsch. Biol.*, 1912, **59**, 397—414).—Henze and Hermann have shown that skeletal and heart muscle of the frog responds specifically to poisons, and that the electrical changes run parallel to such action. This thesis is supported by the present investigations on the snail's heart, which is recommended as a convenient object for such work. Its electrogram is very simple, showing a pure diphasic effect, which corresponds with the single peristaltic wave which travels over it. Carbon dioxide acts tonically on it. The heart of the snail is sensitive to potassium, and very resistant to calcium; muscarine has the usual effect, but this is not antagonised by atropine. Antiarin has no action, but strophanthin and saponin are active. W. D. H.

Tolerance for Sugar in the Pig. ANTON J. CARLSON and F. M. DRENNAN (*J. Biol. Chem.*, 1913, **13**, 465—468).—Minkowski stated that the removal of the pancreas in the pig did not result in as severe diabetes as in other animals. In the present experiments, fatal diabetes did occur, but it was of slow onset. The pig has a lower tolerance for dextrose than any species so far studied; that is, it becomes glycosuric when quite small amounts of sugar are given by the mouth.

Occurrence of Metals in the Human Liver. LEOPOLD VAN ITALLIE and J. J. VAN ECK (*Pharm. Weekblad*, 1912, **49**, 1157—1163.* Compare Lehmann, A., 1896, ii, 486).—An investigation of the corpses of persons of various ages indicates that arsenic is not a normal constituent of the human liver, but that copper and zinc are always present, the proportion of copper being greater during the foetal period than in later life. Otherwise, age, sex, occupation, and place of residence appear to have no influence on the proportion of copper and zinc. The values given by Lehmann for the amount of copper present are appreciably too low. A. J. W.

* and *Arch. Pharm.*, 1913, **251**, 50—55.

The Influence of Iodine on Autolysis. M. KASCHIWABARA (*Zeitsch. physiol. Chem.*, 1912, **82**, 425—438).—Contrary to the statements of Kepınov (A., 1912, ii, 69), autolysis does not occur in a medium containing 0·5% of sodium hydroxide ; what does occur there is hydrolysis produced by the alkali ; this is only slightly increased by the presence of iodine. In alkali-free mixtures, iodine increases autolysis only in a slight degree. In rabbits which had received an intravenous injection of Lugol's solution, autolysis of the liver is also slightly accelerated, but even the fresh liver of such animals show an increase in non-coagulable nitrogen.   W. D. H.

The Catalytic Action of Iron Salts on the Autolysis of the Liver. LUIGI POLLINI (*Biochem. Zeitsch.*, 1912, **47**, 396—404).— Small and large quantities of ferric sulphate and ferric chloride increase the total nitrogen and the nitrogen of the monoamino-acids, proteoses and purine substances in the autolysis products when calves' liver is allowed to autolyse in the presence of these salts. Small quantities of iron citrate exert a weak inhibitory action, whereas larger quantities exert an accelerating action ; still larger quantities inhibit the autolysis as regards total nitrogen and the nitrogen of amino-acids. The proteose nitrogen, on the other hand, continually increases with increasing amounts of the iron salt. Very small quantities of iron lactate accelerate the autolysis, but progressingly larger quantities exert a progressive amount of inhibition.   S. B. S.

The Physiology of the Thyroid Glands. The Content of Phosphorus, Nitrogen, and Lipoids in the Organs of Thyroidectomised Animals. A. S. JUSCHTSCHENKO (*Biochem. Zeitsch*, 1913, **48**, 64—85).—The experiments were carried out with young dogs, of which a certain number were submitted to thyroidectomy, and an equal number from the same litter were used as controls. It was found that the organic and total phosphorus was diminished in the thyroidectomised animals in the brain, heart, and spleen, whereas the inorganic phosphorus is increased. In the liver, the changes were similar, but in the muscles the results were indefinite. In the kidneys the amount of phosphorus in all forms, and especially the inorganic, was increased. The nitrogen in the majority of the organs of thyroidectomised animals was increased ; this statement does not apply, however, to the kidneys and the serum. In animals with hyperthyroidism the total and organic phosphorus in brain, muscles, and heart are diminished ; in the liver, kidneys, spleen, and serum, on the other hand, they are increased. In most organs, the nitrogen content is diminished. In thyroidectomised animals, the lipoids, and all the fractions of the same, are diminished in quantity in the brain, liver, and muscles, whereas they are in increased amount in the serum. In other organs, the lipoid quantity is also less than in the normal. In hyperthyroidism, the content of lipoid in the serum is diminished, whereas no very definite results were obtained by the examination of other organs. The ratios of the nitrogen to phosphorus in various fractions of the lipoids in thyroidectomised animals, and in cases of hyperthyroidism, were also investigated. Thyroidectomy also

causes increase in the content of the purine substances of the organs. Complete thyroidectomy causes at first an increase in the phosphorus : nitrogen ratio in the urine, followed by a diminution of this ratio ; the quantity of urea diminishes. The quantity of ammonia at first falls, and then rises ; there is apparently an increase in amino-acids and purine bases; the creatinine, on the other hand, diminishes.

S. B. S.

Seasonal Variation in the Iodine Content of the Thyroid Gland. ATHERTON SEIDELL and FREDERIC FENGER (*J. Biol. Chem.*, 1913, 13, 517—526).—In sheep, ox, and pig there is about three times as much iodine in the thyroid between June and November as between December and May. In the sheep and ox (but not in the pig) the gland is larger during the latter months.   W. D. H.

Enzyme Synthesis. IV. Lactase of the Mammary Gland. HAROLD C. BRADLEY (*J. Biol. Chem.*, 1913, 13, 431—440).—These experiments give no support at all to the theory of enzyme syntheses in tissues, for lactase was never found in the mammary gland, or in the milk.   W. D. H.

Muscle Chemistry. IV. The Extractive Nitrogen and the Free Amino-nitrogen, Titratable by Formaldehyde in the Musculature of Different Animals. GIUSEPPE BUGLIA and A. COSTANTINO (*Zeitsch. physiol. Chem.*, 1912, 82, 439—462. Compare A., 1912, ii, 1077, 1078).—A large number of details of the distribution of nitrogen in muscle in many animals are given, and great variations are met with in both vertebrate and invertebrate animals ; but no constant and characteristic features distinguish the musculature of the various animal groups.   W. D. H.

Muscle Chemistry. V. Purine Bases of the Smooth Muscle of the Higher Animals. GIUSEPPE BUGLIA and A. COSTANTINO (*Zeitsch. physiol. Chem.*, 1913, 83, 45—49).—The purine bases of the smooth muscle of the ox (retractor penis) consist of oxypurines; xanthine, probably preformed, exceeds hypoxanthine in amount, which is the opposite to that found in striated muscle.   W. D. H.

The Formation of Lactic Acid in the Antiseptic Autolysis of Organs. NICOLAUS SOBOLEV (*Biochem. Zeitsch.*, 1912, 47, 367—373).—In estimating the lactic acid produced by autolysis of the organs, account was taken of the amount of acid carried down by the coagulum when the autolysis product was heated, the amount withdrawn from the solution in this process being estimated by Mondschein's method. At the ordinary temperature, less lactic acid is formed on autolysis than at 40°. Most organs show a maximum production at this temperature after about thirty-three days, after which the amount diminishes. The maximum production took place in the liver, followed by the spleen, heart, muscles, and kidneys in diminishing order.

S. B. S.

Enzyme Synthesis. II. Diastase and Glycogen of Animal Tissues. HAROLD C. BRADLEY and E. KELLERSBERGER (*J. Biol. Chem.*, 1913, 13, 419—424).—Tissues rich in diastase may or may not

contain glycogen, and what is more significant from the point of view of the enzyme-synthesis theory, tissues rich in glycogen may or may not contain diastase.   W. D. H.

Enzyme Synthesis. I. Lipase and Fat of Animal Tissues. HAROLD C. BRADLEY (*J. Biol. Chem.*, 1913, 13, 407—418).—No broad correlation exists between the amounts of fat and lipase in tissues. Some of the tissues which actively produce fat may, in fact, contain relatively little lipase, and tissues which are poor in fat may contain a good deal. The experiments afford no support to the theory of enzyme synthesis.   W. D. H.

The Influence of the Lipoids on the Action of Oxydases. HORACE M. VERNON (*Biochem. Zeitsch.*, 1912, 47, 374—395).—If minced tissue is left for half an hour in varying strengths of solu· tions of a narcotic up to a certain concentration, the narcotic is then washed out and the oxidising power of the tissue tested by a-naphthol and p-phenylenediamine, it will be found that the oxidising power is either uninfluenced or increased. In higher concentrations the oxydase is injured. Concentrations, twice or three times as large as those necessary to produce initial action, destroy the oxydase completely; thus, for example, acetone first in $4M$-solution attacks the oxydase, which is destroyed completely in $7M$-solution. These limits were investigated in several cases. The concentrations of monohydroxy-alcohols, which degrade the oxidative capacity 50%, are about twenty times stronger than those necessary to narcotise tadpoles, whereas in the case of fatty esters and methylurethane, they are twelve times stronger. In poisons other than lipoid-soluble substances, such as formaldehyde, the range of action is larger; thus, 1330 times as much formaldehyde is necessary completely to destroy the oxydase as is necessary to produce the initial action. In the case of the typical narcotic, paracetaldehyde, the relationship of these quantities is only 1·8:1. The range of action of ammonia is even greater than that of formaldehyde. Concentrations of narcotics which cause the initial effects are only a little greater than those necessary to hæmolyse red blood-corpuscles. The author draws the conclusion that the action of the indophenol oxydase is dependent on the lipoid, or perhaps the lipoid membrane, which, he considers, holds together the tissue oxydase and the peroxydase, which are thereby enabled to exert their joint action.   S. B. S.

The Ferments of the Purine Group. ARTHUR SCHULZ (*Biochem. Zeitsch.*, 1913, 48, 86—119).—In estimating uric acid in organs, formaldehyde up to 2% was added to the solution, after coagulating the proteins in the presence of sodium chloride and acetic acid. The effect of this addition is to render the uric acid more soluble. It was then estimated in the filtrate in the ordinary way by the Schmid-Krüger method. For investigating the uricolytic ferment, dried organ powders were generally employed. It was found that radium emanations of an activity of 5—10 Mache units per c.c were without any recognisable influence on the uricolytic action of

dogs' liver or ox-kidneys. Radium emanations increase the activity of the uricolytic ferments of ox-spleen, both as regards the formation of uric acid from added purine bases and from those produced by autolysis. The increased amount of uric acid formed varied, under the conditions of the experiments, from 10 to 20%. There was an increase, in the case of autolysis, in the activity of the proteolytic ferments, as shown by the increase in the nitrogen of the uncoagulable substances. This amount was, however, relatively less than the increased amount of uric acid formed. The uricolytic ferments of ox-kidneys are totally inhibited in action by fresh pulp of ox-spleen. Ox-kidney powder can inhibit the purine deamidases and the oxydases of the ox-spleen, but not the autolytic uric acid formation by the same organ. The author did not succeed in producing anti-uricolytic ferments by immunisation of rabbits by organs containing uricolytic ferments.   S. B. S.

Creatine, Creatinine, and Monoamino-acids in Certain Fishes, Mollusca, and Crustacea. Y. OKUDA (*J. Coll. Agric. Imp. Univ. Tokyo*, 1912, 5, 25—31).—Seven varieties of fishes were found to contain from 0·421 to 0·754% of creatine and 0·070 to 0·660% of creatinine. Mollusca contained only traces of these compounds, and crustacea only traces, if any at all.

All the marine animals examined contained much more nitrogen as organic bases than in the form of monoamino-acids, the amount of which is usually very small in fish, but somewhat higher in lobsters and cuttle-fish.

Most of the proteins are soluble in dilute alkali solution, and a good deal is soluble in 10% sodium chloride.   N. H. J. M.

The Occurrence of Glycogen in Sea-Molluscs (Especially Cephalopods and Aplysiæ). EMIL STARKENSTEIN and MARTIN HENZE (*Zeitsch. physiol. Chem.*, 1912, 82, 417—424).—*Cephalopods* and *Aplysiae* have been stated to be free from glycogen. This is not so ; they contain abundance of it. Glycogen is the same substance whether it is derived from vertebrates or invertebrates.   W. D. H.

Carbon Metabolism. The Labile and Stable Carbon of the Urine. ENRICO REALE (*Biochem. Zeitsch.*, 1912, 47, 355—366).—The carbon of the urine was estimated by a wet-oxidation process, by oxidation with chromic acid and sulphuric acid, for which a modification of the apparatus of Desgrez (which is figured in the text) was employed. It was found that only about half the carbon in the urine exists in the form of urea. It was also found that a part of the carbon is readily oxidised to carbon dioxide in the presence of hydrogen peroxide when manganese peroxide is used as a catalyst. This is designated by the author "labile carbon," whereas the carbon which is not so oxidised is called "stable carbon." Full experimental details for the estimation of carbon in these two forms are given.   S. B. S.

The Intensity of Urinary Acidity in Normal and Pathological Conditions. LAWRENCE J. HENDERSON and WALTER W. PALMER (*J. Biol. Chem.*, 1913, 13, 393—405).—Normal urine ranges

from a concentration of ionised hydrogen of about 4·82 to 7·45 ; the mean value is 6·00. Pathological conditions occasionally cause a greater acidity, but never unusual alkalinity. No attempt is made at present to generalise, except in cises of cardio-renal disease, where the high mean acidity may indicate a form of acidosis.   W. D. H.

The Origin and Destiny of Cholesterol in the Animal Organism. X. The Excretion of Cholesterol in Man when Fed on Various Diets. GEORGE W. ELLIS and JOHN A. GARDNER (*Proc. Roy. Soc.*, 1912, *B*, 86, 13—18. See A., 1912, ii, 275, 958).— In man as in other animals, the excretion of cholesterol in the fæces can be accounted for by that taken in with the food, provided the body-weight remains constant. If, however, a rapid loss of weight takes place, as in illness, the output of cholesterol exceeds the intake.

Further work will be necessary before this view can be regarded as established.   W. D. H.

Influence of Alkaline Salts in the Elimination of Urinary Ammonia by Normal Dogs. HENRI LABBÉ (*Compt. rend.*, 1912, 155, 1620—1622. Compare A., 1911, ii, 220).—With dogs in a state of nitrogenous equilibrium on a meat diet, the simultaneous ingestion of ammonium salts and excess of sodium carbonate produces a slightly less elevated elimination of volatile .basic nitrogen than when the ammonium salts are ingested alone. The difference is more marked with ammonium carbonate than with ammonium chloride. A large excess of sodium carbonate (about 2 grams per kilo. of body-weight), which provoked great thirst and marked polyuria, did not cause all the basic volatile nitrogen to disappear.   W. G.

The Relationship between the Nitrogen of the Amino-acids and Total Nitrogen in Urine under Various Normal and Pathological Conditions. ERNESTO SIGNORELLI (*Biochem. Zeitsch.*, 1912, 42, 482—506).—The experiments were carried out on dogs. The percentage of the amino-acid nitrogen (of the total nitrogen) varied in starvation between 1·09 and 1·30. It showed no very marked increase when oxidation was increased by the animals breathing pure oxygen. The value showed no marked differences when the proteins ingested by the animals were varied (caseinogen, gelatin, gluten, and zein). The percentage was only slightly increased (1·37—2·51) when the hydrolysis products of these proteins were administered subcutaneously. When azoturia was produced by fever, etc., the percentage still remained normal. In phosphorus poisoning, when the functions of the liver were disturbed, it rose to 3·66. Two hypotheses are advanced to account for the approximate constancy of the percentage : (*a*) that in all proteins there is a part which is not readily oxidised, and (*b*) that in the enzyme reaction producing deamidisation there is an equilibrium point at which part of the substance remains unacted on.   S. B. S.

The Fat Content of Normal and Pathological Urine. KŌZŌ SAKAGUCHI (*Biochem. Zeitsch.*, 1913, 48, 1—34).—The method

employed for estimating fat was that of Kakiuchi (A., 1910, ii, 549). The amount excreted in a normal adult urine is 0·0085 gram in twenty-four hours, which can be increased to 0·0341 gram after diets containing very large amounts of fat. Out of three cases of nephritis investigated, in only one was the fat excretion regularly above normal. In diabetes, tuberculosis of the lungs, jaundice, and cirrhosis of the liver, the excretion was normal. No extra excretion could be detected in cases of fractures of bones or re-section, and in this respect the results of the author differ from those obtained by earlier investigators.　　　　　　　　　　　　　　　　　　　　　S. B. S.

Urobilin. III. and IV. G. FROMHOLDT and N. NERSESSOV (*Chem. Zentr.*, 1912, ii, 1678; from *Zeitsch., expt. Path. Ther.*, 1912, 11, 400—407).—The administration of fresh bile leads to the appearance of urobilin in the urine, but this does not occur when pure bilirubin or bile extracted with ether is given. A method of extracting urobilin from blood is described. After preliminary extraction with alcohol and filtration, it is acidified and extracted with amyl alcohol, in which solvent the pigment is detected spectroscopically. If urobilin is absent from the urine, it is also absent from the blood, but when present in the urine it is usually present in the blood as well.　　　W. D. H.

Blood Destruction, Bile and Urobilin. The Formation of Bile Pigment in Blood. III. THEODOR BRUGSCH and KARL RETZLAFF (*Chem. Zentr.*, 1912, ii, 1678—1679; from *Zeitsch. expt. Path. Ther.*, 1912, 11, 508—525).—Estimations of urobilin in urine and fæces in various cases of liver disease lead to the conclusion that urobilinuria is the clinical expression for a series of substances related to blood and bile pigment. Hæmatogenous or extra-hepatic urobilin-uria occurs after extravasation of blood in the tissues; its other cause is usually hepatic insufficiency. If the bile enters the intestine, its pigment is converted into urobilin and re-absorbed; the liver then manifests its insufficiency by being incapable of re-synthesising bile-pigment from the urobilin, which therefore passes into the blood and urine. Urobilin in urine and fæces was estimated by making alkaline with ammonium carbonate and letting the mixture remain at 37° for two days. It was then extracted with light petroleum until Ehrlich's reaction was negative, then acidified with tartaric acid, and extracted with ether. A measured quantity of the ethereal solution was mixed with an ethereal solution of *p*-dimethylaminobenzaldehyde and a few drops of hydrochloric acid in absolute alcohol, and examined chromo-photometrically.　　　　　　　　　　　　　　　　　　　W. D. H.

The Protective and Curative Properties of Certain Food-stuffs against Polyneuritis Induced in Birds by a Diet of Polished Rice. EVELYN A. COOPER (*J. Hygiene*, 1913, 12, 436—462).—In pigeons weighing 350 grams, as much as 20 grams of raw beef are necessary daily to prevent polyneuritis; the anti-neuritic value of beef is therefore low. Heart muscle is better, and sheep's brain about twice as efficient as beef. Brain is specially efficient in preventing loss of body-weight which ensues when polished

rice is given. Fish is very inefficient in both directions. Egg-yolk, even if boiled, is the most efficient of all the animal foods examined : 3 grams daily is enough. Dried lentils and unhusked barley are about equal to egg-yolk. Yeast is the most efficient of all foods. The antineuritic and weight-maintaining action of the various foods differs. The weight-maintaining constituents are not protein, fatty or lipoidal. W. D. H.

Congenital Family Steatorrhœa. ARCHIBALD E. GARROD and W. H. HURTLEY (*Quart. J. Med.*, 1913, 6, 242—258).—The details of a curious case of an inborn metabolic error are recorded. The boy (aet. 8) has been subject since infancy to the passage of liquid fat from the bowel ; one cooling it solidifies ; another brother who died in infancy had the same defect. Health was apparently unaffected ; the stools contained 25% of the fat in the food ; with an intake of 177 grams of fat only 4% was split ; this figure rises when the intake is less, but even then it is not absorbed. Sodium glycocholate and various pancreatic preparations increased fat-splitting, but not the absorption ; indeed, the latter aggravated the condition. W. D. H.

The Mechanism of the Action of Silver Haloids. OSKAR GROS (*Arch. expt. Path. Pharm*, 1912, 70, 375—406).— Colloidal silver chloride and iodide intravenously injected in rabbits are strongly toxic, and the chloride is more so, even though the concentration of silver ions is the same in both cases. This is considered to be due to the formation of a complex of the silver salt and the chlorides of the blood plasma which is more readily carried to the tissue cells. Sodium iodide, which is non-toxic if given simultaneously, increases the poisonous action of silver iodide. This is explained on similar lines. In vitro, both salts are hæmolytic, and again the chloride is more effective, but here sodium iodide does not increase the action of silver iodide. W. D. H.

A Physiological Series of Cations. N. K. KOLTZOV (*Pflüger's Archiv*, 1912, 149, 327—363).—The observations were made on the effect of salt solutions on the vitality and contractility of a marine infusorian (*Zoothamnium alternans*). They follow in the main the work of Overton and others who have bestowed attention to osmotic phenomena and the rôle of the plasmatic membrane of cells. If chlorides are employed throughout, the cations are arranged in the following order : K, Rb, Na, Os, NH$_4$, Li, Sr, Mg, and Ca. Each member of the series lowers the surface tension of plasma-water less than the succeeding one, and toxicity runs parallel with the adsorption of the cations. W. D. H.

Temporary Fixation and Mode of Elimination of Manganese in the Rabbit. GABRIEL BERTRAND and FLORENTIN MEDIGRECEANU (*Compt. rend*, 1912, 155, 1556—1559).—Four rabbits received repeated subcutaneous injections of manganous sulphate in varying doses, and the effect on their weight and length of life was noted

Even with minute doses there was a marked loss in weight, and three injections of 5 mg. of manganese per kilo. of body-weight, at intervals of twenty-four hours, caused the death of the rabbit. The amount of manganese in the various organs of the four rabbits and of an uninjected rabbit was determined, and the results show that manganese, when subcutaneously injected, is rapidly diffused throughout the body, and all the tissues, including the nervous tissue, become temporarily impregnated. It is readily eliminated through the liver, bile, and mucus of the alimentary canal, and a small quantity is excreted in the urine. W. G.

The Action of Certain Substances of the Chloroform Group on the Vestibular Eye-Reflex. J. ROTHFELD (*Pflüger's Archiv*, 1913, 149, 435—446).—Nystagmus (vestibular eye-reflex) disappears under the influence of narcotics ; first vertical, then rotatory, and finally horizontal nystagmus. As anæsthesia passes off, they reappear in the reverse order. The substances employed in the research were chloroform, ether, chloral hydrate, and paracetaldehyde. The differences in detail between these four substances are treated at length. W. D. H.

The Fixation of Digitoxin (Merck) in the Organism of the Rabbit after Intravenous Injection. Comparative Experiments with Strophantin-*g*. CAMILL LHOTÁK VON LHOTA (*Biochem. Zeutsch.*, 1913, 48, 144—154).—If digitoxin is injected intravenously into rabbits, it disappears almost immediately from the blood (as ascertained by tests on the frog's heart), even when ten times the lethal dose is employed and the conditions of the animal are favourable. These conditions are, that the heart should be active, and the functions of the blood-vessels intact. If these are interfered with in any way (by narcosis, etc.), digitoxin can be detected in the blood when only twice the lethal dose has been employed. After injection of ten lethal doses, the digitoxin can be detected in all organs, especially the heart and liver. The greater the length of the circulatory system the drug must travel from the point of injection to reach the heart, the greater is the dose necessary to produce the specific action, This fact indicates that the drug is fixed by the vessels as well as the heart, and was demonstrated by experiments on animals with crossed circulatory systems. The drug can also be detected chemically at the point of application. Intravenously injected strophantin-*g* only disappears immediately from the blood in small quantities. S. B. S.

The Fate of Proline in the Animal Body. HENRY D. DAKIN (*J. Biol. Chem.*, 1913, 13, 513—516).—When proline is added to blood, and the mixture perfused through the surviving liver of a dog, there is no increase in the formation of acetoacetic acid ; but in the glycosuric animal it causes a marked increase in the sugar output. The formation of dextrose from proline involves the disruption of the ring. Glutamic acid also yields sugar (Lusk) ; so also do arginine and ornithine. The close structural relationship of glutamic acid, ornithine, and proline is shown graphically, W. D. H.

The Results of Poisoning with Adrenaline, Histamine, Pituitrin and Peptone in Relation to Anaphylaxis and the Vegetative Nervous System. ALFRED FRÖHLICH and ERNST P. PICK (*Arch. expt. Path. Pharm.*, 1912, '71, 23—61).—The substances mentioned in the title greatly lessen or abolish the excitability of the autonomic nervous system, both to faradic stimuli and to drugs. The same occurs in "peptone immunity" and in anti-anaphylaxis. As both these phenomena soon disappear, they are separable and reversible. The effect of the poisons is a selective one on the nerve endings. A considerable amount of the work recorded was performed on the uterus, and it was then found that after the use of histamine, adrenaline and pilocarpine had no effect, and pituitrin very little. After treatment with tyramine, pituitrin, histamine and adrenaline act normally; after treatment with pituitrin, adrenaline acts normally; after peptone, pituitrin, tyramine and adrenaline have no action. Barium chloride locally applied to the uterus causes contraction of the uterus after it has been rendered inexcitable by histamine, tyramine, or peptone.   W. D. H.

The Pharmacological Action of *p*-Hydroxyphenylethylamine. A. BICKEL and MICH. PAVLOV (*Biochem. Zeitsch*, 1912, 47, 345—354).—This substance, which can be isolated from ergot, shows the following actions. When 1—2 c.c. of a 0·5% solution are injected into rabbits or dogs of medium size, the arterial blood-pressure, after a short-lasting fall, rises, remains high for two or three minutes, and then sinks to normal. This is due to a contraction of the capillaries, with a consequent diminution of the amount of blood in the veins, which was detected by the measurement of the blood-flow in the venous system. As a further consequence there is a diminution of volume of organs which have a well-developed venous supply. This fact was demonstrated directly by the measurement of changes produced in the kidneys after the injection of the drug, and indirectly by the changes in the intestinal volume after injection of extracts of *Secale cornutum*.   S. B. S.

Action of Scopolamine (Hyoscine). ARTHUR R. CUSHNY (*Arch. expt. Path. Pharm.*, 1912, 70, 433—434).—A criticism on the work of Hug (A., 1912, ii, 790), who finds, like the author, that *l*- and *i*-hyoscine differ in their action on nerves. The quantitative differences between the two workers are explained as due to differences in the methods used.   W. D. H.

The Method of Action of Quinine. J. MOLDOVAN (*Biochem. Zeitsch.*, 1912, 47, 421—446).—The action on *Colpidia* is to cause a change in the state of the colloids of the protoplasm, leading to a separation of droplets of lipoid character, and producing a change in the osmotic relationship of the protoplasm to its surroundings; afterwards the nucleus and motility of the cell are injured, and finally death results. The cause of death is the stoppage of oxygen respiration. In the case of trypanosomes, the action is similar, but the separation of droplets is less marked, owing to the smaller content of lipoids. Similar actions were also observed on plant cells. There is a con-

siderable difference of behaviour in the individual cells as regards the resistance to the action of quinine, which depends on the energy of the oxygen respirations; older cells appear to be more resistant than young cells. The combined effect of two toxins on the cells is not the sum of the effect of each individual toxin, but depends, amongst other factors, on the relative concentrations of the two. In rabbits and guinea-pigs, the action of quinine is to diminish the oxidative processes, especially in the brain. This fact was demonstrated by various methods of intra vitam staining (according to the method of Ehrlich, etc.). The quinine in influencing the oxidative process does not effect the oxygen taken up, but acts as an anticatalyst. In view of the first action of quinine on cells, in causing the separation of the lipoids, it can act as a narcotic or local anæsthetic. To produce general narcosis, however, the required dose is so high that it acts deleteriously on the respiration, and it cannot therefore be used in practice for this purpose. S. B. S.

Influence of the Constitution of Purine Derivatives on their Action with Respect to Arterial Pressure. ALEXANDRE DESGREZ and DORLÉANS (*Compt. rend.*, 1913, 156, 93—94).—Whilst guanine on intravenous injection into a rabbit causes a diminution in the arterial blood pressure (compare A., 1912, ii, 585), hypoxanthine, xanthine, and uric acid exert a hypertensive action. The increase in pressure, whilst slight for hypoxanthine, is greater for xanthine and still greater for uric acid. From this it appears that the guanine owes its hypotensive action to the presence of the amino-group in its molecule. The action of these substances, especially of uric acid, is of interest in the pathogenesis of arthritic diseases, in which Bouchard has shown that there is marked arterial hypertension. W. G.

The Biological Action of Certain Protein Products Introduced Parenterally. ALFRED SCHITTENHELM and WOLFGANG WEICHARDT (*Chem. Zentr.*, 1912, ii, 1680; from *Zeitsch. Immunitätsforsch. exper. Ther.*, 1912, 14, 609—630).—The simple and conjugated proteins introduced into the blood stream are relatively innocuous; but the protein constituents of conjugated proteins (globin, histone, protamine) cause great depression of blood pressure, affect breathing and temperature, and lead in quite small doses to death. This has been attributed to the high percentage of diamino-acids they contain, but this cannot be the case because histone is poor in such acids, and certain kyrines rich in them are not toxic. Such proteins when united to nucleic acid or to hæmochromogen in the case of globin lose their toxicity. Toxic symptoms which occur when hæmolysis takes place in the blood stream may be due to the liberation of the poisonous globin (proteinogenous cachexia). W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

The Relation of Concentration of Food supply to the Generation Time of Bacteria. W. J. PENFOLD and (Mrs.) DOROTHY NORRIS (*J. Hygiene*, 1913, **12**, 527—531).—The generation time of *B. typhosus* in 1% peptone at 37° is forty minutes. If the peptone solution is less than 0·2% in strength the generation time is inversely proportional to the concentration. The addition of 0·17% of dextrose to a medium containing only 0·1% of peptone lowers the generation time by 50%; with 1% peptone this effect is less marked.

W. D. H.

The Bactericidal Properties of Blood Serum. I. The Reaction Velocity of the Germicidal Action of Normal Rabbit Serum on the Bacillus coli commune, and the Influence of Temperature Thereon. (Miss) HARRIETTE CHICK (*J. Hygiene*, 1913, **12**, 414—535).—The action *in vitro* of rabbit serum on *B. coli* consists of several phases, the duration of which is inversely proportional to temperature. Its germicidal action follows the logarithmic law, and so falls into line with other cases of disinfection. Its temperature-coefficient is low (2·84 to 1·93).

W. D. H.

Chemical Action of Bacillus cloacæ (Jordan) on Citric and Malic Acids. JAMES THOMPSON (*Proc. Roy. Soc.*, 1912, *B*, **86**, 1—12).—The respiratory coefficient for malic and citric acids was determined and found to be 1·63 and 2·35—3·2 respectively.

In the presence of oxygen, *B. cloacæ* decomposes malic acid with the production of carbon dioxide, acetic acid, succinic acid, a small quantity of fatty substance, and traces of alcohol. It is suggested that the action probably goes on in two ways: an oxidation of acid to carbon dioxide and acetic acid by atmospheric oxygen, and an oxidation accompanied by reduction of a portion of the acid to succinic acid. The organism does not attack malic acid in the absence of oxygen.

The products resulting from the decomposition of citric acid are the same as from malic acid. Under aerobic conditions the amount of acetic acid is greater, whilst anaerobic conditions lead to an increase in the production of acetic and formic acids. Acetylmethylcarbinol is not formed by the action of *B. cloacæ* on malic or citric acids.

H. B. H.

The Degradation of Polypeptides by Bacteria. II. The Action of the Non-liquefying Organisms TAKAOKI SASAKI (*Biochem. Zeitsch.*, 1912, **42**, 462—471. Compare A., 1912, ii, 669).—Organisms which are incapable of liquefying gelatin contain nevertheless an erepsin-like ferment capable of hydrolysing glycyl-glycine and glycyl-*l*-tyrosine. Relatively large quantities of tyrosine could be isolated as a result of the action. This action was demonstrated

by typhus and various strains of paratyphus bacilli, various bacilli of dysentery, bacilli of mouse typhus, chicken cholera, a id *Micrococcus*

S. B. S.

The Degradation of Polypeptides by Bacteria. III. The Action of Liquefying Organisms. TAKAOKI SASAKI (*Biochem. Zeitsch.*, 1912, **47**, 472—481).—Glycyl-glycine and glycyl-*l*-tyrosine were hydrolysed (in Fränkel's solution) by the following strains. Bacilli of splenic fever, *Staphylococcus pyogenes aureus, citreus,* and *albus, B. subtilis, B. proteus vulgaris, B. pyocyaneus, B. prodigiosus,* cholera vibrio, and the vibrios of Metchnikov and Dunbar and the water vibrio.

S. B. S.

Production of Citric Acid from Glycerol by Fungi. CARL WEHMER (*Chem. Zeit.*, 1913, **37**, 38—39. Compare A., 1893, ii, 591; 1909, ii, 602; 1910, ii, 60, 61).—When two species of *Citromyces* were grown in nutrient solution containing ammonium nitrate, potassium phosphate, magnesium sulphate, calcium carbonate, and glycerol (3—20%), large quantities of citric acid were produced. In the absence of calcium carbonate no such accumulation occurs, and it is assumed that, in the absence of any neutralisable base, any citric acid formed is destroyed immediately by the fungi. Similar growth takes place when the glycerol is replaced by sucrose, lactose, mannitol, xylose or arabinose. Sucrose is inverted, and reducing substances are formed in cultures supplied with glycerol. The author discusses the mechanism of citric acid formation from glycerol, and contests the view advanced by Mazé, that acid is only produced when there is a deficiency of nitrogen, or that it is in any way due to a lack of iron or zinc.

H. B. H.

Action of Hydrogen Ions, Boric Acid, Copper, Manganese, Zinc, and Rubidium on the Metabolism of Aspergillus niger. H. J. WATERMAN (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, **15**, 753—764).—In investigating the culture conditions of *Aspergillus niger* it is not sufficient to merely ascertain the dry weight produced, as was done by Raulin and others. Spore formation, for instance, produces differences in composition. It is, therefore, desirable to determine the changes of the plastic equivalent, or of the assimilation quotient, several times during development.

Addition of 2·35 c.c. of *N*-sulphuric acid to 100 c.c. of culture solution and of 0·5% of boric acid has very slight effect on the plastic equivalent of the carbon.

A high weight of mycelium is not always a favourable indication. It was found that certain concentrations of copper sulphate, zinc chloride and sulphate considerably increase the plastic equivalent of the carbon, whilst the increase in the weight of mould is proportional to the retarded spore production. Very dilute zinc solutions have no effect; copper salts, in all dilutions, counteract spore formation. Minimal quantities of manganese do not alter the plastic equivalent of the carbon, but only affect the rate of metabolism. The amounts of dry matter found by Bertrand should be considered as values indicating the velocity of the process.

When potassium is replaced by rubidium, spore formation is checked, the weight of mould increased, whilst the metabolism of the carbon remains the same.   N. H. J. M.

Influence of Zinc, Magnesium, Calcium, Potassium, and Sodium Salts on the Growth of Aspergillus niger. J. BUROM-SKI (*Centr. Bakt. Par.*, 1912, ii, 36, 54—66. Compare A., 1908, ii, 124 ; 1911, ii, 222, 421, 664 ; 1912, ii, 377, 861).—The fungus was grown in a medium consisting of ammonium sulphate or nitrate 1%, sucrose 5%, magnesium sulphate 0·25%, monopotassium phosphate 0·5%, traces of ferrous sulphate, and distilled water. The addition of zinc sulphate in the proportion of 0·001—0·1% led to an increase in the respiratory coefficient (car bon dioxide crop) : that of the control and treated cultures respectively being 1·8 and 2·4 at 30°, and 2·8 and 3·5 at 20°. The addition of calcium sulphate to magnesium-free medium decreased the growth of the organism ; 0·25% magnesium sulphate to magnesium-free medium increased the crop very greatly, whilst calcium and magnesium sulphates increased the growth still more. The presence of calcium salts prevents the accumulation of oxalates in the cultures. Magnesium sulphate may be beneficially increased to 0·5%, although fructification begins to be affected at this concentration. Sodium salts proved to be without value, but increasing amounts of potassium salts caused corresponding increases of growth. Magnesium and potassium salts therefore, not only serve as nutrients, but also exercise a stimulative action.   H. B. H.

Enzymatic Nature of Uric Acid and Hippuric Acid Ferment-ation. ALEXANDER KOSSOWICZ (*Chem. Zentr.*, 1912, ii, 1300, 1482 ; from *Zeitsch. Gährungsphysiol*, 1, 121—123, 317—319. Compare this vol., i, 146).—Filtered solutions from cultures of *Aspergillus niger*, *Mucor Boidin*, *Phytophthora infestans*, *Isaria farinosa*, and *Botrytis bassiana*, in which urea was present as only source of nitrogen, liberated ammonia from uric and hippuric acid, and from the latter, benzoic acid as well. A filtrate from *Cladosporium herbarum* only showed distinct production of ammonia in the case of uric acid. Similar results were obtained by means of the alcohol precipitates obtained from the filtrates from *Aspergillus* and *Cladosporium*.

Referring to Shibata's negative results with *Aspergillus niger* and uric acid, it was found in similar experiments that *Aspergillus niger*, *Mucor Boidin*, *Phytophthora infestans*, *Isaria farinosa*, *Botrytis bassiana*, and *Cladosporium herbarum* all produce ammonia from uric acid, and that all, except *Cladosporium*, decompose hippuric acid with production of ammonia and benzoic acid.   N. H. J. M.

The Rate of Fermentation as Measured by Difference of Potential. M. C. POTTER (*Proc. Univ. Durham Phil. Soc.*, 1912, 4, 230—231. Compare *ibid.*, 1910, 3).—It has been shown previously that during the fermentation of sugar by yeast an $E.M.F.$ is developed. The author now finds that the measurement of the rate of fermentation by the development of the $E.M.F.$ and by the evolution of carbon dioxide as in Slator's method are in close agreement, so that the electrical method provides a ready means of determining the rate of fermentation.

Experiments are also quoted, showing that the carbon dioxide given off during fermentation carries an electric charge, and that the rate of fermentation is uninfluenced by the potential of the fermenting liquid.

F. B.

Fermentations with Yeast in the Absence of Sugar. IX. Fermentation of Keto-acids by Wine Yeasts. CARL NEUBERG and J. KERB (*Biochem. Zeitsch.*, 1912, 47, 405—412).—Wine yeasts, of which a large number of German varieties were investigated, exert the same action on pyruvic acid as the beer yeasts, giving rise to acetaldehyde (which was isolated as its *p*-nitrophenylhydrazone) and carbon dioxide. These yeasts also attack oxalacetic acid and *a*-keto-*n*-butyric acid.

S. B. S.

Fermentations with Yeast in the Absence of Sugar. X. The Fermentation of *a*-Ketobutyric Acid CARL NEUBERG and J. KERB (*Biochem. Zeitsch.*, 1912, 47, 413—420).—This acid is very readily attacked by various yeasts and yeast preparations. The actual course of fermentation is not yet ascertained, in that propaldehyde could only be isolated in small quantity (about 4%). *a*-Ketoglutaric acid is also very readily attacked; phenylpyruvic acid is also fermented, but not *ay*-diketovaleric acid.

S. B. S.

The Acidification of Musts by Yeasts during Alcoholic Fermentation. AUGUSTE FERNBACH (*Compt. rend.*, 1913, 156, 77—79). A study of the influence of the original acidity of the medium on the production of acids during the fermentation by yeasts of a saccharine liquid. Even in varying conditions the results show that the acidification produced by the yeasts, independently of their individual character, is subject to the acidity of the medium in which they function, low acidity in the medium favouring high acid production.

W. G.

Fixation of Elementary Nitrogen by Yeasts, Monilia candida, and Oidium lactis. ALEXANDER KOSSOWICZ (*Bied. Zentr.*, 1913, 42, 68—69; from *Zeitsch. Gährungsphysiol*, 1).—The results of experiments with (1) *Saccharomyces Pastorianus III Hausen*; (2) *Monilia candida*; (3) *Saccharomyces membranaefaciens*; (4) *Saccharomyces anomalus*; (5) *Oidium lactis*, cultivated in solutions containing sucrose (5%), glucose (0·2%), and mannitol (0·2%), in addition to minerals, showed in three months the following gains of nitrogen: (1) 4·8 and 5·2; (2) 6·2 and 6·8; (3) 6·9; (4) 7·4, and (5) 4·8 and 5·8 mg.

The air in the flasks was freed from combined nitrogen.

N. H. J. M.

Mode of Action of Dilute Solutions of Electrolytes on Germination. HENRI MICHEELS (*Bull. Acad. roy. Belg.*, 1912, 753—765. Compare A., 1910, ii, 883).—Germination experiments with wheat in electrolysed and non-electrolysed *N*/100-potassium chloride solutions through which chlorine was passed showed that chlorine was rendered more favourable by the cathode liquid and was poisonous in the non-electrolysed solution.

In the case of potassium hydroxide (25 c.c. of a 0·1% solution added to 500 c.c. of N/100-potassium chloride), a very injurious effect was observed in the non-electrolysed solution; its toxicity was diminished in the anodic liquid, but only in a slight degree.

Copper sulphate (N/200) in anodic solution, which is acid, is more toxic than the cathodic solution, which is only slightly acid. The solution is toxic when not electrolysed.

Comparing N/100-potassium chloride with electrolysed solutions in which the cathodic and anodic liquids received hydrochloric acid and potassium hydroxide respectively, the best results were obtained in the non-electrolysed solution and in the cathodic liquid notwithstanding the acidity, whilst the disappearance of the acidity of the anodic liquid only slightly diminished its toxicity.

The conclusion is drawn that anodic and cathodic liquids owe their characters in part to the liberated cations and anions, not passed to the chemical state. In solutions of electrolytes, the action of cations would not be exclusive, but only preponderating.   N. H. J. M.

Effects of Manurial Salts on the Germination of Different Plants. ALBERT RUSCHE (*J. Landw.*, 1912, 60, 305—365; from *Diss.*, Göttingen, 1912) —Potassium chloride does not act unfavourably on the germination of cereals, peas, rape, and beet, but is unfavourable in the case of clovers, serradella, lucerne, and lupins, especially white clover and serradella. Sodium chloride is more unfavourable than potassium chloride, except with barley, lupins, serradella, and rape. Magnesium and calcium chlorides generally have the same effect as potassium chloride, but not in every case; whilst ammonium chloride is injurious, especially with clovers. Nitrates are generally more favourable than chlorides; ammonium nitrate, however, resembles the chloride. Potassium sulphate is generally favourable, except with serradella; sodium sulphate is similar in its effects, whilst magnesium and calcium sulphates are also favourable. Of all the salts employed, sodium and potassium carbonates are the most favourable.

As regards the length of roots, nitrates produced the shortest roots with cereals. The longest roots were obtained with sulphates and phosphates.

In the case of peas the longest roots were obtained when no manure was employed. With red clover the longest roots were produced under the influence of sulphates and carbonates, the shortest with carbonates and chlorides.

The full results relating to germination, length and weight of roots, and the development of the above-ground parts of the different plants are given in numerous tables.   N. H. J. M.

Influence of Previous Conditions on the Value of the Respiratory Quotient of Green Leaves. LÉON MAQUENNE and EM. DEMOUSSY (*Compt. rend.*, 1912, 156, 28—34).—The authors have studied a number of abnormal cases where the respiratory quotient of leaves gathered in full sunlight was considerably lower than that of leaves which had been kept in the dark for several hours. They worked with leaves of sorrel, stonecrop, geranium, rhubarb, and *Sedum*

acre, and from their results they consider that the respiration of a plant is effected in two successive phases ; the first leading to a production of fixed acids, the result of an oxidation rendered incomplete owing to the slowness of penetration of the oxygen ; the second to a combustion of these acids.   It is necessary also to take into account the solution of the carbon dioxide in the cell-sap and the temperature, which has an influence both on the acidification and the absorption of carbon dioxide by the leaf.

Working with an *Aspidistra* leaf and observing the variation of pressure, using their manometric measuring apparatus (compare A., 1912, ii, 1201), they find that with leaves taken straight from the sunlight the pressure at first diminishes and then rises, whilst with leaves kept in the dark for some hours before measuring, the pressure rises immediately and continuously.   W. G.

Hydrolysis and Displacement by Water by Nitrogenous and Mineral Substances Contained in Leaves. GUSTAVE ANDRÉ (*Compt. rend.*, 1912, 155, 1528—1531. Compare A., 1912, ii, 198).—Chestnut leaves show much the same loss of nitrogen, phosphoric acid, and potassium, by exosmosis, when steeped in water, as do grains of wheat and haricot beans (compare A., 1912, ii, 591). After 255 days steeping, the leaves had lost 6·27% of their nitrogen, 74·14% of phosphoric acid, and 94·58% of potassium. Most of the loss occurred in the first few days, and it was found to be more rapid the younger were the leaves.   W. G.

Does Potassium Participate in the Building Up and Degradation of Carbohydrates in Higher Plants ? JULIUS STOKLASA and E. SENFT (*Zeitsch. landw. vers. Oesterr.*, 1912, 15, 711—736) —It is found that by the action of ultraviolet rays on nascent carbon dioxide and hydrogen in the presence of potassium hydroxide a photosynthesis occurs with the formation of formaldehyde, and that the latter subsequently condenses to furnish sugars ; the reduction of carbon dioxide in the cell does not take place in the absence of potassium hydrogen carbonate, even in the presence of nascent hydrogen ; and formic acid (which is subsequently reduced) is also found to be one of the products of this reaction.   F. M. G. M.

Enzyme Synthesis.   III.   Diastase and Starch of Plant Tissues. HAROLD C. BRADLEY and E. KELLERSBERGER (*J. Biol. Chem.*, 1913, 13, 425—430).—With some exceptions the results in this series are more favourable to the view of enzyme synthesis in the tissues, for no tissues which contain starch are destitute of diastase, although many tissues which contain diastase are free from starch.
                                                                   W. D. H.

Occurrence of Arsenic in the Vegetable Kingdom. F. JADIN and A. ASTRUC (*J. Pharm. Chim.*, 1912, [vii], 6, 529—535).—The occurrence of arsenic in the vegetable kingdom appears to be general, as the authors have detected its presence in some sixty-seven different kinds of vegetables, fruits, cereals, plants, parasitic plants, fungi, etc.

The quantity of arsenic found per 100 grams of substance varied from 0·008 mg. in dates to 0·266 mg. in radishes. Parasitic plants contained arsenic, even although they were not in direct contact with the soil, but there was no relation between the amounts of arsenic in the parasite and its support. Plants belonging to the same family do not invariably contain similar quantities of arsenic, but in the case of one and the same plant the portions containing chlorophyll contained more arsenic than the parts not exposed to light. It is pointed out that one of the sources of the arsenic found in animal organs lies in the vegetable substances consumed as food.   W. P. S.

Stimulative Action of Manganese and Copper Sulphates on Plants. L. Montemartini (*Bied. Zentr.*, 1913, **42**, 65; from *Staz. sper. agrar. ital.*, 1911, **41**, 564).—Manganese and copper sulphates absorbed from aqueous solutions stimulate respiration, the effect varying with different plants. Vine plants are stimulated by 0·001% manganese sulphate, whilst greater concentrations are injurious, and are injured by 0·01% of copper sulphate. Garden beans, and still more potatoes leaves, are more resistant and more stimulated.   N. H. J. M.

Demonstration of Carotinoids in Plants. Separation in Crystalline Form. C. van Wisselingh (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, **15**, 511—526).—The various methods employed in detecting the presence of carotinoids are described. Indications were obtained that several distinct carotinoids frequently occur in plants.   N. H. J. M.

Demonstration of Carotinoids in Plants. Behaviour of Carotinoids towards Reagents and Solvents. C. van Wisselingh (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, **15**, 686—692).—In presence of carotinoids a blue coloration is produced by strong sulphuric, sulphurous, and nitric acids, bromine water, and strong hydrochloric acid with a little phenol or thymol; iodine dissolved in potassium iodide solution or chloral hydrate gives a green coloration. Two new reagents were also employed: concentrated solutions of antimony trichloride and of zinc chloride, both in 25% hydrochloric acid, which colour crystals of caratinoids dark blue.

Lists of flowers and other parts of plants which were tested with the different reagents are given.   N. H. J. N.

Demonstration of Carotinoids in Plants. Leaf of Urtica dioica, the Flower of Dendrobium thyrsiflorum and Hæmatococcus pluvialis. C. von Wisselingh (*Proc. K. Akad. Wetensch. Amsterdam*, 1912, **15**, 693—700)·—The flower of *Dendrobium thyrsiflorum* contains two carotinoids, one of which, of a reddish-orange colour, is not common in plants, and perhaps belongs to the xanthophylls. The examination of *Haematococcus pluvialis* indicated the presence of a greater number of carotinoids than have hitherto been detected (compare Zopf, *Biol. Centr.*, 1895, **15**, 417; H. C. Jacobson, *Folia Microbiol*, 1912, **1**, 24).   N. H. J. M.

Mannitol in the Sap of Asparagus.   E. Busolt (*J. Landw.*, 1912, 60, 393—396).—The mannitol in the sap of asparagus is produced by fermentation, and is not originally present.

N. H. J. M.

Presence of Stachyose in the Haricot and in the Seeds of Some Other Leguminoseæ.   Georges Tanret (*Compt. rend.*, 1912, 155, 1526—1528).—The author has isolated stachyose in a crystalline form, by means of its strontium compound, from the haricot bean and the seeds of certain other leguminoseæ, namely, lentils, clover, galega, lupin, and the soja bean.   In all cases sucrose was present as well.   The lupeose, obtained as an uncrystallisable syrup from haricots and lupins by Schulze, was, therefore, stachyose in an impure state.   No stachyose could be isolated from pea-seeds.

W. G.

Presence of Adenine and Aspartic Acid in Mulberry Leaves.   Z. Mimuroto (*J. Coll. Agric. Imp. Univ. Tokyo*, 1912, 5, 63—65).—From 500 grams of air-dried mulberry leaves, 1·2 gram of adenine (as picrate) and 0·3 gram of aspartic acid were obtained.

N. H. J. M.

Action of Stimulants on Rice.   Manuel Rocas (*Bied. Zentr.*, 1913, 42, 41—42; from *Philippine Agric. Forester*, 1912, 1, 89).— Previous investigations indicate that there are no poisons which cannot act as stimulants on plants ; that compounds of gold, silver, platinum, mercury, tungsten, palladium, copper, nickel, cobalt, boron, tin, cadmium, tellurium, arsenic, iodine and fluorine are poisonous, whilst chromium, manganese, bismuth, sulphur and magnesium are only poisonous under certain conditions.

The following concentrations of the various compounds were found to be favourable : sodium borate, 1/1000 ; manganese sulphate, 1/1000; ferrous sulphate, 1/1000 ; ferric chloride, 1/5000 ; copper sulphate, 1/2000 ; nickel sulphate, 1/5000 ; cobalt nitrate, 1/10,000, and zinc sulphate, 1/1000 mol. solutions.

Mercuric chloride in 1/50,000 mol. solutions inhibited growth, whilst ferric chloride and copper sulphate (1/1000) are injurious, and sodium borate (1/100) somewhat injurious.

The optimum results for rice are generally much higher than previous experiments have shown for other plants.   The experiments were, however, not made with water-cultures, but in soil.   N. H. J. M.

Presence of Nicotinic Acid in Rice Bran.   Umetaro Suzuki and S. Matsunaga (*J. Coll. Agric. Imp. Univ. Tokyo*, 1912, 5, 59—61). —Nicotinic acid was obtained from rice bran, freed from fat, by extracting with 80—85% alcohol.   The acid had not previously been found in any vegetable substance.   The yield of picrate amounted to about 1 gram from 1 kilo. of bran.   N. H. J. M.

The Substitution of Different Chemical Elements for Zinc in the Culture of Sterigmatocystis nigra.   Maurice Javillier (*Compt. rend.*, 1912, 155, 1551—1552).—The author has

replaced the zinc in the culture medium of *Sterigmatocystis nigra* by a wide range of other elements, and, with the exception of one, namely, cadmium, they were all without influence on the crop. While the addition of zinc to the extent of 1 in 10,000,000 produces a crop 6·2 times as great as in its absence, the same concentration of cadmium produces a crop only 2·6 times as great, and cadmium has a marked injurious effect on the sporulation.   W. G.

Volatile Aliphatic Acids of Corn Silage. ARTHUR W. Dox and RAY E. NEIDIG (*J. Amer. Chem. Soc.*, 1913, 35, 90—93).—With reference to the work of Hart and Willaman (Abstr., 1912, ii, 1205) on the volatile fatty acids and alcohols in maize silage, the authors draw attention to their own paper on the subject (*Iowa Agric. Exp. Sta., Research Bull.*, 1912, 7, 32). The results are in fair agreement, except with regard to formic acid and methyl alcohol; in the latter investigation, only traces of formic acid were found and methyl alcohol was absent, whereas Hart and Willaman found 17% of formic acid in the volatile acids and 21% of methyl alcohol in the alcohols. Certain sources of error are pointed out in the methods employed by Hart and Willaman, and it is considered that these may account for the discrepancies.   E. G.

Action of Long-continued Exclusive Manuring on Plants and Soils. S. GRAF ROSTWOROWSKI (*J. Landw.*, 1912, 60, 371—392). —The results of experiments with potatoes showed that, when there is a tendency to leaf curl, it is desirable to employ potassium salts in moderation.

As regards the effect of manures on the composition of potato ash it was found that the ashes of potatoes from plots manured with potassium and with potassium + phosphorus + nitrogen were almost identical in composition, and there was also no difference between the ashes of potatoes from plots manured with nitrogen and the unmanured plot.

The composition of the ash of potato leaves varied considerably with different manures; potash varied from 5% (unmanured) to 33% (potassium manure), and lime varied from 21% (potassium alone, or with phosphorus and nitrogen) to 41% (unmanured). Application of sodium nitrate resulted in a high percentage of sodium in the leaf ash.

Notwithstanding the long-continued application of potassium manures, the potash in the ash of the tubers never reached 60%.

Experiments were also made to ascertain the effect of the long-continued manuring on the soil.   N. H. J. M.

Chemical and Physical Nature of "Roterden." EDWIN BLANCK (*J. Landw.*, 1912, 60, 397—400).—A reply to Hissink (A., 1912, ii, 981; compare van der Leeden and Schneider, *Internat. Mitt. Bodenkunde*, 1912, 2, 81).   N. H. J. M.

Analysis of a Florida Clay. ARCHIBALD A. HALL (*Proc. Univ. Durham Phil. Soc.*, 1912, 4, 228—229).—The author gives an analysis of a clay subsoil underlying peat, from Duval in the great swamp of Florida, and points out that the composition of this clay, on which

vegetation is now growing under conditions which approximate to those of the coal age, is very similar to that of a typical underclay, underlying coal.   F. B.

Osmosis in Soils.   Soils Act as Semipermeable Membranes.   I.   C. J. LYNDE (*J. Physical Chem.*, 1912, 16, 759—765).— The movements of water in soil have been attributed to gravitation, capillary action, and heat. To these must now be added osmotic pressure.

Osmotic cells of the Pfeffer type were prepared as follows: Glass tubes 150 mm. × 11 mm. diameter were closed at one end with cotton cloth and wire gauze. A layer of sterilised heavy clay subsoil was deposited in each tube, and consolidated against the cloth by centrifugal action. The tubes were filled up with 10% sugar solution, or 10% potassium sulphate solution, and immersed in distilled water. In each case water diffused into the cells osmotically through the clay. The rate of diffusion inwards was considerably greater at 24·5° than at 22·5°. It is probable that the solution leak outwards through the clay was considerable.   R. J. C.

Osmosis in Soils.   Soils Act as Semipermeable Membranes. II.   C. J. LYNDE and F. W. BATES (*J. Physical Chem.*, 1912, 16, 766—781. Compare preceding abstract).—Three pairs of osmotic cells were prepared with clay subsoil as already described, the layers of sterilised clay being 54 mm., 36 mm., and 18 mm. thick respectively. The solution filling the cell was the aqueous extract of the clay forming the membrane in each case. The cells were closed by rubber stoppers carrying capillary tubes. The predetermined capillary rise of each solution was deducted from the total rise, the remainder being the osmotic rise.

The osmotic pressures obtained with the thickest layers of clay were the highest, but the concentrations of the soil solutions were also highest in these cases. On the assumption that the osmotic pressures should be equal to these given by solutions of potassium chloride of equal electrical conductivity, the osmotic efficiency of the membranes was calculated to be only 2·5% (54 mm. membrane), 1·4% (36 mm.), and 1·0% (18 mm.), the efficiency being roughly proportional to the thickness of the membrane. An experiment with a membrane of clay 108 mm. thick gave still higher pressures. It is calculated that about 2 metres thickness of clay would be a perfect semipermeable membrane. In all cases the osmotic rise at 36·5° was somewhat higher than at 16·7°.

The soil used in the above experiments had the physical composition: sand 10·5%, silt 50·4%, clay 36·3%, organic matter 2·8%. A number of soils containing 44—61% of sand and only 12—16% of clay failed to show any decided osmotic properties.

It is suggested that osmotic effects play an important part in agricultural operations, particularly on heavy clay subsoils. Tillage, drainage, manuring, and mulching by favouring bacterial action increase the proportion of soluble matter in the soil, and therefore the amount of moisture which is raised osmotically through the subsoil. The same

effect may be brought about by the addition of mineral fertilisers and such substances as gypsum and salt which are not directly plant foods. There may be other substances which are not plant foods, but might be beneficial as fertilisers from the osmotic point of view.   R. J. C.

Importance of the Error of Analysis in Questions Relating to the Nitrogen Economy of Arable Soils. THEODOR PFEIFFER and EDWIN BLANCK (*Landw. Versuchs-Stat.*, 1912, **78**, 367—374).—A final attempt was made to obtain a satisfactory nitrogen balance with the experimental soils at Breslau. Six plots (9 sq. metres each) were selected, which had given similar amounts of crops during two years, and from each plot five samples of soil were taken. Ten or twelve nitrogen estimations were made with each sample. The experimental error was found to be ±0·00086, which would correspond with 25·8 kilos. of nitrogen per hectare to a depth of 25 cm. if the weight of the soil is taken as 3,000,000 kilos., or 32·2 kilos. if the total weight of soil is taken as 3,750,000 kilos. As this number has to be multiplied by three it would only be possible to show a difference exceeding 77·4 or 96·6 kilos. of nitrogen per hectare. With fewer samples or analyses the error would, of course, be greater. It must also be borne in mind that the nitrogen of crops is not all derived from the surface soil, but from the subsoil as well.   N. H. J. M.

Estimation of the Value of Plant Foods in Soils and Manures so far as Dependent on Solubility. J. G. MASCHHAUPT and L. R. SINNIGE (*Bied. Zentr.*, 1913, **42**, 16—20; from *Verslag. Landbouwkund. onderzoek. Rijkslandbouwproefstat.*, 1912, No. 11).— Single extractions of different phosphates with a definite volume of water containing carbon dioxide will not show the relative values of the manures. Better results will be obtained when successive extracts are made, and it is probable that a method of continuous extraction in which the dissolved substances are at once removed will give better results than intermittent extraction.

Repeated extraction with fresh amounts of citric acid solution will probably indicate the relative values of phosphates. As, however, carbon dioxide is the chief solvent at the disposal of soil and roots, it is to be preferred to citric acid.   N. H. J. M.

Antagonism between Anions as Affecting Ammonification in Soils. CHARLES B. LIPMAN (*Centr. Bakt. Par.*, 1913, ii, **36**, 382—394).—Experiments in soils on the lowering of the toxicity of salts by the addition of other salts, as measured by the amount of ammonia produced. The first series, which deals with the antagonism between the salts of "white alkali," sodium chloride and sulphate, showed that addition of sodium chloride (0·2%) to the soil reduced the amount of ammonia from 54·46 to 30·73 mg., whilst the further addition of sodium sulphate (0·3%) increased the amount to 37·1 mg., less effect being produced by smaller or larger amounts of sulphate. In an experiment with sodium chloride and carbonate, the ammonia was reduced from 41·75 to 22·05 mg. by 0·2% of sodium chloride; sodium carbonate in amounts of 0·2% and more increased the ammonia

production, the greatest amount being 70·7 mg. with 0·7% of sodium carbonate in addition to 0·2% of chloride.

Further experiments are described in which sodium sulphate and carbonate were employed.

The results show that antagonism is shown most strongly between sodium carbonate and sodium chloride ; next between sodium carbonate and sodium sulphate, and least between sodium chloride and sodium sulphate.

When 0·3 or 0·4% of sodium carbonate is added to soil containing 0·9% of sodium sulphate there is an increased toxic effect ; when, however, the amount of carbonate is increased to 0·5%, the toxic effect of the sulphate is reduced, and with 0·6% of carbonate it is still further reduced.   N. H. J. M.

Influence of Organic Substances on the Decomposition and [Manurial] Action of Nitrogenous Compounds. MAX GERLACH and ALFRED DENSCH (*Bied. Zentr.*, 1913, 42, 21—30 ; from *Mitt. Inst. Landw. Bromberg*, 1912, 4, 259).—Pot experiments in which slightly humus, loamy sand manured with sodium nitrate both alone and with dextrose and straw respectively ; with an ammonium salt, alone and with dextrose ; and with dextrose and straw respectively, was kept for two months, after which the amounts of total nitrogen and the nitrates and soluble organic nitrogen were estimated.   The results showed that the total nitrogen changed very little, and indicated that the nitrogen added as ammonium salt and as nitrate was converted into insoluble proteins.

The same soil was then utilised for a series of vegetation experiments from April, 1909, to August, 1911, during which time, oats, mustard, rye, mustard and wheat were grown.

Dextrose and straw was always unfavourable to oats, but were beneficial to next plants (mustard).   The final results relating to nitrogen did not show any greater increase when dextrose was added than without.   Nitrogen applied as nitrate showed no loss, whilst application as ammonium sulphate resulted both in loss and gain. Straw alone and in conjunction with nitrate had only a slight effect on the total nitrogen.

The results indicate that ammonium salts and nitrates are converted into insoluble proteins in presence of undecomposed organic substances, and that the insoluble nitrogen compounds readily decompose into substances which plants can utilise.   N. H. J. M.

Relation of Active Potash to Pot Experiments. GEORGE S. FRAPS (*J. Ind. Eng. Chem.*, 1912, 4, 525—526).—An account of pot experiments with representative Texas soils, from which the conclusions are drawn that (1) the percentage of crops deficient in potash decrease with the increase of active potash in the soil ; (2) the percentage of crops injured by potash increase with the active potash in the soil ; (3) the effect of fertiliser potash on the weight of the crop decreases as the active potash content of the soil increases ; (4) the percentage of potash in the crop increases as the active potash in the soil increases ; (5) the total potash removed by the crop from

the soil increases as the active potash content of the soil increases. The term "active potash" is applied to that which is soluble in $N/5$-nitric acid.   F. M. G. M.

Effect of Sugar on the Fertility of Soils. THEODOR PFEIFFER and EDWIN BLANCK (*Landw. Versuchs-Stat.*, 1912, **78**, 375—388).— The results of plot experiments in which oats, beet, and oats were grown successively both without and with sugar and phosphoric acid, and with both sugar and phosphoric acid, showed that the application of sugar was slightly injurious the first year, and resulted in a slight increase the second year. In the third year there was no appreciable difference due to sugar. No evidence of increased fixation of nitrogen was obtained.   N. H. J. M.

Calcium Cyanamide. C. J. MILO (*Chem. Zentr.*, 1912, ii, 1054—1055 ; from *Med. Proefstat. Java-Suikerind.*, 1912, 427—527). —When calcium cyanamide is used as a manure, the lime is readily taken up and held by the soil, but the nitrogen is not held so well as in the case of ammonium sulphate. In spite of this no nitrogen is lost if the cyanamide is applied in the dry season and the soil is not heavily watered immediately afterwards, and none is lost by volatilisation if the manure is properly applied. The nitrogen is utilised mainly by bacterial agency, but is also absorbed in other ways. Comparison of calcium cyanamide with ammonium sulphate as a manure has not yet given definite results. Dicyanodiamide is not poisonous to sugar-cane, and although calcium cyanamide shows some toxic effects, it appears to be rapidly converted into harmless cyanamide in the soil.

                                                    T. A. H.

Behaviour of Calcium Cyanamide when Stored, and under the Influence of Soil and Colloids. G. HENSCHEL (*Bied. Zentr.*, 1913, **42**, 33—34; from *Cent. Bakt. Par.*, 1912, ii, **34**, 279).—Dry sterilised soil or colloids decompose cyanamide more quickly than when not sterilised. Under sterilised conditions, urea and dicyanodiamide are formed, but no ammonia. Experiments with different soils showed almost complete agreement between the intensity of the decomposition when sterilised and the production of ammonia when not sterilised ; an exception, however, occurred in the case of a sandy soil containing much humus, which showed a strong colloid, but feeble bacterial action.

When cyanamide is stored, a good deal of urea may be produced under some conditions ; different preparations show, however, considerable differences, both in this and other respects. No loss of nitrogen was ever observed, the lower percentages of nitrogen after storing being due to absorption of water and carbon dioxide.   N. H. J. M.

Organic Chemistry.

Some Reactions of Sodamide in the Presence of Liquid Ammonia. Formation of Ethylene Hydrocarbons. E. CHABLAY (*Compt. rend.*, 1913, 156. 327—330).—By the addition of alkyl iodides or chlorides to sodamide in liquid ammonia, primary amines are not the only products as has been supposed (compare Lebeau, A., 1905, i, 401, 512), but at the same time, except in the case of the methyl haloids, the corresponding olefine is formed in varying amounts. Starting from the ethyl haloids, the yield of olefine increases on passing up the series, and is always greater when using the chlorides than if the iodides are employed; thus *iso*butyl iodide gives a yield of 62·4% of *iso*butylene, whilst the chloride gives a yield of 83 6%. In this reaction sodamide resembles alcoholic potassium hydroxide in its behaviour (compare Meunier and Desparmet, A., 1907, i, 186).

W. G.

The Adsorption of Acetylene by Palladium Black. CARL PAAL and CHRISTIAN HOHENEGGER (*Ber.*, 1913, 46, 128—132).—In the previous investigation on the same subject (A., 1910, i, 807), the palladium black was suspended in aqueous solutions of various substances. The authors have now investigated the adsorption of acetylene, using either suspensions of palladium black in pure water, or else dry palladium black. The experiments in which 60% alcohol was used in place of pure water were also repeated.

In all cases the adsorption of the acetylene takes places slowly, and the results given do not point to any fixed ratio between the weight of palladium and the amount of gas adsorbed. It is probable that the acetylene is not completely adsorbed as such, but undergoes partial polymerisation.

When the dry palladium black is not completely free from oxygen, formation of feeble sparks occurs immediately it is brought into contact with the acetylene. T. S. P.

Acetylene or Acetylidene Compounds. The "Oxidation Rearrangement." HEINRICH BILTZ (*Ber.*, 1913, 46, 143—149).—Nef and his school assign to the halogen substitution products of acetylene an acetylidene formula, as, for example, $CI_2{:}O$, di-iodoacetylidene. No definite proof of this constitution has been afforded, and the facts observed are more in favour of the acetylene structure, $CI{:}CI$. Di-iodoacetylene is very readily formed from acetylene by the action of hypoiodites and iodine, the process involving simple substitution of iodine for hydrogen.

The reasons for the representation of dibromoacetylene as $CBr{:}CBr$ are discussed. E. F. A.

Sodium Silver Thiosulphate and Acetylene–Silver Acetylide. KSHITIBHUSHAN BHADURI (*Zeitsch. anorg. Chem,.* 1913, 79, 355—356).—Sodium thiosulphate is added to an ammoniacal solution

of silver nitrate, and acetylene is passed through the clear solution. The yellow precipitate is collected, washed with water and alcohol, and dried in air. It is stable in dry air, but is decomposed by water, yielding a brick-red product. The final products of decomposition are silver sulphide and sodium sulphate.

The yellow compound is soluble in ammonia, and is re-precipitated by acids, again dissolving in an excess to form unstable solutions, which evolve sulphur dioxide and acetylene. Analysis leads to the formulæ $2Na_2S_2O_3,7Ag_2S_2O_3,18Ag_2C_2,32C_2H_2$ for the yellow compound, and $4Ag_2S_2O_3,7Na_2S_2O_3,86Ag_2C_2,13C_2H_2$ for the red compound.

C. H. D.

The Production of Chlorine Substitution Products of Methane from Natural Gas. CHARLES BASKERVILLE and H. S. RIEDERER (*J. Ind. Eng. Chem.*, 1913, **5**, 5—8).—The authors have investigated the conditions necessary for the chlorination of the methane present in natural gas, especially those which would lead to the formation of carbon tetrachloride, from which chloroform could be obtained by reduction. The apparatus used was so designed that the gases could be constantly circulated through it, the circuit always containing a heater for heating the gases, and a condenser for condensing out the products formed. In the first trials the circuit also contained an arc, either between carbon or iron terminals, but this was omitted later, as it was found that chlorination was not effected by the combustion taking place in the arc. It was ultimately found that the primarily important condition for the chlorination is a source of light rich in the rays of the visible blue spectrum, that is, the spectrum from the bluish-green through the visible violet. The ultraviolet part of the spectrum plays little part in the reaction. Apparently the necessary source of light may be obtained by an arc, between iron electrodes, in the circuit, and in some experiments a 20—25% yield of a mixture of carbon tetrachloride and chloroform was obtained.

T. S. P.

Primary Dinitro-, Nitro-nitrite and Dialdoxime Compounds of the Aliphatic Series. II. Derivatives of the Heptane Series and Synthesis of Pimelaldehyde. JULIUS VON BRAUN and E. DANZIGER (*Ber.*, 1913, **46**, 103—110).—As has already been shown (von Braun and Sobecki, A., 1911, i, 830), the action of silver nitrite on aliphatic compounds of the type $I \cdot [CH_2]_n \cdot I$ gives a mixture of dinitro, nitro-nitrite, and dinitrite derivatives, the first two of these being reducible to dialdoximes and amino-alcohols respectively. These changes have already been performed with n equal to 4, 5 and 10, and are now extended to the heptamethylene chain.

$a\eta$-Di-iodoheptane was prepared from $a\epsilon$-dibromopentane by conversion of the latter into an organo-magnesium compound, causing this to react with monochloromethyl ether (compare Dionneau, A., 1906, i, 134) and hydrolysing the product with hydriodic acid. It was also obtained by the stages : dibromopentane, diaminopentane, dichloroheptane, and diphenoxyheptane, the last of which again is converted into di-iodoheptane by hydriodic acid. In the conversion of dichloro-

heptane into diphenoxyheptane by sodium ethoxide, a small quantity of α-phenoxy-ζ-methylene-*n*-hexane, b. p. 145°/12 mm., was obtained as by-product.

αη-Di-iodoheptane reacts vigorously with silver nitrite, producing a mixture which can be separated at 10 mm. into three fractions, b. p 108—140° (mainly *heptamethylene nitrite*, $NO_2 \cdot [CH_2]_7 \cdot NO_2$), 140—160° (mainly *η-nitroheptyl nitrite*), and 160—205°, the last on refractionating yielding pale yellow *αη-dinitroheptane*, b. p. 198—200°/10 mm. The second fraction when reduced with tin and hydrochloric acid yields *η-hydroxyheptylamine*, a strong base, b. p. 150—152°/10 mm. ; *benzoyl*, *nitrobenzoyl*, and *picrate* derivatives are oily ; *platinichloride*, solid, m. p. 157°.

αη-Dinitroheptane when treated with sodium ethoxide in alcoholic solution gives an immediate precipitation of the white *sodium* salt, the aqueous solution of which can be used for the preparation of the salts of the heavier metals, for example, the *copper* (green), *barium* and *calcium* salts ; with bromine, it forms an oily *bromide* (compare von Braun and Sobecki, *loc. cit.*), and with a diazobenzene solution there is obtained yellowish-red *αη-bisphenylazo-αη-dinitroheptane*,

$$N_2Ph \cdot CH(NO_2) \cdot [CH_2]_5 \cdot CH(NO_2) \cdot N_2Ph,$$
m. p. 139°.

The reduction of a solution of the sodium salt of dinitroheptane by gradual addition to a solution of stannous chloride in hydrochloric acid gives *pimelaldoxime*, $OH \cdot N{:}CH \cdot [CH_2]_5 \cdot CH{:}N \cdot OH$, a pale yellow, crystalline powder, m. p. 150—151°, from which, on boiling with dilute sulphuric acid, pimelaldehyde is not obtained, as it partly polymerises to a viscous oil, and partly becomes dehydrated to tetrahydrobenzaldehyde, semicarbazone, m. p. 211—212° (Wallach, A., 1906, i, 563). *Pimelaldehyde*, a pungent, colourless oil of b. p. 110—112°/13 mm., D_4^{20} 0·9895, is obtainable by the action of nitrous fumes on a suspension of the dioxime in cooled water until no more nitrous oxide is liberated ; it readily reduces Fehling's solution, and an ammoniacal silver solution, and gives a *semicarbazone*, m. p. 183° ; the *phenylhydrazone* and p-*nitrophenylhydrazone* are oily, whilst the *diphenylmethanedimethyldihydrazone*, $CH_2{<}^{C_6H_4 \cdot NMe \cdot N{:}CH}_{C_6H_4 \cdot NMe \cdot N{:}CH}{>}[CH_2]_5$ (structure not proved), is a yellow solid, m. p. 96—97°. The aldehyde resembles adipaldehyde in showing much less tendency to polymerise than do the other dialdehydes of this series.

A preliminary investigation has shown that glutaraldoxime when heated with mineral acids gives pyridine, probably by reason of the condensation of glutaraldehyde and hydroxylamine which are first formed. D. F. T.

Synthesis of an Unsaturated Hydrocarbon. CORNELIS J. ENKLAAR (*Chem. Weekblad*, 1913, **10**, 60—63).—A note on the preparation of unsaturated alcohols by the interaction of unsaturated aldehydes and unsaturated haloids in presence of zinc and ether, and the conversion of such alcohols into unsaturated hydrocarbons by heating with potassium hydrogen sulphate. On treatment with zinc filings or shavings and ether, crotonaldehyde and allyl iodide give a

good yield of $ac\text{-}heptadiene\text{-}\delta\text{-}ol$, $CHMe:CH\cdot CH(OH)\cdot CH_2\cdot CH:CH_2$. Its properties are still uninvestigated, but heating with potassium hydrogen sulphate converts it into a liquid. Repeated fractionation, finally over sodium, at 758 mm. gives three fractions, b. p. $105—110°$, $110—112°$, and $112°$. On cooling to $-76°$, these three fractions solidify. The first has m. p. $-35°$ to $-32°$, the second $-23°$ to $-21°$, and the third $-15°$ to $-14.5°$. One of these substances is believed to be an $a\gamma\epsilon\,heptatriene$, and their constitutions are to be determined. It is anticipated that the method will prove of general application.

A. J. W.

History of Distillation and of Alcohol. EDMUND O. VON LIPPMANN (*Zeitsch. angew. Chem.*, 1913, **26**, 46—47).—Polemical against Schelenz (this vol., i, 2).   T. S P.

Action of Magnesium on a Mixture of Ethyl isoValerate and Allyl Bromide. G. MUSKALENKO (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1862—1865).—Decomposition by means of water of the product of the reaction of magnesium, ethyl isovalerate, and allyl bromide yields $diallylisobutylcarbinol$, $CHMe_2\cdot CH_2\cdot C(OH)(CH_2\cdot CH:CH_2)_2$, which forms a colourless, mobile liquid, b. p. $92°/37$ mm., $D_4^{23}\ 0.8616$, $n_D^{23}\ 1.45682$, and exhibits the normal molecular weight in freezing benzene or boiling ether.   T. H. P.

Adipiopinacone. LOUIS MICHIELS (*Bull. Soc. chim. Belg.*, 1913, **27**, 25—26).—$Adipopinacone$, $OH\cdot CMe_2\cdot[CH_2]_4\cdot CMe_2\cdot OH$, m. p. $88—89°$, is obtained in the form of its $hydrate$, containing $2H_2O$, by the action of magnesium methyl bromide on ethyl adipate. The hydrate is obtained in large, white crystals, m. p. $56.5°$, which effloresce in air, and completely lose their water of hydration when left in a vacuum desiccator. By the action of warm dilute sulphuric acid, the pinacone is readily converted into $tetramethyl$-$hexamethylene$ $oxide$, $O{<}_{CMe_2\cdot CH_2\cdot CH_2}^{CMe_2\cdot CH_2\cdot CH_2}$, a liquid with an ethereal odour, b. p. $156—157°/756$ mm.   W. G.

Action of Magnesium on a Mixture of Allyl Bromide and Ethyl Levulinate. E. SCHTSCHERICA (*J. Russ. Phys Chem. Soc.*, 1912, **44**, 1853—1858).—The interaction of magnesium, allyl bromide (1 mol.), and ethyl lævulate (1 mol.), and subsequent decomposition of the product with water, should yield the ester,

$$C_3H_5\cdot CMe(OH)\cdot CH_2\cdot CH_2\cdot CO_2Et,$$
but this reaction could not be realised. No matter whether 1 mol. or 3 mols. of allyl bromide were employed, the resultant compound was always the γ-$glycol$, $C_3H_5\cdot CMe(OH)\cdot CH_2\cdot CH_2\cdot C(C_3H_5)_2\cdot OH$, which is a faintly yellow, syrupy, slightly mobile liquid with a characteristic odour, b. p. $157—159°/10$ mm., $D_4^{25}\ 0.9545$, $n_D^{25}\ 1.48712$. When boiled with 20% sulphuric acid solution, the glycol is converted into the corresponding $oxide$, ${}_{CH_2\cdot C(C_3H_5)_2}^{CH_2\cdot CMe(C_3H_5)}{>}O$, which is an almost colour-

less liquid with a peculiar pleasant odour, b. p. 104·5 –105·5°/10 mm., D_4^{25} 0·8905, n_D^{25} 1·46915, and has the normal molecular weight in boiling ether. T. H. P.

Synthesis of Lecithin. Adolf Grün (*Ber.*, 1913, 46, 125—127). —Polemical. A reply, to Langheld (this vol., i, 155; compare Grün and Kade, this vol., i, 158). E. F. A.

Thionium Dibromides of Sulphides. Vladimir V. Tschelincev (*J. Russ. Phys. Chem. Soc.*, 1902, 44, 1885—1894).—The action of bromine on ethyl sulphide in carbon tetrachloride solution yields the thionium dibromide, SEt_2Br_2, which forms yellow crystals and resembles oxonium compounds in its general characters, and also as regards the nature of the solvents in which it dissolves readily or with difficulty. With acetic acid, it forms solid solutions, but in freezing benzene it exhibit, the molecular weight, 199—211, the theoretical value being 250.

By excess of water, the dibromide is rapidly decolorised with develop· ment of a considerable quantity of heat and the formation of a white emulsion. Concentrated ammonia solution decomposes the thionium dibromide much less energetically than the corresponding oxonium compound, heat being developed and an oily layer of the sulphide formed at the surface of the liquid. Sodium hydrogen sulphite solution effects the decomposition rather more rapidly, and concentrated potassium hydroxide solution much more rapidly, than does water. Moist silver oxide converts these dibromides into the corresponding oxides, for example, $SMe_2:O$, which are appreciably more stable than the analogous oxonium compounds.

The heat of formation of the diethyl dibromide from the alkyl sulphide and bromine is 14·15 Cal. per gram-mol., that of the diamyl dibromide being 12·91 Cal. Measurement of the amounts of heat evolved when the reaction proceeds in carbon tetrachloride solutions of various concentrations shows that the solvent is virtually without influence in this respect.

As the heats of formation of the oxonium compounds corresponding with the above thionium compounds are 9·13 Cal. for $OEt_2:Br_2$ and 8·72 Cal. for $O(C_5H_{11})_2:Br_2$, it is to be expected that alkyl sulphides would displace the ethers from oxonium compounds. Calorimetric investiga- tions show that when the oxonium compound is prepared in absence of solvent, such displacement does occur, but does not proceed to com- pletion, at any rate within the limits of time available for calorimetric measurements; it appears probable that the bromine finally becomes distributed between the sulphide and the ether. When, however, a carbon tetrachloride solution of ethyl sulphide (1 mol.) is added to a solution of ether (1 mol.) and bromine (1 mol.) in the same solvent, 13·76 Cal. are developed; as this amount is somewhat less than the theoretical quantity, 14·15 Cal., for complete displacement of the ether from the oxonium compound by ethyl sulphide, it may be that here, too, the bromine is distributed between the sulphide and the ether. T. H. P.

Catalytic Acceleration of the Esterification of Organic Acid by means of Glucinum Compounds. OTTO HAUSFR and A. KLOTZ (*Chem. Zeit.*, 1913, **37**, 146).—Experiments on the solubility of glucinum acetate in various organic solvents have led the authors to the discovery that the rate of esterification of organic acids and alcohols can be considerably increased by the addition of glucinum acetate or hydroxide to the boiling mixture. The catalytic action of glucinum compounds is still more pronounced when the mixed vapours of the acid and alcohol are passed over the oxide heated at 310°. The authors claim that better yields are obtained by this process than by that of Sabatier (actually 70% and over), that there is no loss of catalyst, since the glucinum oxide after use can be regenerated by simple ignition, and that tertiary alcohols and acids of high molecular weight can be esterified in this manner. The following new esters have been prepared : tert.-*butyl* n-*octoate*, b. p. 241°; tert.-*amyl* n-*heptoate*, b. p. 137°, and tert.-*amyl* n-octoate, b. p. 229°.   H. W.

Mechanism of the Action of Bromine on Chlorides of Fatty Acids. ARTHUR MICHAEL and ERWIN SCHARF (*Ber.*, 1913, **46**, 135—138).—When butyryl chloride, saturated with hydrogen bromide at 0°, is heated in sealed tubes at 100°, double decomposition takes place with the formation of butyryl bromide and hydrogen chloride. It is probable therefore that the formation of hydrogen chloride by the action of bromine on acyl chlorides is not due to the decomposition of a bromine additive product, formed from the enolic modification of the chloride, but is brought about by the direct action of the chloride with hydrogen bromide produced during the reaction. This is not in agreement with Lapworth's (T., 1904, **85**, 30) interpretation of the change.

Proof is further given that by the action of bromine on butyryl chloride in sunlight some quantity of the β-derivative as well as the a-derivative is formed. Hydrogen chloride and bromide in equal proportions are liberated on opening the tube. When the contents were converted into the ethyl ester, and hydrolysed with barium hydroxide, considerable quantities of crotonic acid derived from the β-ester were obtained.   E. F. A.

Aliphatic Nitro-compounds. XIII. Preparation of a-Nitro-a-methylbutyric Acid. WILHELM STEINKOPF (*Ber.*, 1913, **46**, 98—100). —An unfinished attempt to prepare a tertiary nitrocarboxylic acid containing an asymmetric carbon atom.

[With HARRY GRUNUPP and LEO HUG.]—A mixture of butanoneoxime with anhydrous hydrogen cyanide is kept in a closed flask for four to eight days at the ordinary temperature, and the excess of acid then removed in a vacuum; crystals of a-*hydroxylamino-a-methylbutyronitrile*, OH·NH·CMeEt·CN, m. p. 61·5°, are obtained. When this substance is oxidised by the cautious addition of an acidified solution of potassium permanganate, a blue *oil* (probably a-nitroso-a-methyl-butyronitrile) is first formed, but disappears later with the production of a-*nitro-a-methylbutyronitrile*, NO_2·CMeEt·CN, an almost colourless oil, b. p. 87—88°/17 mm. Attempts to hydrolyse this to the corre-

sponding acid, or to convert it into an imino-ester hydrochloride were unsuccessful.   D. F. T.

Action of Alkali Sulphites on the Ethylenic Acids.
J. BOUGAULT and MOUCHEL-LA-FOSSE (*Compt. rend.*, 1913, **156**, 396—398).—It being known that, on adding benzoylacrylic acid to a solution of normal or sodium hydrogen sulphite, combination instantly takes place, giving the sodium salt of a saturated sulphonic acid (compare Bougault, *Ann. Chim. Phys.*, 1908, [viii], **15**, 299), the authors have compared the activity of different types of ethylenic acids in this reaction. A large number of ethylenic acids combine in this way with sodium hydrogen sulphite, giving acids of the type $CH_2R\cdot CH(SO_3Na)R'$, which are very soluble in water, and, on heating with aqueous sodium hydroxide to 160°, regenerate the original unsaturated acid. The more energetic is the acid and the more electronegative groups it contains, the more rapid is the fixation of the sodium hydrogen sulphite. Acids such as *cyclo*geranic, undecenoic, and oleic acids, and in general those with long, straight chains, do not combine with the sodium hydrogen sulphite even after prolonged heating. The reaction can be employed to estimate the amount of unsaturated acid in a mixture of saturated and unsaturated acids, and also permits of the separation of the saturated acid in a pure state.
                                                              W. G.

The Salts of Rare Earths with Hydroxycarboxylic Acids.
I. The Glycollates of the Rare Earths. GUSTAV JANTSCH and A. GRUNKRAUT (*Zeitsch. anorg. Chem.*, 1913, **79**, 305—321).—The internally complex salts of rare earths with hydroxycarboxylic acids might be expected to differ more widely in solubility than the normal salts, and therefore to be suitable for the purpose of separation. It is found that the glycollates of the cerium group are anhydrous, and crystallise in crusts, whilst those of the yttrium group crystallise in needles with $2H_2O$. The yttrium salt is the least soluble, then follow the lanthanum, cerium, and praseodymium salts, which are almost equal, and then, in order, the neodymium, samarium, and gadolinium salts. The solutions exhibit the normal reactions, but conductivity determinations show that complexes are present.

Lanthanum hydroxide dissolves in a warm solution of glycollic acid, the solution at first remaining clear, but at a definite temperature, depending only on the concentration, the complex salt separates as a precipitate, $La(C_2H_3O_3)_3$. The praseodymium, neodymium, and samarium salts behave in the same manner.

Gadolinium glycollate, $Gd(C_2H_3O_3)_3,2H_2O$, crystallises without first forming an unstable solution, whilst the yttrium salt behaves like those mentioned above.

The fractionation of the earths from xenotime, previously freed from cerium, has been carried out by adding a solution of sodium glycollate to the hot solution of the mixed nitrates. After each addition, in order to overcome the unstable condition, the mixture is stirred vigorously for two hours at 80—90°. It is then filtered, and the filtrate is treated in similar manner. Successive fractions show a

progressive increase in the atomic weight, whilst the spectra show a concentration of neodymium and praseodymium in the last fractions.

C. H. D.

Succinic Semialdehyde [β-Aldehydopropionic Acid]. EDMOND E. BLAISE and E. CARRIÈRE (*Compt. rend.*, 1913, **156**, 239—241).— A reply to Harries (A., 1912, i, 827), in which the authors uphold the views already expressed by Carrière (A., 1912, i, 410) that β-aldehydopropionic acid changes spontaneously into a polymeride which is termolecular, and that the bimolecular compound, m. p. 147°, of Harries (*loc. cit.*) is the compound obtained by the elimination of $1H_2O$ from two molecules of the aldehyde.   W. G.

General Method for the Preparation of the Ammonium Salts of Organic Acids. EDWARD H. KEISER and L. McMASTER (*Amer. Chem. J.*, 1913, **49**, 84—86).—On account of the hydrolytic action of water on the ammonium salts of organic acids, comparatively few of them have hitherto been prepared, and in the case of most dibasic acids only the ammonium hydrogen salts have been obtained. It has now been found that normal salts can be readily prepared by passing dry ammonia into a solution of the organic acid in ether or alcohol, or a mixture of the two. The salts are insoluble, and separate in the form of white precipitates. *Ammonium maleate, fumarate, mesaconate, citraconate, malonate,* and *phthalate* are described.   E G.

Sebacates and Cacodylates of the Rare Earths O. F. WHITTEMORE and CHARLES JAMES (*J. Amer. Chem. Soc*, 1913, **35**, 127—132; *Chem. News*, 1913, **107**, 75—77).—In an earlier paper (A., 1912, ii, 690) it was shown that yttrium can be separated quantitatively from the alkali metals by precipitation with ammonium sebacate. It has now been found that lanthanum and cerium can also be separated from the alkali metals in this way. The following salts are described: *lanthanum sebacate,* $[C_8H_{16}(CO_2)_2]_3La_2,2H_2O$; *praseodymium sebacate,* $[C_8H_{16}(CO_2)_2]_3Pr_2,2H_2O$; *neodymium sebacate,* $[C_8H_{16}(CO_2)_2]_3Nd_2,3H_2O$; *samarium sebacate,* $[C_8H_{16}(CO_2)_2]_3Sa_2,4H_2O$; *yttrium sebacate,* $[C_8H_{16}(CO_2)_2]_3Yr_2,4H_2O$.

On fractionally precipitating a solution containing chiefly the chlorides of yttrium, dysprosium, and holmium with sodium cacodylate, it was found that yttrium tended to accumulate in the early fractions, and holmium and dysprosium in the later fractions. On boiling a mixture of hydroxides, consisting mainly of those of neodymium, samarium, and gadolinium, with cacodylic acid and fractionally crystallising the cacodylates from hot water, neodymium collected in the more soluble fractions, whilst nearly all the terbium and dysprosium remained in the least soluble portions. The following salts have been prepared: *praseodymium cacodylate.* $(AsMe_2O_2)_6Pr_2,16H_2O$; *yttrium cacodylate,* $(AsMe_2O_2)_6Yr_2,18H_2O$; *thulium cacodylate,* $(AsMe_2O_2)_6Tm_2,16H_2O$.

Neodymium and samarium cacodylates have been described previously (A., 1912, i, 233).

The rare earth cacodylates readily form double salts with other salts, such as the chlorides, nitrates, and sulphates. The following are described: *lanthanum chloride cacodylate,*

$$2La(AsMe_2O_2)_3,LaCl_3,18H_2O ;$$
cerium chloride cacodylate, $2Ce(AsMe_2O_2)_3,CeCl_3,18H_2O$, *cerium sulphate cacodylate;* and *neodymium chloride cacodylate,*

$$2Nd(AsMe_2O_2)_3,NdCl_3,18H_2O.$$
E. G.

The Action of *p*-Bromophenylhydrazine on Glycurono-lactone. GUIDO GOLDSCHMIEDT and ERNST ZERNER (*Ber.*, 1913, **46**, 113—115).—In reply to Jolles (this vol., i, 9), the authors maintain their previous statement (this vol., i, 9), that even with purified *p*-bromophenylhydrazine the test for glycuronic acid is so uncertain as to be of little practical value. D. F. T.

Behaviour of Chloraloxime Towards Water and Alkalis. F. CARLO PALAZZO and V. EGIDI (*Gazzetta*, 1913, **43**, i, 57—69. Compare Palazzo, A., 1912, i, 946; Palazzo and Fazio, 1911, i, 421).—When Meyer's chloraloxime is kept for some days with ten times its weight of water, an acid solution is obtained, from which can be isolated a product having the composition of oximinoacetic acid; it has, however, an indefinite m. p., and is to be regarded as a mixture of two stereoisomerides. It differs from the oximinoacetic acid, m. p. 138°, already known, in yielding a red coloration with ferric chloride. When Meyer's chloraloxime is distilled, several liquid fractions, b. p. 65—85°/20—25 mm., are obtained, and also a portion, b. p. 85°/20 mm., which solidifies and has m. p. 56°. Even if carefully freed from the liquid form, the solid substance yields, when treated with water, a product similar to that given by the original mixture.

By the action of hydroxylamine hydrochloride on bromal hydrate, *bromaloxime* is obtained in acicular crystals, m. p 115°; it has the composition and molecular weight required by the formula

$$CBr_3 \cdot CH:NOH.$$

Oximinoacetic acid forms two *copper* salts, namely, a blue salt,

$$[OH \cdot N:CH \cdot CO_2]_2Cu,2H_2O,$$
and a dark green salt of the probable composition $\begin{matrix} CH:NO \\ CO_2 \end{matrix}>Cu.$
R. V. S.

Inosite-phosphoric Acid. ANTON RICHARD ROSE (*Biochem. Bull.*, 1912, **2**, 21—49).—A useful review with bibliography on the subject. W. D. H.

Syntheses of Alkylgalactosides by means of Emulsin, β-Propylgalactoside and β-Benzyl Galactoside. ÉMILE BOUR-QUELOT, HENRI HÉRISSEY, and MARC BRIDEL (*Compt. rend.*, 1913, **156**, 330—332).—The two galactosides have been prepared from galactose and the corresponding alcohols under the influence of emulsin by the method previously described (A., 1912, i, 946).

β-*Propylgalactoside*, m. p. 105—106° (corr.), $[a]_D$ – 8·86°, crystallises in long, white needles, having a slightly bitter taste. It is not hygroscopic, but is very soluble in alcohol and water, and gives a slight reduction with Fehling's solution.

β-*Benzylgalactoside*, m. p. 100—101°, $[a]_D$ – 25·05°, crystallises in long, white needles, having a disagreeable bitter taste. It is not hygroscopic, and gives but traces of reduction with Fehling's solution. Both of these galactosides are readily hydrolysed by emulsin in aqueous solution.   W. G.

Photochemical Synthesis of Carbohydrates. WALTHER LÓB (*Biochem. Zeitsch.*, 1913, **48**, 257—258).—A reply to Stoklasa, Sebor, and Zdobnický (this vol., i, 18).   S. B. S.

Cellulose. C. PIEST (*Zeitsch. angew. Chem.*, 1913, **26**, 24—30).— The viscosity of a solution of a cellulose nitrate decreases with time and, generally, a deposit settles on the bottom of the vessel containing the solution. Experiments have been made which show that the decrease in the viscosity is not due to the separation of this deposit from the solution.

It has been stated previously that, a diminution in the viscosity of a solution of cellulose nitrate is probably due to the presence of nitrates of oxycelluloses. It is shown now that if a viscous solution of a cellulose nitrate be mixed with a less viscous solution of a nitrate of a highly bleached cotton wool the viscosity of the mixture is considerably less than the calculated value, although if two solutions of the same cellulose nitrate, but of different concentrations (and, therefore, different viscosities), be mixed, the mixture has a viscosity which is very close to the calculated value.

Cellulose, when treated with oxidising agents, is known to yield oxycelluloses, the part soluble in sodium hydroxide solution being termed β-oxycellulose, whilst the insoluble portion is called a-oxycellulose. The results of numerous trials, based on determinations of the "copper value" and viscosity of a standard solution in a cuprammonium solution by Ost's method (compare A., 1911, i, 838), show that a-oxycellulose, when carefully freed from the degradation products grouped under the name β-oxycellulose, is chemically identical with normal cellulose, and differs from it only in that the fibres are much shorter and finer, owing to the attack of the oxidising agent.

It is also shown that the products of the action of acids on cellulose ("hydrocellulose"), or of a hot 30% solution of sodium hydroxide ("alkalised cellulose"; compare Ost and Katayama, A., 1912, i, 680), contain a portion insoluble in sodium hydroxide solutions which is unattacked cellulose.   W. H. G.

Preparation of Higher Aliphatic Chlorinated Amines. JULIUS VON BRAUN and H. DEUTSCH (*Ber.*, 1913, **46**, 228—231. Compare von Braun and Müller, A., 1907, i, 28).—The bis-imidochlorides of the type $CPhCl:N\cdot[CH_2]_n\cdot N:CPhCl$, obtained by the action of phosphorus pentachloride on the corresponding dibenzoylated diamine, when distilled undergo decomposition mainly into benzonitrile and the

dichloride, but to a slight extent a product $Cl \cdot [CH_2]_n \cdot N:CPhCl$, in which only one of the phenyl radicles has been eliminated, is obtained (compare von Braun and Danziger, A., 1912, i, 597). As the latter class of substance on hydrolysis would give rise to chloroamines, the method might prove valuable if the yield of the second class of product could be increased.

It is now found that at very low pressures the desired decomposition at one end of the chain is greatly favoured.

$\alpha\zeta$-Di-iodohexane reacts with potassium cyanide, giving suberonitrile, $CN \cdot [CH_2]_6 \cdot CN$, b. p. 176—178°/11 mm., which by successive reduction (by sodium and alcohol) and benzoylation is converted into $\alpha\theta$-*dibenzoyl-diamino-octane*, $NHBz \cdot [CH_2]_8 \cdot NHBz$. When the last substance is carefully fused with a bimolecular proportion of phosphorus penta-chloride and the resultant mixture warmed under a pressure of 0·1 mm., there distils into the receiver, which is cooled by liquid air, a mixture of benzonitrile, $\alpha\theta$-dichloro-octane, and θ-*chlorobenzo-octyl-amide*, $COPh \cdot NH \cdot [CH_2]_8 \cdot Cl$, colourless leaflets, m. p. 65°, the last of which is most conveniently purified by means of its *compound* with calcium chloride. θ-Chlorobenzo-octylamide is hydrolysed by hydrochloric acid at 150°, with the formation of θ-*chloro-octylamine*; *hydrochloride*, hygroscopic; *platinichloride*, m. p. 193—194° (decomp.), sparingly soluble. The base on treating its hydrochloride with alkali easily undergoes intramolecular change to a *base*, $C_8H_{17}N$, with an odour resembling pyridine; yellow *platinichloride*, m. p. 197°.

In an analogous manner by the distillation of dibenzoyldiamino-heptane and of dibenzoyldiaminododecane with phosphorus penta-chloride under a pressure of 0·1 mm., η-*chlorobenzoheptylamide*, $Cl \cdot [CH_2]_7 \cdot NHBz$, and μ-*chlorobenzododecylamide*, $Cl \cdot [CH_2]_{12} \cdot NHBz$, m. p. 65°, can be obtained in fair quantity.

The yields were 40%, 30%, and 30% of the theoretical in the heptane, octane, and dodecane series respectively. D. F. T.

Dibromides of Tertiary Amines. VLADIMIR V. TSCHELINCEV (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1894—1905).—With a view to the comparison of dibromides obtained from tertiary amines with oxonium and thionium dibromides (compare this vol., i, 245), the author has investigated their solubilities in various solvents, their molecular weights, and their chemical and thermochemical relations.

A general parallelism exists between the solubility of trimethyl-amine dibromide and those of oxonium and thionium dibromides. Also in freezing acetic acid, trimethylamine dibromide has the molecular weight corresponding with the simple formula NMe_3Br_2, and is hence completely analogous to oxonium and thionium compounds in this respect (compare Hantzsch and Graf, A., 1905, i, 575).

Amine dibromides are somewhat more stable than the oxonium compounds towards moisture and are decomposed by ethyl alcohol, yielding hydrogen and ethyl bromides. When treated with excess of bromine, dibromides of amines are converted into new com-pounds, which possess peculiar properties distinguishing them from dibromides and represent a different class of perbromides.

The heat of formation of tripropylamine dibromide from its constituents is 39·72 Cal. per gram-mol., and that of triisoamylamine dibromide, 38·76 Cal. ; the carbon tetrachloride employed as solvent is without influence on the amount of heat developed (see this vol., i, 245).

Thermochemical investigation of the interaction of diethyloxonium dibromide or diethylthionium dibromide and tripropylamine in carbon tetrachloride solution shows that the tertiary amine displaces the ether or ethyl sulphide completely from oxonium or thionium compounds.

Ether has no action on diethyloxonium dibromide, and ethyl sulphide none on diethylsulphonium dibromide, but tertiary amine dibromides react energetically with tertiary amines, forming compounds separating from carbon tetrachloride in a felted mass of slender, pale yellow needles. The following thermochemical data were obtained :

$$2\mathrm{NPr_3Br_2 + NPr_3} = 23\cdot6 \text{ Cal.}$$
and $2\mathrm{N(C_5H_{11})_3Br_2 + N(C_5H_{11})_3} = 22\cdot9$ Cal. The compounds formed in this way are being investigated further.

Neither the structure suggested by Hantzsch (A, 1905, i, 576) nor that given by Cain (A., 1905, i, 747) for these amine dibromides seems to explain the reactions better than the simple formula.

<div align="right">T. H. P.</div>

Preparation of Oxan and the Properties of Salts of α- and β-Oxan. ALEXANDER P. LIDOV (*J. Amer. Chem. Soc.*, 1913, **35**, 132—134. Compare Abstr., 1912, i, 541).—Oxan is obtained most readily by the action of nitric oxide or nitrous oxide on charcoal at 150—300°. α-Oxan, O·C⫶N, is a stable gas and is not affected by hot platinised asbestos, whilst β-oxan, O·N⫶C, is rapidly decomposed under these conditions. The sodium salt of α-oxan is stable when heated, whilst that of β-oxan decomposes explosively. The silver salt of β-oxan is pale yellow and darkens rapidly on exposure to light; that of α-oxan is white and is less susceptible to the action of light. The iron and calcium salts are also described. The sodium salt of α-oxan gives a white precipitate with manganous chloride or aluminium chloride, whilst that of β-oxan does not yield a precipitate. The salts of α- and β-oxan gradually cease to evolve gas, and this is probably due to polymerisation taking place.

<div align="right">E. G.</div>

Action of Sulphuric Acid on Dicyanodiamide. HJ. LIDHOLM (*Ber.*, 1913, **46**, 156—160).—The interaction of dicyanodiamide with acids to form guanylcarbamide has been studied quantitatively and shown to be a bimolecular reaction. Guanylcarbamide is a sufficiently strong base to be titrated with sulphuric acid and methyl-orange.

Concentrated sulphuric acid acts on dicyanodiamide, liberating carbon dioxide and ammonia and forming guanidine. Guanylcarbamide is decomposed in a similar manner. These observations confirm the structure of dicyanodiamide as guanidinoformonitrile,

$$\mathrm{NH\text{⫶}C(NH_2)\text{·}NH\text{·}CN,}$$
<div align="right">E. F. A.</div>

The Tautomerism of Fulminic Acid. F. CARLO PALAZZO (*Atti R. Accad. Lincei*, 1912, [v], **21**, ii, 713—719. Compare A., 1907, i, 298, 489 ; 1909, i, 776).—The author's work on this subject has led him to conclusions similar to those of Ley and Kissel (A., 1899, ii, 485), according to which fulminic acid is to be regarded as a tautomeric substance related to the pseudo-acids. In the aqueous solution of fulminic acid, there is equilibrium between various saturated and unsaturated desmotropic forms. In the present paper this opinion is developed, and a new argument in its favour is drawn from the behaviour of sodium fulminate with azoimide, for in this reaction the fulminic acid reacts sometimes as carbyloxime and sometimes in the desmotropic form of formonitryl oxide, $HC:N:O$. The products of the reaction are hydroxytetrazole (I), m. p. 145°, and *iso*oxytetrazole (II),

(I.)　　HC——N·OH
　　　　N·N:N

(II.)　　N——CH
　　　　N·NH·N:O
m. p. 156°, and the relative proportions in which these two substances are formed depend on the temperature at which the reaction proceeds.

Catalysis. XIV. Reversible Addition of Alcohols to Nitriles Catalysed by Ethoxides. I. ELI K. MARSHALL, jun., and SOLOMON F. ACREE [and, in part, C. N. MYERS] (*Amer. Chem. J.*, 1913, **49**, 127—158).—A study has been made of the addition of alcohols to nitriles in presence of ethoxides as catalysts. It has been found that nitriles unite with ethyl alcohol in presence of sodium, potassium or lithium ethoxide, and that in every case the reaction is reversible. The percentage of imino-ester present when equilibrium is attained is the same whether the reaction is started with the nitrile or the imino-ester. The equilibrium point varies widely with the different compounds, the percentages of imino-ester formed with certain nitriles being as follows : butyronitrile, 0·90 ; propionitrile, 1·75 ; acetonitrile, 2·50 ; p-toluonitrile, 6·8 ; benzonitrile, 14·0 ; p-bromobenzonitrile, 27·2 ; m-bromobenzonitrile, 38·0 ; p-nitrobenzonitrile, 62·0 ; m-nitrobenzonitrile, 78·0 ; diisoamylcyanoamide, 98·0. In some cases, the equilibrium point varies considerably with changes in the concentration of the nitrile and the ethoxide, but in other cases shows but little fluctuation. Different ethoxides catalyse the reaction with different velocities, and the equilibrium points also often vary in such cases. The velocity of the reaction varies greatly with the different nitriles, p-nitrobenzonitrile reacting very rapidly, whilst o-toluonitrile scarcely unites with alcohol at all.

Certain experiments are described which show that the velocity of reaction can be expressed as a function of both the ethoxide ions and the non-ionised ethoxide.　　　　　　　　　　　　　　　　E. G.

Nitrile of Fumaric Acid and the Preparation of Methyl Maleate. EDWARD H. KEISER and L. McMASTER (*Amer. Chem. J.*, 1913, **49**, 81—84).—Keiser and Kessler (A., 1911, i, 949) have shown that fumaronitrile can be prepared by heating fumaramide with phosphoric oxide. It has now been found that the nitrile can be

converted into fumaramide by treating it with an alkaline solution of hydrogen peroxide.

Methyl maleate, which has only been obtained previously by the action of methyl iodide on silver maleate, has now been prepared by heating a mixture of maleic acid, methyl alcohol, and sulphuric acid under a reflux condenser. When the ester is left with solution of ammonia for several days, it gradually dissolves, and on evaporation a yellow viscous mass is obtained which is probably maleamide.

<div align="right">E. G.</div>

The Action of Light on Pigments. II. The Composition of Turnbull's Blue. ALEXANDER EIBNER and L. GERSTACKER (*Chem. Zeit.*, 1913, **37**, 137—139, 178—179, 195—197).—As a result of their experiments, the authors come to the conclusion that freshly prepared Turnbull's blue is not identical with Paris blue, but is a derivative of ferricyanic acid. It is not the most labile of the ferricyanides of the heavy metals, those of ferric iron, zinc, cadmium, lead, and copper being less stable. On long-continued washing or heating, a change takes place between the constituents of Turnbull's blue, resulting in the reduction of the ferricyanogen and oxidation of the ferrous radicle. The final result of such treatment is identical with Paris blue, the velocity of change depending on the conditions.

<div align="right">T. S. P.</div>

Spirocyclane, its Synthesis and Behaviour on Catalytic Reduction. NICOLAI D. ZELINSKI (*Ber.*, 1913, **46**, 160—172; *J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1873—1884).—The hydrocarbon formed by the action of zinc dust and alcohol on the tetrabromide of pentaerythritol has been regarded by Gustavson (A., 1896, i, 669) as vinyltrimethylene. Reasons are now given for formulating the compound as spirocyclane, $\begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix}\!>\!C\!<\!\begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix}$. The only other possible constitution is that of methylene*cyclo*butane.

The hydrocarbon is very readily and completely reduced in contact with nickelised asbestos and hydrogen at about 100°. No condensation product is formed, the gaseous mixture consisting entirely of saturated hydrocarbons. This behaviour eliminates any other constitution than that of the spirocyclane.

[With V. KRAVEC.]—This is confirmed by effecting the synthesis of spirocyclane by closing the two trimethylene rings one after the other.

By the action at 0° of hydrogen bromide on pentaerythritol, the *dibromohydrin*, $C(CH_2Br)_2(CH_2 \cdot OH)_2$, is obtained. This crystallises in well formed needles, m. p. 112°; the *diacetyl* derivative has b. p. 185°/13 mm.

When reduced with zinc dust, the *diacetate* of *dimethylolcyclopropane* is obtained, b. p. 115°/15 mm. The *glycol*,

$$\begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix}\!>\!C(CH_2 \cdot OH)_2,$$
has b. p. 126—127°/16 mm., D_4^{20} 1·0794, $n^{20\cdot5}$ 1·4705. When oxidised with permanganate, it yields *cyclo*propane-1 : 1-dicarboxylic acid.

Phosphorus tribromide converts the glycol into *dibromodimethyl-cyclopropane*, $\begin{matrix} CH_2 \\ CH_2 \end{matrix} > C \cdot (CH_2Br)_2$, b. p. 72—74°/13 mm., D_4^{20} 1·8022, $n = 1·534$. In addition, a tribromide resulting from the opening of the *cyclo*propane ring is formed.

On reduction of the dibromide, spirocyclane is obtained, b. p. 40—41·5°, D_4^{20} 0·7266, $n = 1·4120$, in agreement with earlier values.

[With B. SCHTSCHERBAK.]—When a mixture of spirocyclane and hydrogen is passed over platinum black at 70°, a mixture of ethyl-*cyclo*propane and pentane is formed. Using palladium black in the cold, it is possible to restrict the reduction entirely to one ring and obtain ethyl*cyclo*propane alone. In order to reduce the second ring, nickel must be used as catalyst—a temperature of 200° is necessary before *iso*pentane is obtained. The reduction of spirocyclane thus takes place in two stages and selective catalysts are required. Nickel in the cold reduces it only to ethyl*cyclo*propane. E. F. A.

Preparation of the Three Cymenes (Methyl*iso*propylbenzenes) and Three Menthanes (Methyl*iso*propyl*cyclo*hexanes). PAUL SABATIER and MARCEL MURAT (*Compt. rend.*, 1913, **156**, 184—187. Compare Sabatier and Senderens, A., 1901, i, 459).—Starting from the three tolyldimethylcarbinols, $C_6H_4Me \cdot CMe_2 \cdot OH$, the authors have prepared the three corresponding cymenes and menthanes, and examined their physical properties. The three carbinols were prepared either (1) by the action of magnesium methyl iodide on the ethyl o-, m-, and p-toluates, or on the three tolyl methyl ketones, or (2) by the action of acetone on the three magnesium tolyl bromides. The vapours of the three carbinols were completely dehydrated under the influence of thorium oxide at 350°, giving respectively o-, m-, and p-β-allyltoluene, $C_6H_4Me \cdot CMe \colon CH_2$, which by the action of slightly activated nickel at 200—220° yielded the corresponding cymenes. These substances underwent further hydrogenation when passed in the form of vapour over activated nickel at 170—180°, and the corresponding menthanes were obtained, all of which have been previously described. In certain cases the values of the physical constants now obtained differ from those previously given by other authors, namely, o-β-allyltoluene has b. p. 175°, D_0^{16} 0·9181, n_D^{16} 1·521 (compare Tiffeneau, A., 1907, i, 305).

o-Cymene has b. p. 175° (corr.), D_0^{0} 0·8902, n_D^{22} 1·501 (compare Sprinkmeyer, 1901, i, 519).

o-Menthane, b. p. 171° (corr.), D_0^{0} 0·8326, D_0^{21} 0·8135, n_D^{21} 1·447 (compare Kay and Perkin, T., 1905, **87**, 1066).

r-m-Menthane, b. p. 166—167° (corr.), D_0^{24} 0·7968, n_D^{24} 1·440.

d-m-Menthane was obtained by the hydrogenation of natural d-sylvestrene at 200° by activated nickel, and has b. p. 167—168°, D_0^{0} 0·8235, D_0^{23} 0·8116, n_D^{23} 1·446, $[\alpha]_D^{23}$ +1·60° (compare Knoevenagel, A., 1897, i, 610).

The para-isomeride has b. p. 167—168° (corr.), D_0^{0} 0·8134, D_0^{25} 0·8028, n_D^{25} 1·440 (compare Sabatier and Senderens, *loc. cit.*). W. G.

Systems Formed by Chloro- and Nitro-toluenes with Antimony Trihaloids. BORIS N. MENSCHUTKIN (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1939—1963).—o-, m-, and p-Chlorotoluenes melt at − 36·2°

(Haase, A., 1892, ii, 357, gave $-34°$), $-47·8°$, and $6·2°$ (Haase, *loc. cit.*, gave $7·4°$) respectively.

With antimony trichloride, *o*-chlorotoluene forms the compound, $SbCl_3,C_6H_4MeCl$, crystallising in long plates or needles, m. p. 3°, and the eutectic points and compositions are (1) 37·5° and
$$SbCl_3,24·1C_6H_4MeCl,$$

and (2) $-0·5°$ and $SbCl_3,1·950C_6H_4MeCl$. *m*-Chlorotoluene gives the compound, $SbCl_3,C_6H_4MeCl$, which is much less stable than that formed by the ortho-derivative and decomposes before melting; the eutectic points are (1) $-14°$, $SbCl_3,2·7C_6H_4MeCl$, and (2) $-49°$, $SbCl_3,24·1C_6H_4MeCl$. *p*-Chlorotoluene and antimony trichloride form no compound, the diagram showing only one eutectic point at $-7·5°$, corresponding with $SbCl_3,2·3C_6H_4MeCl$.

With antimony tribromide, none of the chlorotoluenes form compounds. The eutectic points and the corresponding compositions are for the ortho-compound, $-38·5°$ and $SbBr_3,23·8C_6H_4MeCl$; for the meta-compound, $-50°$ and $SbBr_3,32·3C_6H_4MeCl$, and for the para-compound, 2·5° and $SbBr_3,9·4C_6H_4MeCl$.

o-Nitrotoluene has m. p. $-8·5°$ (Knoevenagel, A., 1907, i, 202, gave $-9·4°$, and Ostromisslensky, A., 1907, i, 120, $-10·56°$) for the more stable α-modification and $-4°$ for the less stable β-form; the solutions in antimony trihaloid always correspond with the α-compound. The meta- and para-isomerides melt at 16° and 52·5° respectively.

o-Nitrotoluene and antimony trichloride give the compound
$$SbCl_3,C_6H_4Me·NO_2,$$

crystallising in slender needles, m. p. 34·5°; the eutectic points are $-18·5°$, corresponding with $SbCl_3,7·28C_6H_4Me·NO_2$, and 27·5° with $SbCl_3,0·56C_6H_4Me·NO_2$. *m*-Nitrotoluene and antimony chloride form a compound, which apparently melts at a higher temperature than the corresponding para-compound, but could not be obtained crystalline.

p-Nitrotoluene and antimony chloride form a compound
$$SbCl_3,C_6H_4Me·NO_2,$$

which crystallises with difficulty; the eutectic points and compositions are : (1) 7·5° and $SbCl_3,1·55C_6H_4Me·NO_2$, and (2) 3° and

$$SbCl_3,0·76C_6H_4Me·NO_2.$$
With antimony tribromide, *o*-nitrotoluene forms the compound $SbBr_3,C_6H_4Me·NO_2$, crystallising in needles, m. p. 32° (decomp.), isomorphous with those of the corresponding compound of antimony trichloride. The system exhibits one eutectic point, $-13·5°$, corresponding with $SbBr_3,10·8C_6H_4Me·NO_2$, and one transition point, 31°, corresponding with $SbBr_3,1·3C_6H_4Me·NO_2$. *m*-Nitrotoluene and antimony tribromide form no compound, the system showing only one eutectic point, $-9°$, corresponding with $SbBr_3,2C_6H_4Me·NO_2$. The para-derivative also forms no compound with the tribromide, the diagram consisting of two curves meeting at the eutectic point, 16°, for which the composition is $SbBr_3,1·3C_6H_4Me·NO_2$.

These results are discussed in relation to those obtained with benzene and its other substituted derivatives (*loc. cit.*).   T. H. P.
$Δ^1$-**Dihydronaphthalene.** FRITZ STRAUS and LEO LEMMEL (*Ber.*, 1913, **46**, 232—241).—If $Δ^2$-dihydronaphthalene, which was obtained

by Bamberger and Lodter (A., 1888, 292 ; 1896, i, 99) by the action of sodium and ethyl alcohol on naphthalene, is heated with an alcoholic solution of sodium ethoxide, it quantitatively undergoes isomeric change into the hitherto unknown Δ^1-dihydronaphthalene.

Crude Δ^2-dihydronaphthalene was purified by shaking in ethereal solution with an aqueous solution of mercuric acetate ; the crystalline mercury compound, after washing with ether, was dissolved in benzene, when a slight insoluble residue was obtained, apparently of the mercury compound of Δ^1-dihydronaphthalene, due to a trace of this hydrocarbon in the crude starting substance. The pure mercury compound, m. p. 119—120°, obtained on evaporation of the solution, when decomposed with a 30% solution of hydrochloric acid, gave pure Δ^2-dihydronaphthalene, leaflets, m. p. 24 5—25°, b. p. 94·5°/17 mm., which on heating for eight hours at 140—150° with sodium ethoxide in alcoholic solution was isomerised into Δ^1-*dihydronaphthalene*, b. p. 84—85°/12 mm., m. p. −8° to −7°, an unpleasant-smelling liquid which immediately decolorises permanganate ; when shaken with mercuric acetate, it is slowly converted into a white *mercury* derivative, which is insoluble in benzene, and does not melt below 250° ; the *dibromide*, colourless crystals, m. p. 70—71°, is quite distinct from that (m. p. 71·5—72°) of the Δ^2-isomeride, and when boiled with alcoholic potassium hydroxide gives an oily *substance* of characteristic odour, together with a little naphthalene.

When an emulsion of Δ^1-dihydronaphthalene in water is oxidised by the gradual addition of concentrated potassium permanganate solution, *o*-carboxyphenylpropionic acid is obtained, together with a quantity of a pungent *substance* of low m. p. The further reduction of Δ^1-dihydronaphthalene can be accomplished by the addition of its alcoholic solution to finely-divided sodium, the product being tetrahydronaphthalene.

The above method of formation of Δ^1-dihydronaphthalene disposes of the difficulty of reconciling the reduction of naphthalene through Δ^2-dihydronaphthalene to tetrahydronaphthalene with the behaviour of the analogous allylbenzene and propenylbenzene, only the latter of which is reducible by sodium and alcohol to a saturated homologue of benzene (Klages, A., 1903, i, 19, 329 ; 1904, i, 567) ; according to this, Δ^2-dihydronaphthalene should not be directly reducible. The preparation of tetrahydronaphthalene by Bamberger and Kitschelt (A., 1890, 1146) is to be attributed to the reduction occurring by the stages

$$C_6H_4{<}^{CH:CH}_{CH:CH} \rightarrow C_6H_4{<}^{CH_2\cdot CH}_{CH_2\cdot CH} \rightarrow C_6H_4{<}^{CH:CH}_{CH_2\cdot CH_2} \rightarrow$$

$$C_6H_4{<}^{CH_2\cdot CH_2}_{CH_2\cdot CH_2} \qquad\qquad \text{D. F. T.}$$

Triphenylmethyl. XXII. Ethers or Oxides in the Triphenylmethane Series. Moses Gomberg (*J. Amer. Chem. Soc.*, 1913, **35**, 200—210).—It is well known that diarylcarbinols can be converted into the corresponding ethers or oxides by heating them either alone or in presence of a dehydrating agent. A few oxides of the triaryl-

carbinols have also been reported in the literature, but the results of the present work show that most of the compounds thus designated were not in reality triarylmethyl ethers.

A general method is now described for the preparation of triarylmethyl ethers. These compounds are as stable as the peroxides, are not affected by exposure to the air, or by heating them to temperatures below their m. p.; they are not decomposed by water or dilute alkali hydroxide, even at 100°, but are hydrolysed when boiled with dilute acids, alcohol, acetic acid, or acetyl chloride.

When triphenylmethyl chloride is treated with silver oxide, oxidation takes place with formation of diphenylquinomethane and other products, but the ether is not obtained. If triphenylmethyl chloride is shaken with zinc oxide and ether in sealed tubes, it is reduced quantitatively to triphenylmethane, and this reaction furnishes a simple and rapid method for preparing the hydrocarbon. The oxides of cadmium, lead, nickel, cobalt, and magnesium do not react with triphenylmethyl chloride. When, however, a triarylmethyl chloride dissolved in a dry solvent, such as benzene, ether, carbon disulphide, or chloroform, is heated on the water-bath with mercuric oxide, the corresponding triarylmethyl ether is readily obtained in a good yield.

Triphenylmethyl ether, $CPh_3 \cdot O \cdot CPh_3$, m. p. 235—237° (decomp.), forms white crystals, and is soluble in about 25 parts of benzene at the ordinary temperature, or in 5 parts of boiling benzene; 1 gram dissolves in 11 c.c. of carbon disulphide or in 325 c.c. of ether.

Phenylfluorene ether, $\left(\substack{C_6H_4 \\ C_6H_4} > CPh \right)_2 O$, m. p. 232—233°, forms colourless crystals, and is soluble in about 6·5 parts of benzene or 100 parts of ether; it is readily converted into the peroxide, m. p. 193° (Gomberg and Cone, A., 1906, i, 822). The compound obtained by Kliegl (A., 1905, i, 187) by the action of acetic and sulphuric acids on phenylfluorenol is not identical with the ether now described.

Phenylxanthenol ether, $\left(O < \substack{C_6H_4 \\ C_6H_4} > CPh \right)_2 O$, m. p. 250—252°, forms pale yellowish-pink crystals, and is soluble to the extent of 1 gram in 12 c.c. of cold, or 5 c.c. of hot, benzene, or in 160 c.c. of ether.

p-*Methoxytriphenylmethyl ether*, m. p. 212°, is soluble to the extent of 1 gram in 25 c.c. of cold benzene.

p-*Acetoxytriphenylmethyl chloride*, m. p. 85—86°, obtained by the action of hydrogen chloride on a solution of the carbinol in benzene, forms white crystals; when treated with mercuric oxide, it is converted into p-*acetoxytriphenylmethyl ether*, m. p. 123—124° (decomp.), which crystallises in white needles, and is not identical with the substance to which this constitution was assigned by Bistrzycki and Herbst (A., 1901, i, 702); the latter was probably the carbinol as suggested by Auwers and Schroter (A., 1903, i, 821).

Another method has also been devised for preparing triarylmethyl ethers. When triphenylmethyl carbonate is heated under certain conditions, carbon dioxide is evolved and a nearly quantitative yield of triphenylmethyl ether is produced. The details of this method will be published subsequently. E. G.

Triphenylmethyl Ether. Moses Gomberg (*Ber.*, 1913, **46**, 225—228).—Although *triphenylmethyl ether* is not obtained in the action of silver oxide on triphenylmethyl chloride (compare Schlenk, this vol., i, 34), the application of mercuric oxide gives an almost quantitative yield of this substance (m. p. 235—237°) The reaction with mercuric oxide is a general one for the production of triaryl-methyl ethers. Triphenylmethyl carbonate (m. p. 205—210°) when heated with copper as a catalyst to 140°, also decomposes into triphenylmethyl ether and carbon dioxide.

The opinion is expressed that the behaviour of triphenylmethyl and its analogues is best explained by an equilibrium between the three structures represented by the tervalent carbon, the hexaphenylethane, and Jacobson's (A., 1905, i, 186) formulæ.

D. F. T.

Synthesis of Pyrene. Richard Weitzenbock (*Monatsh.*, 1913, **34**, 193—223).—Two schemes for the synthesis of pyrene have been followed. The first, which should have led to the preparation of

diphenyl-2 : 2'-diacetaldehyde, which might have condensed in a manner analogous to the formation of β-phenylnaphthalene from phenylacetaldehyde (Auwers and Keil, A., 1904, i, 26), was unsuccessful. The tetramethylacetal of the dialdehyde was obtained, but on hydrolysis it gave 4 : 5 : 6 : 7-dibenzo-$\Delta^{1\cdot4\cdot6}$-*cyclo*heptatriene-2-aldehyde (annexed formula), the ready closing of the seven-membered ring recalling the formation of 2-imino-1-cyano-4 : 5 : 6 : 7-di-benzo-$\Delta^{4\cdot6}$-*cyclo*heptadiene from diphenyl-2 : 2'-diacetonitrile (Kenner and Turner, T., 1911, **99**, 2104).
The other scheme was analogous to the preparation of 2 : 8-di-hydroxychrysene from βγ-diphenyl-aδ-dihydromuconic acid (Beschke, A., 1911, i, 874), and consisted in the condensation of diphenyl-2 : 2'-diacetic acid to dihydroxypyrene which could be reduced by means of zinc dust or hydriodic acid and red phosphorus.

Scheme A.—It was first attempted to prepare diphenyl-2 : 2'-diacrylic acid by the distillation of *methyl o-iodocinnamate*, white needles, m. p. 40°, b. p. 300—310°, with copper, but the decomposition proceeded to the formation of phenanthrene. The ethyl ester could not be obtained pure, and gave still worse results. The acid was obtained, however, by Perkin's synthesis on 2 : 2'-dialdehydodiphenyl (compare Mayer, A., 1911, i, 870), being accompanied by the lactone of diphenyl-2-carbinol-2'-carboxylic acid (Kenner and Turner, *loc. cit.*), and was converted into the *diamide*, $C_{18}H_{16}O_2N_2$, white needles, by means of thionyl chloride and ammonia.

A better way to arrive at diphenyl-2 : 2'-diacetaldehyde was sought in the application of Weerman's method (A., 1907, i, 132) to the *amide* of o-*iodocinnamic acid*. This was obtained by the action of thionyl chloride and ammonia on the acid, in light brown, quadratic leaflets, m. p. 204—205°, the crude chloride having m. p. 63—64°. When treated with sodium hypochlorite in methyl alcohol, *methyl*

o-*iodostyrylcarbamate*, $C_6H_4I\cdot CH{:}CH\cdot NH\cdot CO_2Me$, was obtained in colourless leaflets, m. p. 128—130°, which on hydrolysis gave o-*iodophenylacetaldehyde*, C_8H_7OI, in pleasant smelling, white needles, m. p. 35—36°. When heated with copper, extensive decomposition took place, which was also the case with the *phenylbenzylhydrazone*,

$$C_{21}H_{19}N_2I,$$

stout, colourless needles, m. p. 104—105°. However, the *dimethylacetal*, $C_{10}H_{13}O_2I$, which was obtained by Fischer and Hoffa's method (A., 1898, i, 659) as a colourless, mobile oil, b. p. 144°/19 mm., gave a good yield of diphenyl-2 : 2'-diacetaldehyde,

$$C_{12}H_6\cdot[CH_2\cdot CH(OMe)_2]_2,$$

in the form of a viscid, yellow oil, b. p. 210—211°/13 mm. On hydrolysis, an unsaturated aldehyde was obtained, in white, pleasant smelling needles, m. p. 108—109°, which gave phenanthraquinone on oxidation with chromic acid, and is, therefore, to be regarded as 4 : 5 : 6 : 7-*dibenzo*-Δ-$^{1:4:6}$-*cycloheptatriene* 1-*aldehyde*, rather than as phenanthryl-4-acetaldehyde. It gives a stable *dibromide*, $C_{10}H_{12}OBr_2$, in colourless needles, m. p. 133° (decomp.).

Scheme B.—Diphenyl-2 : 2'-diacetonitrile was hydrolysed by means of concentrated hydrochloric acid at 130—140° (compare Kenner and Turner, *loc. cit.*), and the acid was dehydrated with zinc chloride or, better, converted into the chloride with thionyl chloride and then condensed with aluminium chloride. The impure, reddish hydroxy-product gave pyrene when distilled with zinc dust or heated with hydriodic acid and red phosphorus at 200°. An attempt to convert dibromoditolyl into the nitrile by Mann's method for phenylacetonitrile (A., 1881, 1034) resulted in the formation of Kenner and Turner's 2-imino-1-cyano-4 : 5 : 6 : 7-dibenzo-$\Delta^{4:6}$-*cyclo*heptadiene.　　J. C. W.

Quaternary Salts of Alkylideneamines and a General Method of Converting Primary into Secondary Amines. HERMAN DECKER and PAUL BECKER (*Annalen*, 1913, **395**, 362—377). —The formation of a quaternary ammonium salt by the addition of an alkyl iodide to an alkylideneamine is practicable, but the product is often contaminated by other substances formed by (i) the dissociation of the salt into its generators, (ii) heterosperisis (Decker and Fellenberg, A., 1909, i, 116), (iii) intramolecular change, ring formation, or polymerisation of the salt.

Quaternary alkylideneammonium iodides are decomposed by water or alcohol in the sense of the equation :

$$CHR''{:}NRR'I + H_2O = R''\cdot CHO + NHRR' + HI,$$
whereby a very satisfactory method is secured of converting primary into secondary amines without any possibility of the formation of the tertiary amines or the quaternary salt. The yield of the secondary amine is usually more than 75%, being less, however, in the case of primary aromatic amines containing the amino-group in the nucleus.

β-Phenylethylamine reacts with benzaldehyde and with vanillin on the water-bath to form β-*phenylethylbenzylideneamine*,

$$CH_2Ph\cdot CH_2\cdot N{:}CHPh,$$
m. p. 33—34°, colourless prisms, and β-*phenylethylvanillylidenea* in

m. p. 108—109°, leaflets, respectively. The former and methyl iodide at 100° yield an additive compound which is decomposed by boiling 95% alcohol into benzaldehyde and *β-phenylethylmethylamine h driodide*, $CH_2Ph \cdot CH_2 \cdot NHMe,HI$, m. p. 113—115°. The base, which is also produced by heating β-phenylethylglycine above its m. p., forms a *hydrochloride*, m. p. 156—157° (decomp.), *platinichloride*, m. p. 225—226° (decomp.), and *picrate*, m. p. 141—143°. β-Phenylethylethylamine, prepared in a similar manner, forms a *hydriodide*, m. p. 166—168°. Methyl-*p*-toluidine, prepared in a similar manner from benzylidene *p*-toluidine or heptylidene-*p*-toluidine, forms a *hydriodide*, m. p. 134—137°, pale yellow leaflets, and a *picrate*, m. p. 130—132° (decomp.), which is very sparingly soluble in benzene. Ethylaniline, methylaniline, and methyl*iso*butylamine have also been prepared by this method. C. S.

The Nitro-derivatives of *o*-Cresyl Oxide [*o*-Tolyl Ether] and *o*-Cresylene Oxide [Di-*o*-tolylene Oxide]. ALPHONSE MAILHE (*Compt. rend.*, 1913, **156**, 241—243. Compare this vol., i, 173).—On nitrating *o*-tolyl ether in acetic acid solution, a viscous liquid is obtained which, by distillation under reduced pressure, yields *5-nitro-o-tolyl ether*, $C_6H_4Me \cdot O \cdot C_6H_3Me \cdot NO_2$, yellow needles, m. p. 125°; this on reduction with iron and acetic acid gives the corresponding *amine*, m. p. 98°. If the nitration is effected in cold fuming nitric acid, by gradual addition of the ether to the acid, 5 : 5'-*dinitro-o-tolyl ether*, $O(C_6H_3Me \cdot NO_2)_2$, is obtained as a white powder, m. p. 270°, which on prolonged nitration with fuming nitric acid, containing a little sulphuric acid, is converted into 3 : 5 : 3' : 5'-*tetranitro-o-tolyl ether*,

$$O[C_6H_2Me \cdot (NO_2)]_2,$$

m. p. 115°.

Di-*o*-tolylene oxide nitrates very readily in acetic acid solution on warming, giving *nitrodi-o-tolylene oxide* $O{<}^{C_6H_3Me}_{C_6H_2Me \cdot NO_3}$, m. p. 108—109°, giving by reduction the corresponding *amine*, m. p. 92°, which gives a red coloration in alcoholic solution with calcium chloride.

By warming di-*o*-tolylene oxide with fuming nitric acid, a *dinitro*-derivative is obtained, crystallising in yellow needles, m. p. 170°. By warming this compound with fuming nitric acid, *tetranitrodi-o-tolylene oxide*, $O{<}^{C_6H Me(NO_2)_2}_{C_6HMe(NO_2)_2}$, is obtained as a white powder, m. p. 210°.

W. G.

The Action of Aldehydes on Phenols. HERMANN WICHELHAUS (*Ber.*, 1913, **46**, 110—112).—A continuation of research as to the origin of the dyes in certain woods (compare A., 1910, i, 868).

Formaldehyde has been detected in certain trees (Curtius and Franzen, A., 1912, ii, 978 ; Kleinstück, A., 1912, ii, 1202), and the author has, therefore, examined the action on phenols of trithioformaldehyde, which possesses the advantage of a lower volatility. In the presence of zinc chloride, condensation occurs with β-naphthol, resor-

cinol, α- and β-anthrols, and dihydroxynaphthalene, producing deeply coloured fusions which are difficult to purify. It is probable that one molecule, CH_2S, condenses with two of the phenol.

If the aldehyde is first combined with sodium sulphite (D.R.-P. 87335), the condensation follows another course, involving two molecules of aldehyde and two of the phenol; the products are colloidal substances often yielding fluorescent solutions, and possess dyeing power.

β-Naphthol after conversion into the acid, $OH \cdot C_{10}H_6 \cdot CH_2 \cdot SO_3H$, gives a condensation product which in solution possesses a green fluorescence, dyes wool a rose colour, and gives brightly coloured lakes with aluminium, manganese, and zinc salts. The product from β-naphtholsulphonic acid dyes silk greyish red.

2 : 7-Dihydroxynaphthalene when converted into 2 : 7-dihydroxy-naphthylmethanesulphonic acid, and heated slowly with zinc chloride solution in a vacuum, undergoes condensation below 100°, giving a blue *substance*, $C_{32}H_{16}O_6$; this dyes silk, and also can be converted into *nitro*-derivatives which also possess dyeing properties.

<div align="right">D F. T.</div>

The Silver Equivalent of Quinol. M. A. GORDON (*J. Physical Chem.*, 1913, **17**, 47—82).—The number of molecules of silver salt reduced per molecule of quinol varies with the conditions up to at least 10·5. In presence of acid no reduction occurs. In alkaline solution the amount of silver liberated from precipitated silver bromide depends on the efficiency of stirring, the time, temperature, and concentration of the alkali, but not on the incident light. At 20° in presence of excess of sodium hydroxide, the action appears to proceed in two stages, namely, up to about 6 equivalents of silver in a few hours, and then to about 8 in eighteen days. At 100° at least 9 equivalents are liberated in six hours.

The silver equivalent of *p*-benzoquinone is about two less than that of quinol. The liberation of 6 equivalents of silver by quinol corresponds with the formation of dihydroxy-*p*-benzoquinone, thus:

$$C_6H_4(OK)_2 + 6AgBr + 6KOH = C_6H_2(OK)_2O_2 + 6Ag + 6KBr + 4H_2O.$$

p-Benzoquinone and monohydroxy-*p*-benzoquinone may be intermediate products as suggested by Luther and Leubner (*Brit. J. Photo.*, 1912, **59**, 632—747), although the presence of neither monohydroxy- nor dihydroxy-benzoquinone has been demonstrated. *p*-Benzoquinone is undoubtedly an intermediate product, and by the action of the alkaline solution is transformed into quinol plus a peroxidised product which may be hydrogen peroxide (Mees and Sheppard) or hydroxybenzoquinone (Luther and Leubner). The Mees and Sheppard theory demands an infinite liberation of silver by a small amount of quinol in presence of sodium sulphite, and is inadmissible. The Luther and Leubner theory restricts the silver equivalent of quinol to 6, and therefore does not express the whole truth.

In strongly alkaline solution an excess of sodium sulphite increases the silver equivalent of quinol by 2 (from 6 to 8) for short runs, and by 1 (from 8 to 9) for long runs. The effect on the equivalent of benzoquinone is about half as great. When sulphite is added after the reduction by quinol has started, its effect is restricted. Hence

sulphite probably intervenes in the first and second stages of the oxidation of quinol equally. Some of the sulphite is oxidised, presumably to dithionate, although sodium sulphite alone is without action on silver bromide.

Ammoniacal silver nitrate, silver sulphite dissolved in sodium sulphite, and silver oxide in presence of sodium hydroxide give quinol equivalents of 7, 8, and 10·5 respectively for five minute runs.

Pyrogallol with and without sodium sulphite has a silver equivalent of a little over 3 when tested with silver bromide in a one hour run. Catechol under like conditions has an equivalent of 4·5, increasing to 5·5 in presence of sulphite. R. J. C.

o-Nitrophenyl Selenocyanate and *o*-Aminophenylselenol. HUGO BAUER (*Ber.*, 1913, **46**, 92—98).—When a solution of potassium selenocyanate is added gradually to a diazotised solution of *o*-nitroaniline in which the excess of free mineral acid has been neutralised by the addition of sodium acetate, nitrogen is liberated and a quantitative yield of *o-nitrophenyl selenocyanate*, yellow needles, m. p. 142°, is obtained. This action appears to be a general one, and was also successful with *p*-nitroaniline (p-*nitrophenyl selenocyanate*, pale yellow leaflets, m. p. 135°), sulphanilic acid, *p*-aminobenzoic acid, and arsanilic acid. On moistening with alcohol and then adding sodium hydroxide solution, *o*- and *p*-nitrophenyl selenocyanates undergo hydrolysis, forming coloured solutions (violet and red respectively) of the *sodium* salts of *o*- and p-*nitrophenylselenols*; the free phenylselenols could not be isolated, but the addition of a solution of lead acetate precipitated the *lead* salts, both of an orange colour.

The coloured alkaline solution of *o*-nitrophenylselenol soon loses its colour, undergoing oxidation even in a hydrogen atmosphere to *di-o-nitrophenyl diselenide*, yellow needles, m. p. 209°, which precipitates. The alkaline solution of *o*-nitrophenylselenol can also be obtained by the interaction of *o*-chloronitrobenzene and sodium hydroselenide in dilute solution in cold alcohol, and the diselenide can then be again obtained, the oxidation being aided if necessary by the addition of hydrogen peroxide. The former method is, however, the more satisfactory.

If the alkaline solution of *o*-nitrophenylselenol is treated near its b. p. with sodium hyposulphite a clear yellow or colourless solution of the *sodium* salt of *o-aminophenylselenol* is obtained, which on careful oxidation with hydrogen peroxide gives a precipitate of *di-o-aminophenyl diselenide*, orange needles, m. p. 81°. When a solution of this in hot alcohol is treated with hydrochloric acid and the resultant suspension of the *hydrochloride* reduced by zinc dust, the addition of sodium acetate precipitates the stable *zinc* salt of *o*-aminophenylselenol; the action of lead acetate on a suspension of this gives the orange *lead* salt. The reduction of the diselenide can also be effected by alkali and dextrose (compare Clasz., A., 1912, i, 851).

The action of benzoyl chloride on the zinc salt of *o*-aminophenylselenol in the presence of ethyl acetate produces 1-*phenylbenzoselenazole*, $C_6H_4{<}{\overset{N}{\underset{Se}{}}}{>}CPh$, colourless needles, m. p. 116—117° which could not

be obtained by the action of selenium on benzanilide (compare Hofmann, A., 1880, 386; 1887, 839). With picryl chloride the zinc salt undergoes condensation with the formation of 3:5-*dinitropheno-selenazine*, $C_6H_4 {<}{>}_{Se}^{NH} C_6H_2(NO_2)_2$ (compare Kehrmann, A., 1900, i, 61).   D. F. T.

Some Compounds of Cholesterol giving Liquid Crystals.
PAUL GAUBERT (*Compt. rend.*, 1913, **156**, 149—151. Compare A., 1907, ii, 932; 1908, i, 882; 1909, i, 920).—On heating cholesterol with the different tartaric acids for one minute a homogeneous isotropic liquid substance is obtained, which on cooling yields elongated rhombic crystals, possessing very great plasticity. The direction of the greatest refraction coincides with the long diagonal. At temperatures near to the point of fusion, the crystalline particles of the crystals arrange themselves so that the optical axis is perpendicular to the glass slide, and there are produced extensive, irregular films exhibiting all the characteristics of a uniaxial, optically positive substance. The hardness of the crystals rapidly increases up to that of gypsum as they become solid. Similar results are obtained by using malic and lactic acids instead of the tartaric acids. Maleic and malonic acids, but not fumaric acid, yield optically positive liquid crystals almost instantly on warming with cholesterol, but they are only stable within narrow temperature limits. The same applies to the compound obtained with succinimide and cholesterol. In order to obtain liquid crystals with cholesterol and succinic, cinnamic, or anisic acids, it is necessary to keep the mixture molten at 160° for one hour, when characteristic optically negative crystals are produced.
                                                                                W. G.

Action of Magnesium on a Mixture of Allyl Bromide and Benzoin. V. JAKUBOVITSCH (*J. Russ. Phys. Chem. Soc*, 1912, **44**, 1858—1861).—*Diphenylallylethylene glycol* [δε-diphenyl-Δª-pentene-δε-*diol*], $C_3H_5 \cdot CPh(OH) \cdot CHPh \cdot OH$, prepared by decomposing with water the product of the action of magnesium on allyl bromide and benzoin, forms small, colourless crystals, m. p. 89°, has the normal molecular weight in boiling benzene, and decolorises bromine. When boiled with 20% sulphuric acid, it is converted into the corresponding double *ether*, $\begin{matrix} CHPh\text{---}O\text{---}CHPh \\ CPh(C_3H_5) \cdot O \cdot CPh \cdot C_3H_5 \end{matrix}$, which crystallises in small, colourless needles, m. p. 125—126°.   T. H. P.

Influence of Constitution on the Rotatory Power of Optically Active Substances. V. **Esters of *d*-Carvoxime.** HANS RUPE and GEORG WOLFSLEBEN (*Annalen*, 1913, **395**, 136—148).—The following substances have been prepared generally by the interaction of *d*-carvoxime, pyridine (2 mols.), and the acyl chloride in benzene. Only the acetyl compound can be purified by distillation under diminished pressure; the others must be crystallised from absolute or dilute alcohol. Acetylcarvoxime has m. p. 63—64°, b. p. 158—161°/17 mm., and and $[a]_D^{20}$ +43·02°. *Crotonylcarvoxime*, $C_{10}H_{14}{:}NO \cdot CO \cdot CH{:}CHMe$, oil,

$[a]_D^{20}$ +33·46°; *diphenylacetylcarvoxime*, m. p. 65—66°, $[a]_D^{29}$ +17·63°; *cinnamoylcarvoxime*, m. p. 79°, $[a]_D^{20}$ +15·44°; *β-phenylpropionylcarvoxime*, oil, $[a]_D^{20}$ +26·23°; *a-phenylcinnamoylcarvoxime*,

$$C_{10}H_{14}{:}N{\cdot}O{\cdot}CO{\cdot}CPh{:}CHPh,$$

m. p. 139—140°, $[a]_D^{20}$ +37·06°; *aβ-diphenylpropionylcarvoxime*, m. p. 119—120°, $[a]_D^{20}$ +12·52°; *β-phenylcinnamoylcarvoxime*, m. p. 74—75°, $[a]_D^{20}$ +26·37°; *di-β-phenylpropionylcarvoxime*, m. p. 89—90°, $[a]_D^{20}$ +20·09°; *a-methylcinnamoylcarvoxime*, m. p. 68—69°, $[a]_D^{20}$ +16·33°; *β-phenyl-a-methylpropionylcarvoxime*, oil, $[a]_D^{20}$ +23·85°; *β-methylcinnamoylcarvoxime*, m. p. 78°, $[a]_D^{20}$ +22·45°; *β-phenyl-β-methylpropionylcarvoxime*, oil, $[a]_D^{20}$ +22·76°.

Excluding the *a*- and the *β*-phenylcinnamoyl- and diphenylpropionyl-carvoximes, the rotation of the saturated or the alkyl derivatives is distinctly greater than that of the corresponding unsaturated or phenyl derivatives. A parallelism cannot be traced between the carvoxime esters and the menthyl esters of the acids.

The entrance of a phenyl group into acetic acid or phenylacetic acid or the replacement of methyl by phenyl in acetic acid or crotonic acid diminishes the rotatory power of the carvoxime; the entrance of phenyl into the *a*- or the *β*-position in cinnamic acid increases the rotatory power. Just the converse behaviour is observed with the menthyl esters of the acids. The author is of opinion that the work so far recorded proves the necessity of dealing with substances containing one, or at most two, asymmetric carbon atoms in connexion with the problem of the relation between constitution and rotatory power. C. S.

The Determination of the Configuration of the Stereoisomeric Cinnamic Acids. CARL LIEBERMANN (*Ber.*, 1913, 46, 214—216).—A reply to Stoermer and Heymann (A., 1912, i, 974), indicating that theirs is not the first experimental proof of the steric configuration of *allo*cinnamic acid. D. F. T.

Fixation of the Alkali Hydrogen Sulphites by the Salts and Esters of the Acetylenic Acids. ED. LASAUSSE (*Compt. rend.*, 1913, 156, 147—149).—Under given conditions the salts or esters of the acetylenic acids of the type $R{\cdot}C{:}C{\cdot}CO_2H$ will unite with one or two molecules of an alkali hydrogen sulphite, giving an alkali salt of a monosulphonic acid, containing an ethylenic linking, or of a saturated disulphonic acid.
On heating phenylpropiolic acid (1 mol.) with normal sodium sulphite (1·5 mol.) in aqueous solution, in a sealed tube for eight hours at 100°, crystals of *disodium-β-sulphocinnamate*,

$$SO_3Na{\cdot}CPh{:}CH{\cdot}CO_2Na,$$

are obtained, which rapidly decolorise potassium permanganate in the cold. When heated in sealed tubes at 130° with concentrated hydrochloric acid it is decomposed, giving carbon dioxide, sulphur dioxide, and acetophenone. On fusion with sodium hydroxide at 200—220°, it yields sodium benzoate, sodium acetate, and sodium sulphite. The corresponding *potassium* salt has been prepared, starting with potassium sulphite. Methyl phenylpropiolate and sodium hydrogen sulphite under similar conditions yield *sodium methyl sulphocinnamate*,
$$SO_3Na{\cdot}CPh{:}CH{\cdot}CO_2Me.$$
If the heating is carried on for forty hours under reflux instead of in sealed tubes, three compounds are obtained, namely, *methyl disodium disulphophenylpropionate*, $C_2H_3Ph(SO_3Na)_2 \cdot CO_2Me$, disodium sulphocinnamate, and *sodium phenyldisulphopropionate*,
$$C_2H_2Ph(SO_3Na)_2 \cdot CO_2Na.$$
These three substances can be separated by their varying solubility in alcohol. The *barium* salt corresponding with the last compound has been prepared.

By similar methods the author has prepared *methyl disodium disulpho-octoate*, $C_5H_{11} \cdot C_2H_2(SO_3Na)_2 \cdot CO_2Me$, which is saponified by cold aqueous sodium hydroxide, giving the corresponding *trisodium* salt, which when heated with hydrochloric acid in sealed tubes at 120° yields the *acid*, $C_5H_{11} \cdot C_2H_2(SO_3Na)_2 \cdot CO_2H$.

He also prepared *methyl disodium disulphononoate*,
$$C_6H_{13} \cdot C_2H_2(SO_3Na)_2 \cdot CO_2Me,$$
the *trisodium* derivative, and the *acid*, $C_6H_{13} \cdot C_2H_2(SO_3Na)_2 \cdot CO_2H$.
<div align="right">W. G.</div>

Synthesis of β-m-Tolyl-α-methylhydracrylic Acid. A. GUBAREV (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1865—1867).—*Ethyl β-m-tolyl-α-methylhydracrylate*, $C_6H_4Me \cdot CH(OH) \cdot CHMe \cdot CO_2Et$, obtained by decomposing with water the product of the action of zinc on a mixture of ethyl α-bromopropionate and *o*-tolualdehyde, is a colourless, viscous liquid, with a pleasant odour, b. p. 171—172°/15—16 mm. The *acid* forms crystals, m. p. about 90°, but was not obtained pure. The *potassium* ($+ H_2O$), *silver*, *zinc*, *copper*, and *lead* salts were prepared, and the first two analysed.
<div align="right">T. H. P.</div>

Influence of Constitution on the Rotatory Power of Optically Active Substances. IV. HANS RUPE (*Annalen*, 1912, **395**, 87—135).—[With EDUARD LENZINGER.]—The following menthyl esters have been prepared by heating menthol and the substituted ethyl acetoacetate; acetoacetate, m. p. 36°, b. p. 154°/10 mm.; *methylacetoacetate*, $CH_3 \cdot CO \cdot CHMe \cdot CO_2 \cdot C_{10}H_{19}$, b. p. 148—149°/8 mm., $[a]_D^{20}$ $-63.59°$ in benzene, n_a 1·45436, n_D 1·45733, n_β 1·46317, n_γ 1·46797, D_4^{20} 0·9697, violet coloration with alcoholic ferric chloride; ethylacetoacetate, b. p. 155°/8 mm., $[a]_D^{20}$ $-60.26°$ in benzene, violet coloration with ferric chloride. The following menthyl esters are prepared by heating menthyl sodioacetoacetate and the requisite alkyl haloid in ethyl alcohol: *propylacetoacetate*, b. p. 162°/8 mm., $[a]_D^{20}$ $-57.27°$ in benzene, reddish-violet coloration with alcoholic ferric chloride; sec.-*octylacetoacetate*, b. p. 139°/0·1 mm., $[a]_D^{20}$ $-47.82°$ in benzene, brownish-red coloration with ferric chloride. *Menthyl phenylacetoacetate*, prepared from menthol and ethyl phenylacetoacetate at 140°, has m. p. 69°, b. p. 131—133°/0·1 mm., and develops a violet coloration with alcoholic ferric chloride. A freshly prepared solution of the ester in benzene is dextrorotatory, $[a]_D^{20}$ $+19.07°$, but rapidly becomes lævorotatory, and has $[a]_D^{20}$ $-67.55°$ constant after ten days. In another experiment, $[a]_D^{20}$ was initially $+28.70°$, and finally constant at $-67.16°$ after sixty-seven days. In alcohol, $[a]_D^{20}$ is initially $-28.27°$, and becomes constant at $-67.15°$ after forty-seven hours.

Menthyl benzylacetoacetate, prepared from menthol and ethyl benzyl-acetoacetate at 155°, has m. p. 68°, and $[a]_D^{20}$ – 106·97°, and pioduces with alcoholic ferric chloride a yellow coloration ch inging to greyish-yellow. By treatment with benzyl bromide and alcoholic sodium ethoxide at 0°, it yields *menthyl dibenzylacetoacetate*, m. p. 70°, $[a]_D^{20}$ – 25·28°.

Menthyl sodioacetoacetate and the requisite haloid in alcohol yield the following menthyl esters : *β-phenylethylacetoacetate*,

CH₂Ph·CH₂·CHAc·CO₂·C₁₀H₁₉,
b. p. 143°/0·1 mm., $[a]_D^{20}$ – 51·64° in benzene and – 53·79° in alcohol, violet coloration with ferric chloride ; *γ-phenylpropylacetoacetate*, b. p. 157°/0·1 mm., $[a]_D^{20}$ – 45·44° in benzene and – 48·99° in alcohol ; *allyl-acetoacetate*, b. p. 169—171°/13 mm., $[a]_D^{20}$ – 58·27° in benzene ; *cinnamylacetoacetate*, CHPh:CH·CH₂·CHAc·CO₂·C₁₀H₁₉, $[a]_D^{20}$ – 41·31° in benzene.

Menthyl benzoylacetate, CH₂Bz·CO₂·C₁₀H₁₉, prepared from ethyl benzoylacetate and menthol at 120°, has m. p. 41°, $[a]_D^{20}$ n benzene initially – 55·36° and finally – 63·97° after fifty hours, $[a]_D^{20}$ in alcohol initially – 56·41° and finally – 56·89° after six hours, is slightly soluble in alkalis, develops a deep red coloration with alcoholic ferric chloride, and forms a *semicarbazone*, m. p. 163°, which produces a dark green coloration with ferric chloride.

The following menthyl esters are obtained by treating menthyl sodiobenzoylacetate with the requisite alkyl haloid in alcohol ; *a-benzoylpropionate*, CHMeBz·CO₂·C₁₀H₁₉, m. p. 68°, $[a]_D^{20}$ – 57·73° in alcohol ; *a-benzoylbutyrate*, b. p. 208°/10 mm., $[a]_D^{20}$ – 55·86° in alcohol and – 54·27° in benzene ; *a-benzoylvalerate*, decomp. 180°/0 mm., $[a]_D^{20}$ – 52·35° in alcohol, violet-red coloration with alcoholic ferric chloride.

Ethyl benzoylphenylacetate and menthol at 160—165° yield *menthyl benzoylphenylacetate*, m. p. 116°, $[a]_D^{20}$ + 20·14° in benzene and – 12·12° initially and – 62·60° after eighty-nine hours in alcohol.
The following menthyl esters are obtained from menthyl sodio-benzoylacetate and the requisite haloid in alcohol : *a-benzoyl-β-phenyl-propionate*, m. p. 117°, $[a]_D^{20}$ – 60·83° in benzene ; *a-benzoyl-γ-phenyl-butyrate*, m. p. 77°, $[a]_D^{20}$ – 56·70° in benzene ; *a-benzoyl-δ-phenylvalerate*, $[a]_D^{20}$ – 43·97° ; *a-benzoyl-Δγ-pentenoate*, m. p. 53°, $[a]_D^{20}$ – 51·40° in benzene, violet-red coloration with ferric chloride in alcohol ; *a-benzoyl-δ-phenyl-Δγ-pentenoate*, m. p. 82—83°, $[a]_D^{20}$ – 48·10°.

By esterifying a-benzoyl-δ-phenyl-Δγ-pentenoic acid with menthol and repeatedly extracting the product with gasolin, it can be resolved in the sparingly soluble l-*menthyl* l-*a-benzoyl-δ-phenyl-Δγ-pentenoate*, m. p. 102—103°, $[a]_D^{20}$ – 86·66° in benzene, colourless needles, and the more soluble l-*menthyl* d-*a-benzoyl-δ-phenyl-Δγ-pentenoate*, m. p. 77°, $[a]_D^{20}$ – 25·95° in benzene ; the esters do not develop a coloration with alcoholic ferric chloride.

Menthyl benzoylacetate and benzaldehyde and a little piperidine, cooled in a freezing mixture, yield *menthyl a-benzoylcinnamate*, CHPh:CBz·CO₂·C₁₀H₁₉, m. p. 65°, $[a]_D^{20}$ – 77·43° in benzene white leaflets.

[With PAUL HÄUSSLER.]—a-Benzylcinnamoyl chloride and mentho

in benzene containing pyridine yield *menthyl α-benzylcinnamate*,
$$CHPh:C(CH_2Ph)\cdot CO_2\cdot C_{10}H_{19},$$
m. p. 64—65°, $[a]_D^{20}$ – 144·86° in benzene, and *α-benzylcinnamic anhydride*, $O[CO\cdot C(CH_2Ph):CHPh]_2$, m. p. 108—109°. The latter, which is stable to boiling aqueous sodium carbonate and is only slowly esterified by boiling alcohol and sulphuric acid, is also obtained directly from the acid chloride and pyridine.

Menthyl β-phenyl-α-benzylpropionate, m. p. 42—43°, $[a]_D^{20}$ – 24·41° in benzene, is prepared from the acid chloride, menthol, and pyridine in benzene.

[With GEORG WOLFSLEBEN.]—The reaction between potassium γ-phenylbutyrate and an excess of benzaldehyde and of acetic anhydride at 106° for forty-eight hours, and subsequently on the water-bath for 290 hours, leads to the formation of *γ-phenyl-α-benzylidenebutyric acid*, $CH_2Ph\cdot CH_2\cdot C(:CHPh)\cdot CO_2H$, m. p. 124—125°. Its *menthyl* ester, prepared from the acid chloride, menthol, and pyridine in benzene, is a yellow oil, $[a]_D^{20}$ – 23·00°.

Ethyl sodiomalonate and β-phenylethyl bromide in boiling alcohol yield *ethyl β-phenylethylmalonate*, $CH_2Ph\cdot CH_2\cdot CH(CO_2Et)_2$, b. p. 179°/10 mm., which reacts with alcoholic sodium ethoxide and benzyl bromide to form *ethyl benzyl-β-phenylethylmalonate*,
$$CH_2Ph\cdot CH_2\cdot C(CH_2Ph)(CO_2Et)_2,$$
b. p. 230°/10 mm. By hydrolysis with methyl alcoholic potassium hydroxide, the latter yields *benzyl-β-phenylethylmalonic acid*, m. p. 153° (decomp.), which is converted at 160° into *γ-phenyl-α-benzylbutyric acid*, $CH_2Ph\cdot CH_2\cdot CH(CH_2Ph)\cdot CO_2H$, m. p. 59—61°, b. p. 230°/8 mm. The acid chloride of the latter yields the *menthyl* ester, m. p. 102°, $[a]_D^{20}$ – 36·69°, by treatment with menthol and pyridine in benzene, and is converted by distillation under 15 mm. partly into 2-*β-phenylethyl-hydrindone*, $C_6H_4\!\!<^{CO}_{CH_2}\!\!>CH\cdot CH_2\cdot CH_2Ph$, m. p. 56—57° (*semicarbazone*, m. p. 227—228° [decomp.]). γ-Phenylpropyl bromide and potassium cyanide yield *γ-phenylbutyronitrile*, b. p. 132—133°/11 mm. The acid is converted by phosphorus trichloride in benzene into the *chloride*, b. p. 119°/9 mm., from which *menthyl γ-phenylbutyrate*, b. p. 205°/10 mm., $[a]_D^{20}$ – 57·00°, is obtained by means of menthol and pyridine in benzene.

The variations with time of the rotations of the preceding menthyl esters of β-ketonic acids in alcohol and in benzene have been measured in order to gain some idea of the magnitude and the velocity of the keto-enolic transformation. The acetoacetate and benzoylacetate rapidly acquire a constant rotation in a alcohol, but only after many hours or even days in benzene; the methylacetoacetate, benzoylpropionate, and benzoylphenylpropionate have constant rotations in benzene as well as in alcohol.

An unexpected fact of great importance has been found in the resolution by crystallisation of the menthyl esters of β-ketonic acids of enantiomorphous configuration. Such esters, the phenyleto-acetate, benzylacetoacetate, benzoylphenylacetate, and benzoylphenyl-pentenoate, all of which, it will be observed, contain a phenyl group, must have the ketonic structure. The case of the menthyl phenyl-

acetoacetate is interesting. Only l-menthyl d-phenylacetoacetate has been isolated, and it is dextrorotatory. As it changes to the enol in benzene, the activity due to the acidic portion disappears, the activity finally being due to the l-menthyl group only ; the time required for the attainment of a constant lævorotation varies in different experi· ments (probably owing to the action of a catalyst in the glass), in one case being ten days and in another sixty-five days The converse is observed with l-menthyl d-benzoylphenylacetate, which has a constant dextrorotation in benzene, but is lævorotatory in alcohol, reaching a maximum after four days.

Menthyl benzyl-, dibenzyl-, and benzylidene-acetoacetates, and the methyl-, phenyl-, benzyl-, s-phenylethyl-, cinnamyl-, and benzylidene-derivatives of menthyl benzoylacetate do not develop a coloration with alcoholic ferric chloride. In some cases the enolisation must be repressed by the ferric chloride, because menthyl benzoylphenylacetate, for example, which does not give a coloration with alcoholic ferric chloride, shows in alcohol a lævorotation which increases with time.

The author's results show that valuable conclusions regarding structure can be drawn from the molecular rotations, provided strictly homologous esters are being compared ; comparisons are not justifiable when an alkyl group is replaced by a phenyl group. C. S.

α-Hydroxy-γ-phenylcrotonic Acid. An Example of an Ether of a Ketone Hydrate. J. BOUGAULT (*Compt. rend.*, 1913, **156**, 236—239. Compare A., 1912, i, 770, and Fittig, A., 1898, i, 196).—By the controlled action of dilute sodium hydroxide on α-hydroxy-γ-phenylcrotonamide, and subsequent neutralisation with acid, an *acid amide* is obtained having the constitution

$$CH_2Ph \cdot CH_2 \cdot C(OH) \cdot CO_2H$$
$$\begin{array}{c} >O \\ CH_2Ph \cdot CH_2 \cdot C(OH) \cdot CO \cdot NH_2 \end{array},$$
which on heating loses two molecules of water, giving another *acid amide*, $C_{20}H_{19}O_4N$. The first compound is readily decomposed by alkalis or alkali carbonates quantitatively into ammonia and benzyl-pyruvic acid, but unlike the acid anhydrides is not hydrated by boiling with water or dilute acetic acid. W. G.

Esters of Aromatic Keto-acids. GRETE EGERER and HANS MEYER (*Monatsh.*, 1913, **34**, 69—93. Compare A., 1908, i, 26).— The pseudo- and normal esters of some benzoylated benzoic acids are described. In most cases the ψ-methyl esters, for which the sensitive colour reaction with concentrated sulphuric acid is characteristic, are produced by the action of thionyl chloride, but Goldschmiedt and Lipschitz had already shown (A., 1905, i, 132) that the n-ester resulted in the case of naphthoylbenzoic acid, whilst ψ-ethyl esters were hitherto unknown. It is now demonstrated that the ψ-ester is the primary product in all cases, but that under the influence of alcohol and mineral acids it may undergo further changes which result in the n-ester. To prevent this rearrangement, for example, in the case of the naphthoyl-benzoate, the mixture of the acid chloride and the alcohol is immediately poured into sodium carbonate solution. On the other hand, any ψ-ester may be converted into its isomeride by the action of

a mineral acid or thionyl chloride and an alcohol. In this way a
ψ-methyl ester may be transformed into a *n* ethyl ester, which might
be supposed to be due to the effect of mass action on the already
rearranged *n*-methyl ester. Since, however, prolonged heating with
methyl alcohol is necessary to convert ethyl *n*-benzoylbenzoate into the
n-methyl ester, whereas the ψ-ethyl ester gives the *n*-methyl ester in a
short time, the conclusion is drawn that the transformation of the
ψ-form into the *n*-form is not due to any instability of the chloride or of
the ester, but to the addition of alcohol to the lactone system under the
catalytic influence of hydrogen ions and the subsequent elimination of
alcohol from the methane carbon atom according to the scheme :
It thus becomes evident why the action of ammonia on the iso-
merides always results in the same amide, namely, that of the ketone
acid (compare Meyer, A., 1905, i, 133).

Some of the acids employed were derived from the chlorophthalic
acid which Auerbach obtained by the action of hypochlorites on
phthalic acid. Since this may be condensed with benzene and trans-
formed into β-chloroanthraquinone, it is to be regarded as 4-chloro-
phthalic acid.

Whereas methyl ψ-benzoylbenzoate may be prepared without pre-
caution, by the action of thionyl chloride and methyl alcohol, the
formation of the ψ-*ethyl* ester only succeeds when the mixture of the
chloride with excess of cold absolute alcohol is at once poured into cold
sodium carbonate solution. It crystallises in triangular tablets, m. p.
51—53°, and dissolves with lemon-yellow colour in concentrated
sulphuric acid. The *n*-ethyl ester (rhombic, $a:b:c = 1.9725 : 1 : 1.267$)
may be prepared by leaving the chloride with alcohol, by the usual
means or by boiling the ψ-methyl ester for a few minutes or the
n-methyl ester for a few hours with alcohol and thionyl chloride or
sulphuric acid. Conversely, methyl alcohol and thionyl chloride
transform the ψ ethyl ester into the *n*-methyl ester in a short time,
whereas the *n*-ethyl ester must be heated for fifty hours. In the same
way, methyl ψ-toluoylbenzoate and methyl ψ-methoxybenzoylbenzoate
(Meyer and Turnau, A., 1909, i, 710; m. p. 83° and not 63°) may be
converted into the *n*-esters.

The preparation of 4-chlorophthalic anhydride by Auerbach's

method has been improved; the compound has b. p. 291—295°, and when crystallised from dry ether has m. p. 94°, but after contact with moist ether the m. p. rises to that of the acid. When condensed with benzene in presence of an excess of aluminium chloride, it yields *benzoyl-4-chlorobenzoic acid*, m. p. 180·5°, which gives β-chloroanthraquinone (Graebe and Rée, T., 1886, 531) in concentrated sulphuric acid. The *acid chloride*, $COPh \cdot C_6H_3Cl \cdot COCl$, long needles, m. p. 114—117°, also readily yields the quinone on heating. The ψ *methyl* ester forms colourless needles, m. p. 68·5—69·5°, and the n-*ester* forms monoclinic crystals ($a : b : c = 1·8252 : 1 : 0·6878$; $β = 76°59'$), m. p. 102—104°.

The acid obtained by the condensation of 4-chlorophthalic anhydride with chlorobenzene dissolves in sulphuric acid with the formation of 2 : 6-dichloroanthraquinone, and is, therefore, 2-p-*chlorobenzoyl-4-chlorobenzoic acid*, which confirms the position of the halogen in the above benzoyl-4-chlorobenzoic acid. The acid has m. p. 195·5°, gives a well-defined *acid chloride*, m. p. 115—120°, from which, however, the ψ-ester could not be obtained crystalline. The n-*methyl* ester, from the transformation of the crude isomeride or by direct esterification, melts at 98°.

Methyl ψ-p-*chlorobenzoylbenzoate*, m. p. 101—102·5°; the n-*ester*, m. p. 109—110°, monoclinic crystals ($a : b : c = 0·92461 : 1 : ?$; $β = 73°40'$), and the n-*ethyl* ester, m. p. 88°, have also been prepared.

Phthalic anhydride condenses with p-dichlorobenzene when boiled with an excess of aluminium chloride in nitrobenzene; the 2-om-*dichlorobenzoylbenzoic acid*, radiating needles, m. p. 168°, yields 1 : 4-dichloroanthraquinone (Ullmann and Billig, A., 1911, i, 490). Similarly, 4-chlorophthalic anhydride and p-dichlorobenzene give 2-om-*dichlorobenzoyl-4-chlorobenzoic acid*, m. p. 157—160°, which condenses to form 1 : 4 : 7-trichloroanthraquinone and yields a ψ-*methyl* ester, m. p. 115—120°.

The constitution of the isomeric esters (A., 1908, i, 26) receives support from the molecular refractions, for methyl n-benzoylbenzoate, $[M.R.]_D = 67·98$, being a benzophenone derivative, shows exaltation (compare Auwers and Eisenlohr, A., 1911, ii, 782), whereas the ψ-ester gives the theoretical value for a hydroxylactone, $[M.R.]_D = 65·40$.

<div style="text-align: right">J. C. W.</div>

Isomeric Esters of Trichlorobenzoylbenzoic Acids. STEPHAN JAROSCHY (*Monatsh.*, 1913, **34**, 1—6. Compare preceding abstract). —The product of the condensation of 1 : 4-dichlorophthalic anhydride with chlorobenzene, 2-p-*chlorobenzoyl-3 : 6-dichlorobenzoic acid*,

$$C_{14}H_7O_3Cl_3,$$
crystallises in colourless leaflets, m. p. 157°, and yields 1 : 4 : 7-trichloroanthraquinone in concentrated sulphuric acid. The ψ-*methyl* ester, colourless crystals, m. p. 153—154°, and the ψ-*ethyl* ester, a white, crystalline powder, m. p. 150—151°, may be obtained by immediately adding the mixture of alcohol and acid chloride to sodium carbonate solution, and may be transformed into the n-esters by heating with thionyl chloride and the corresponding alcohol for some hours. The normal esters may also be obtained by the usual methods, give no

coloration in sulphuric acid, and melt at 90° and 105—106° respectively.   J. C. W.

Preparation of Amides and Acylation of the Amino-group.

HERMAN DECKER (*Annalen*, 1913, **395**, 282—299).—Hofmann's classical method of preparing amides and substituted amides by heating the ammonium salts of carboxylic acids or their salts with primary and secondary amines, which has fallen into disuse owing to its supposed disadvantages, is shown to be a simple and convenient method of preparation provided the optimum temperature (the temperature at which water is eliminated, it may be slowly, from the salt, whilst the dissociation of the latter is still hardly appreciable) is obtained, and is retained to the end of the reaction. A whole series of amides and substituted amides have thus been prepared by simply heating the acid and the amine at the optimum temperature. The reaction, which is analogous to the formation of an ester from an acid and an alcohol, is accelerated, as in the case of esterification, by catalysts.

[With WALTER KROPP, HEINRICH HOYER, CLEMENS ZOELLNER, and PAUL BECKER.]—Formophenylethylamide is obtained free from β-phenylethylamine formate, and in 96% yield by heating β-phenylethylamine and anhydrous formic acid in slight excess at 170—180° for four hours. In a similar manner, phenylacetyl-β-phenylethylamine (95% yield) is obtained from phenylacetic acid and the amine at 180°, and acetyl-β-phenylethylamine from acetic acid and the amine.

Piperonylacetamide, $CH_2O_2:C_6H_3·CH_2·CH_2·CO·NH_2$, m. p. 122—123°, colourless leaflets, can be prepared from the acid chloride and 25% aqueous ammonia, from *ethyl piperonylacetate*, b. p. 303°, and aqueous ammonia at 160—180° (bad yield), or from 3 : 4-methylenedioxy-phenylpropionyl chloride and 25% aqueous ammonia, is readily obtained by heating piperonylacetic acid for two hours at 200—220° in a current of dry ammonia. It is readily converted by the sodium hypochlorite method into homopiperonylamine (hydrochloride, m. p. 207—208°; picrate, m. p. 174—176°; *carbonate*, m. p. about 110°; *platinichloride*, m. p. about 225° [decomp.]).

Formohomopiperonylamide, $CH_2O_2:C_6H_3·CH_2·CH_2·NH·CHO$, m. p. 61—62°, is obtained almost quantitatively from the amine and anhydrous formic acid at 180—200°. *Phenylacetohomopiperonylamide*, $CH_2O_2:C_6H_3·CH_2·CH_2·NH·CO·CH_2Ph$, m. p. 96°, is obtained from the amine and phenylacetic acid at 160°.

Homopiperonoylhomopiperonylamine,

$$CH_2O_2:C_6H_3·CH_2·CH_2·NH·CO·CH_2·C_6H_3:CH_2O_2,$$

m. p. 119°, is prepared from the amine and homopiperonylic acid at 160° for eight hours. Homopiperonylic acid is obtained in 5% yield by oxidising safrole in well-cooled acetone with potassium permanganate and treating the precipitate with sulphurous acid, whereby piperonylic acid is precipitated ; the homopiperonylic acid is extracted from the filtrate by ether.

Anhydrous oxalic acid reacts with β-phenylethylamine at 180—200° to form oxalodi-β-phenylethylamide, m. p. 186°, in 61% yield, and with homopiperonylamine at 170—180° to form *oxalodihomopiperonyl-*

amide, $C_2O_2(NH\cdot CH_2\cdot CH_2\cdot C_6H_3:CH_2O_2)_2$, m. p. 196—197° (corr.), colourless needles.

Fagaramide (Thoms and Thümen, A., 1912, i, 115) can be synthesised by heating piperonylacrylic acid and *iso*butylamine at 190—200° for two and a-half hours. C. S.

The Oxidation of Substituted Aceanthrenequinones. D. Butesou (*Ber.*, 1913, **46**, 212—214. Compare Liebermann and Butescu, A., 1912, i, 467).—The substituted aceanthrenequinones behave on oxidation in a similar manner to aceanthrenequinone itself, yielding anthraquinonecarboxylic acids (Liebermann and Zsuffa, A., 1911, i, 202). The oxidation is effected in acetic acid solution by chromic acid.

β-Methylanthraquinone-α-carboxylic acid, yellow needles, m. p. 295°, is obtained in the oxidation of β-methylaceanthrenequinone.

β-Chloroanthraquinone-α-carboxylic acid, yellow needles, m. p. 260°, obtained from β-chloroaceanthrenequinone, is distinct from the β-chloro-anthraquinonecarboxylic acid described by Heller and Schülke (A., 1908, i, 994).

α-Chloroanthraquinone-α-carboxylic acid, obtained by the oxidation of α-chloroaceanthrenequinone, forms leaflets, m. p. 205°, which can be sublimed to give yellow needles; it is distinct from the isomeric substances described by Heller and Schülke (*loc. cit.*) and Fischer and Sapper (A., 1911, i, 279).

1 : 5-*Dichloroanthraquinone-4-carboxylic acid*, obtained from 1 : 5-dichloroaceanthrenequinone, has m. p. 250°.

1 : 8-*Dichloroanthraquinone-5-carboxylic acid*, from the corresponding aceanthrenequinone, forms yellow needles, m. p. 240°. D. F. T.

Action of Magnesium on a Mixture of Allyl Bromide and Phthalic Anhydride. A. Orlov (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1868—1870. Compare Bauer, Abstr., 1904, i, 417; 1905, i, 210).

Diallylphthalide, $C_6H_4\!\!<\!\!\begin{smallmatrix}C(C_3H_5)_2\\CO\end{smallmatrix}\!\!>\!\!O$, prepared by the action of water on the product of the interaction of magnesium, allyl bromide, and phthalic anhydride, is a pale yellow, slightly mobile liquid of pleasant odour, b. p. 184—185°/14 mm., D_4^{25} 1·0546, n_D^{25} 1·53614, and develops fluorescence on prolonged keeping. It unites with 4 atoms of bromine, giving a liquid *bromide*, $C_{14}H_{14}O_2Br_4$, of pleasant odour. T. H. P.

The Reaction between 5-Bromo-2 : 4 : 6-tri-iodo-1 : 3-dinitro-benzene and Ethyl Sodiomalonate. C. Loring Jackson and F. C. Whitmore (*Ber.*, 1913, **46**, 67—70).—The explanation (Jackson and Bigelow, A., 1911, i, 101) of the reaction between ethyl sodio-malonate and halogen-nitrobenzenes in which one of the halogen atoms of the latter becomes replaced by hydrogen is now tested by applying it to 5-bromo-2 : 4 : 6-tri-iodo-1 : 3-dinitrobenzene; this substance is found, in accordance with the hypothesis, first to form with the ethyl sodio-malonate, an *additive* compound which probably has the constitution

$CO_2Et \cdot CHI \cdot C(ONa)(OEt) \cdot C_6BrI_2(NO_2)_2$, which when acidified undergoes scission into $C_6HBrI_2(NO_2)_2$ and $CHI(CO_2Et)_2$, the latter substance then reacting with a second molecule of ethyl sodiomalonate with the formation of ethyl ethanetetracarboxylate.

The additive compound could not be isolated, but a mixture of 2-bromo-1 : 3 : 5-tri-iodo-4 : 6-dinitrobenzene and ethyl sodiomalonate in alcohol gives a deep red liquid ; if an excess of the halogen compound or of ethyl sodiomalonate is taken and a little of the filtered red liquid is evaporated, the percentages of sodium in the residue in the former case and of halogen in the latter are in accord with the above composition.

The direct coupling of the substituted benzene ring with the ethyl sodiomalonate is attributed to the possibility that the substituted ring is more negative than the iodine atom, and it is held that the formation of *p*-toluenesulphinic acid and ethyl ethanetetracarboxylate from *p*-toluenesulphonyl chloride and ethyl sodiomalonate (Kohler and MacDonald, A., 1899, i, 907) is in support of such a view.

D. F. T.

Polymerisation of Cinnamylideneacetic Acid by Light. C. N. RIIBER (*Ber.*, 1913, 46, 335—338).—The author has obtained the dimolecular form of cinnamylideneacetic acid by the action of light on cinnamylideneacetic acid.

Cinnamylideneacetic acid was exposed to the action of light until the product had a mean mol. wt. of about 260 in acetone. The complex mixture so obtained was treated with a large quantity of benzene, whereby considerable quantities of oxidation products were isolated. The residue obtained by evaporation of the benzene mother liquor, after successive treatment with cold and boiling benzene, left a white, crystalline residue of *bimolecular cinnamylideneacetic acid*, needles, m. p. 219°, mol. wt. in acetone solution 320, which was purified by solution in methylal and addition of benzene. The acid is very sparingly soluble in the usual solvents. The *silver* salt was

examined. The formula $\begin{array}{c} Ph \cdot CH \cdot CH \cdot CH : CH \cdot CO_2H \\ | \\ CO_2H \cdot CH \cdot CH \cdot CH : CHPh \end{array}$ is assigned to

the acid, since when oxidised by potassium permanganate in alkaline solution, it yielded oxalic and benzoic acids, and an *acid* which could not be obtained in the pure state but gave a *silver* salt, $C_{13}H_9O_6Ag_3$, and a *methyl* ester, $C_{16}H_{18}O_6$. Since it was stable towards potassium permanganate, its composition is probably represented by the formula

$$\begin{array}{c} Ph \cdot CH \cdot CH \cdot CO_2H \\ | \\ CO_2H \cdot CH \cdot CH \cdot CO_2H \end{array}$$

*allo*Cinnamylideneacetic acid is similarly, but more readily, polymerised by the action of light.

Bimolecular cinnamylideneacetic acid (m. p. 219°) differs greatly from the isomeric acid (m. p. 204°) obtained by the action of light on cinnamylidenemalonic acid (A., 1902, i, 617), particularly in regard to solubility in acetone. The latter acid, when oxidised by potassium permanganate, yielded benzoic and oxalic acids, together with a saturated *acid*, m. p. 134°. α-Truxillic acid could not be isolated. The formula

$$Ph \cdot CH \cdot CH \cdot CH \colon CH \cdot CO_2H$$
$$CO_2H \cdot CH \colon CH \cdot CH \cdot CHPh$$ is advanced for the acid m. p. 204°.

<div align="right">H. W.</div>

New Oxime of Santonin. GUIDO CUSMANO (*Atti R. Accad. Lincei*, 1912, [v], **21**, ii, 796—800).—When nitrosohydroxylamino-β-santoninoxime (Francesconi and Cusmano, A., 1909, i, 724) is heated with an equimolecular quantity of N-sodium hydroxide on the water-bath, nitrous oxide is evolved, and an oxime is formed, which is identical with the santoninoxime of Cannizzaro (A., 1886, 73). If, however, nitrosohydroxylamino-a-santoninoxime is similarly treated, a new *santoninoxime* of the same composition is produced; it differs from Cannizzaro's oxime in physical and to a certain extent in chemical properties, and is regarded by the author as representing the oxime of formula II, which is stereoisomeric with the oxime of formula I (Cannizzaro's oxime), adopting the formulæ deduced from the work of Angeli and Marino (A., 1907, i, 321).

<div align="center">(I.)   (II.)</div>
The new oxime crystallises with $1\frac{1}{2}H_2O$, in scales or in lustrous needles; on heating, it becomes red towards 180°, m. p. 230° (decomp.). In addition this a-oxime differs from the β-oxime of Cannizzaro in having a bitter taste, and in yielding the corresponding *santoninic acid*, $C_{15}H_{21}O_4N,3\frac{1}{2}H_2O$, m. p. 80°, when its solution in sodium hydroxide is exactly precipitated with acid. If this acid is kept at 100° for twenty hours, the original oxime is formed. The *hydrochloride* of the oxime crystallises in colourless scales, which change on keeping into large prisms; on heating, the hydrochloride undergoes gradual change until it melts at 168°. With water it yields the oxime, together with santonin and hydroxylamine hydrochloride.

When treated with sodium nitrite and acetic acid, the new oxime yields a *pernitroso*-derivative, $C_{15}H_{18}O_4N_2,H_2O$, which forms prismatic crystals, which become red at 175°, m. p. 197° (with evolution of gas). This compound differs from that obtained from the other oxime in m. p. and in water of crystallisation, but resembles it in giving santonin when heated with alkali, and yielding a blue coloration with a solution of diphenylamine in sulphuric acid.

Treatment of the β-oxime with methyl sulphate yields a *monomethyl ether*, $C_{16}H_{23}O_4N$ (which forms silky, acicular crystals, m. p. 184°), and also another *substance* having the same composition, but crystallising in long, thin needles, m. p. 196°.

Under the same conditions the a-oxime gives a *methyl ether* of the same composition, which forms large, prismatic crystals, m. p. 185°. A mixture of this ether with that of m. p. 184° has m. p. about 160°.

<div align="right">R. V. S.</div>

The Action of Oxalyl Chloride on Polynuclear Hydrocarbons. CARL LIEBERMANN and M. KARDOS (*Ber.*, 1913, **46**, 198—212. Compare A., 1911, i, 202, 387, 656; 1912, i, 464).— 2 : 4 : 2′ : 4′-Tetramethyldiphenyl, when oxidised by prolonged boiling with sodium dichromate and diluted sulphuric acid, gives in poor yield diphenyl-2 : 4 : 2′ : 4′-tetracarboxylic acid (compare Liebermann and Kardos, A., 1912, i, 465); the same acid is obtained with still more difficulty by the oxidation of 2 : 7-dimethylphenanthraquinone, in which phenanthraquinone-2-carboxylic acid can be isolated as an intermediate product.

Oxalyl chloride reacts with 2 : 4 : 5 : 2′ : 4′ : 5′-hexamethyldiphenyl at the ordinary temperature in carbon disulphide solution in the presence of aluminium chloride, giving a mixture of 1 : 2 : 4 : 5 : 7 : 8-*hexamethylphenanthra*-9 : 10-*quinone*, yellow prisms, m. p. 223—224° (the *monoxime*, yellow flakes, m. p. 178°, when submitted to the Beckmann rearrangement gives a *substance*, possibly the mononitrile of hexamethyldiphenic acid; the *monophenylhydrazone* exists in two forms, *α*- red needles, m. p. 187°, *β*- yellow needles, m. p. 143°, which are possibly *cis*- and *trans*-isomerides respectively), with 2 : 4 : 5 : 2′ : 4′ : 5′-*hexamethyldiphenyldicarboxylic acid*, a microcrystalline powder, m. p. 284—285°, which is turned yellow by light. This acid when oxidised in alkaline solution by potassium permanganate is converted into *diphenyl*-2 : 4 : 5 : 2′ : 4′ : 5′ : ? : ?′-*octacarboxylic acid*, a hygroscopic solid which gives a fluorescein reaction when fused with resorcinol ; *calcium* salt, very soluble ; *silver* salt, colourless ; when dried at 110°, the acid loses carbon dioxide and water, giving the *monoanhydride* of *diphenylhexacarboxylic acid*, $C_{12}H_4(CO_2H)_4 <^{CO}_{CO}> O$; the *silver* salt was prepared.

3 : 4 : 5 : 3′ : 4′ : 5′-Hexamethyldiphenyl was prepared from 5-aminohemimellithene (Noelting and Forel, A., 1886, 58 ; Limpach, A., 1888, 464); in the preparation of this latter substance by heating a mixture of *s*-xylidine hydrochloride and methyl alcohol at 250—260° under 30—33 atmospheres' pressure, a relatively large quantity of acridine bases was obtained as a high boiling, feebly basic mixture, which gave fluorescent solutions in organic solvents ; there could be isolated from this mixture a *substance*, m. p. 223°, another substance (probably *tetramethylacridine*), m. p. 172—175°, and a *hexamethylacridine*, m. p. 220—225°; *hydrochloride*, yellow ; *platinichloride*, yellow and sparingly soluble. Aminohemimellithene was converted through the corresponding diazonium salt into 5-*iodohemimellithene*, crystals, m. p. 35°, which on heating with finely divided copper (compare Ullmann, A., 1904, i, 725) at 230—250°, loses iodine with the formation of 3 : 4 : 5 : 3′ : 4′ : 5′-*hexamethyldiphenyl*, m. p. 132—133°. In an experiment on a small scale, in which hexamethyldiphenyl and oxalyl chloride were kept for six weeks in carbon disulphide solution in contact with aluminium chloride, the product was a mixture of carboxylic acids with a neutral yellow *substance*, doubtless the expected 1 : 2 : 3 : 6 : 7 : 8-hexamethylphenanthra-9 : 10-quinone.

In extension of the earlier result with phthalic acid which was converted by acetyl chloride into phthalyl chloride (Liebermann, A.,

1912, i, 464), it is found that terephthalic and *iso*phthalic acids in like manner with acetyl chloride at 130° give *terephthalyl chloride*, needles or leaflets, m. p 83—84° (compare Schreder, this Journ., 1874, 990), and *iso*phtha*lyl chloride*, prisms, m. p. 43—44°, respectively; in the former case the product is accompanied by a little *terephthalyl acid chloride*, $C_6H_4 \cdot COCl \cdot CO_2H$, needles, m. p. above 300°.   D. F. T.

Compounds of Benzaldehyde and Benzonitrile with Antimony Trichloride and Tribromide. BORIS N. MENSCHUTKIN (*J. Russ Phys. Chem Soc*, 1912, **44**, 1929—1938. Compare A., 1912, ii, 920, and *ante*)—For benzaldehyde, Haase (A., 1893, ii, 357) gave the m. p. − 26°, and Altschul and von Schneider (A., 1895, ii, 206) − 13·5°. The author finds that different preparations of the aldehyde melt at temperatures varying from − 26° to − 15°. This behaviour is probably due to the ready oxidisability of the aldehyde in the air, most samples containing dissolved peroxide and acid. With the systems containing benzaldehyde, difficulties were encountered in determining temperatures lying between the melting point of the aldehyde and the first eutectic point.
Benzaldehyde and antimony trichloride form the compound
$$SbCl_3,Ph \cdot CHO,$$
m. p. 43·5°, crystallising in elongated plates, often united in stellar aggregates. The eutectic point between this compound and the pure trichloride lies at 25°, and corresponds with the composition
$$SbCl_3,0 \cdot 44Ph \cdot CHO.$$
The compound $SbBr_3,Ph \cdot CHO$ forms rhombic plates and crystals resembling rhombohedra, m. p. 41·5°, and the eutectic point,
$$SbBr_3,Ph \cdot CHO-SbBr_3,$$
lies at 37·8°, and corresponds with the composition
$$SbBr_3,0 \cdot 63Ph \cdot CHO.$$
Benzonitrile has m. p. − 13·2° (Hofmann, *Jahresbericht*, 1862, 335, gave − 17°, and von Schneider, A., 1896, ii, 290, and 1897, ii, 304, − 12·9°).

The compound $SbCl_3,Ph \cdot CN$ crystallises in quadratic plates, m. p. 21·5°, and the eutectic temperatures and compositions of the system are (1) for $Ph \cdot CN-SbCl_3,Ph \cdot CN$, − 19° and $SbCl_3,10 \cdot 6Ph \cdot CN$, and (2) for $SbCl_3,Ph \cdot CN-SbCl_3$, − 15° and $SbCl_3,0 \cdot 59Ph \cdot CN$.

The compound $SbBr_3,Ph \cdot CN$ forms long plates or needles, m. p. 38°, and the eutectic points are 18° for $SbBr_3,8 \cdot 7Ph \cdot CN$ and 35° for
$$SbBr_3,0 \cdot 74Ph \cdot CN.$$
The diagrams of all the above systems have the form typical of the formation from the components of a single stable compound.   T. H. P.

New Synthesis of Syringaldehyde. FERDINAND MAUTHNER (*Annalen*, 1913, **395**, 273—281).—Syringaldehyde is readily obtained in good yield by Guyot's process (A., 1909, i, 935; 1910, i, 40) A mixture of pyrogallol 1 : 3-dimethyl ether, ethyl mesoxalate, anhydrous zinc chloride, and a little carbamide is kept in glacial acetic acid for fourteen days, whereby *ethyl 4-hydroxy-3 : 5-dimethoxyphenyltartronate*, $OH \cdot C_6H_2(OMe)_2 \cdot C(CO_2Et)_2 \cdot OH$, m. p. 60°, is obtained in almost

quantitative yield. The ester, by hydrolysis by boiling aqueous potassium hydroxide, acidification below 10°, and treatment with aqueous copper sulphate finally at the b. p., is converted into 4-*hydroxy*-3 : 5-*dimethoxyphenylglyoxylic acid* (*syringoylcarboxylic acid*),

$$OH \cdot C_6H_2(OMe)_2 \cdot CO \cdot CO_2H,$$
m. p. 128—129°, yellow needles (p-*nitrophenylhydrazone*, m. p. 225° [decomp.], yellow needles), which yields syringaldehyde by treatment with boiling dimethyl-*p*-toluidine as in Guyot's method. The relative positions of the aldehydo- and hydroxyl groups in the aldehyde are proved by the fact that it yields gallaldehyde trimethyl ether by treatment with methyl sulphate in alkaline solution.

Syringaldehyde forms a p-*nitrophenylhydrazone*, m. p. 216—217°, yellow needles, and an *aldazine*, $C_9H_{12}O_3N_2$, m. p. 208—209°, yellow needles, and reacts with 1-phenyl-3-methyl-5-pyrazolone in hot glacial acetic acid to form 1-*phenyl*-4-p-*hydroxydi*-m-*methoxybenzylidene*-3-*methyl*-5-*pyrazolone*, $C_{19}H_{18}O_4N_2$, m. p. 208—209°, red leaflets, with acetophenone and 33% sodium hydroxide in alcohol at 80° to form, after acidification, 4-*hydroxy*-3 : 5-*dimethoxybenzylidenebisacetophenone*, $C_{25}H_{24}O_5$, m. p. 112—113°, faintly yellow leaflets, and with β-naphthylamine and pyruvic acid in boiling alcohol to form a-p *hydroxydi*-m-*methoxyphenyl*-β-*naphthacinchonic acid*, $C_{22}H_{17}O_5N$, m. p. 275° (decomp.), yellow needles.   C. S.

a-Chloro*cyclo*pentanone and its Derivatives. MARCEL GODCHOT and FÉLIX TABOURY (*Compt. rend.*, 1913, **156**, 332—334).—By passing dry chlorine over *cyclo*pentanone kept at a temperature below 25°, a mixture of substances is obtained, which on fractionation yields 2-*chloro*cyclo*pentanone*, C_5H_7OCl, b. p. 80°/10 mm., D_{14} 1·870, n_D^{14} 1·4782, which on boiling with water or an aqueous suspension of barium carbonate is converted into cyclo*pentanone*-2-*ol*, $C_5H_8O_2$, b. p. 80°/12 mm, D 1·1680. It is very soluble in water, and in solution gives a reddish-brown colour with potassium hydroxide and a violet-red with ferric chloride. It forms a *phenylhydrazone*, yellow needles, m. p. 142—143°, and a *semicarbazone*, a yellow powder decomposing at 170°. This hydroxy-ketone is readily oxidised by 1% potassium permanganate to glutaric acid.

On distilling 2-chloro*cyclo*pentanone either alone or, better, with diethylaniline, it loses hydrogen chloride and is converted into Δ^2-*cyclo*pentenone, a colourless liquid, b. p. 135—136°, which gives a *semicarbazone*, m. p. 214—215°, and an *oxime*, m. p. 52—53°.
                                                                    W. G.

Terpenes and Ethereal Oils. CXIII. Autoreduction of Hydroaromatic Compounds at the Moment of their Formation. OTTO WALLACH and PAUL FRY (*Annalen*, 1913, **395**, 74—86).—β-Methyl-Δ^β-hepten-ζ-one and zinc chloride form at the ordinary temperature after two to three weeks a very viscous, brown mass which is probably an additive compound, since it is decomposed into its generators by water. At 100°, however, methylheptenone reacts vigorously in the presence of zinc chloride or phosphoric oxide; hydrogen is not evolved and the product is a complex mixture from

which an oil is obtained by distillation with steam. By distillation this oil yields a very large fraction, b. p. 130—140°, which is not 1 : 3 dimethyl*cyclo*-Δ^1 ^{3}-hexadiene as stated previously, but is proved to be a mixture of *m*-xylene and 1 : 3-dimethyl-Δ^1-*cyclo*hexene by treatment with 3% potassium permanganate at 0°, whereby the *m*-xylene is unattacked, whilst the 1 : 3-dimethyl*cyclo*hexene is converted into 1 : 3-*dimethylcyclohexane*-3 : 4-*diol*, $OH \cdot CMe < ^{CH(OH) \cdot CH_2}_{CH_2 - CHMe} > CH_3$, m. p. 89°. The constitution of the glycol is proved by the fact that it yields 1 : 3-dimethyl*cyclo*hexan-4-one, b. p. 179—179·5°, D^{21} 0 9066, n_D^{21} 1·4464 (*semicarbazone*, m. p. 189° ; *oxime*, m. p. 98—99°), by treatment with warm dilute sulphuric acid. This ketone in an impure state (b. p. 176 5°, D^{16} 0·9124, n_D 1·446) has been described by Sabatier and Mailhe, in 1906. By oxidation with chromic and dilute sulphuric acids on the water-bath, it yields a keto-acid (*semicarbazone*, m. p. 136—137°), which is converted into bromoform and β-methyladipic acid by alkaline hypobromite.

Since hydrogen is not evolved and 1 : 3-dimethyl-Δ^1 ^{3}-*cyclo*hexadiene is not obtained by the auto-condensation of the methylheptenone, it follows that one molecule of 1 : 3-dimethyl*cyclo*hexadiene loses hydrogen and changes to *m*-xylene, the hydrogen converting a second molecule into 1 : 3-dimethyl*cyclo*-Δ^3-hexene.   C. S.

Synthetic *p*-Dialkylated Dihydroxyquinones and Hydroxy-perezone. Fritz Fichter, Max Jetzer, and Robert Leepin (*Annalen*, 1913, **395**, 1—25. Compare A., 1904, i, 678 ; 1908, i, 658).—The following substances have been prepared by the reaction, as described previously, between sodium, ethyl oxalate, and a fatty ester in ether or benzene. The reaction proceeds more slowly the greater the molecular weight of the fatty acid, and reaches its limit with *n*-decoic ester ; ethyl laurate or palmitate do not yield a *p*-dialkylated dihydroxy-quinone. 3 : 6-*Dihydroxy*-2 : 5-*diisobutyl-p-benzoquinone*, $C_{14}H_{20}O_4$, m. p. 217—218° (in closed tube), red spangles (*diacetate*, m. p. 113·5°, yellow crystals), from ethyl *iso*hexoate, develops a blue coloration in concentrated sulphuric acid and a violet in aqueous sodium hydroxide. 3 : 6-*Dihydroxy*-2 : 5-*diamyl-p-benzoquinone*, $C_{16}H_{24}O_4$, m. p. 164°, red leaflets (*diacetate*, m. p. 74°, yellow needles), from ethyl *n*-heptoate ; 3 : 6-*dihydroxy*-2 : 5-*dihexyl-p-benzoquinone*, $C_{18}H_{28}O_4$, m. p. 154°, red scales (*diacetate*, m. p. 68°, yellow needles), from ethyl *n*-octoate ; 3 : 6-*dihydroxy*-2 : 5-*diheptyl-p-benzoquinone*, $C_{20}H_{32}O_4$, m. p. 145°, red leaflets (*diacetate*, m. p. 77·5°, yellow needles), from ethyl *n*-nonoate ; 3 : 6-*dihydroxy*-2 : 5-*dioctyl-p-benzoquinone*, m. p. 141°, red leaflets, from ethyl *n*-decoate. In the colour of their solutions and of their alkali salts, and in their inactivity towards hydroxylamine and ortho-diamines, *p*-dialkylated dihydroxybenzoquinones show a greater similarity to chloroanilic acid than to the unsubstituted dihydroxybenzoquinone. The same is true of their ethers ; 3 : 6-*dimethoxy*-2 : 5-*diisopropyl-p-benzoquinone*, $CPr^\beta < ^{C(OMe) \cdot CO}_{CO \cdot C(OMe)} > CPr^\beta$, m. p. 142°, prepared from the silver derivative, crystallises in almost black leaflets.

Ethyl iso*valerylacetate*, $CH_2Pr^\beta \cdot CO \cdot CH_2 \cdot CO_2Et$, b. p. 99·5°/12·5 mm.,
D^{15} 0·964, prepared by hydrolysing ethyl *iso*valerylacetoacetate with
aqueous ammonia, is soluble in alkalis, develops an intense red colora-
tion with ferric chloride, yields 1-*phenyl*-3-iso*butyl*-5-*pyrazolone*,

$$CH_2Pr^\beta \cdot C \underset{N---NPh}{\overset{CH_2 \cdot CO}{<}},$$
m. p. 105·5°, with phenylhydrazine, and condenses with resorcinol and
concentrated sulphuric acid to form 5-*hydroxy*-4-iso*butylcoumarin*,
$C_{13}H_{14}O_3$, m. p. 117°, glistening needles, which dissolves in alkalis with
a blue fluorescence.

By treatment with ozonised oxygen, 3 : 6-dihydroxy-2 : 5-dialkyl-
p-benzoquinones in dry chloroform at 0° do not yield ozonides,
but are decomposed in the sense of the equation :

$$C_6R_2(OH)_2O_2 + 6O + 2H_2O = 2H_2C_2O_4 + 2R \cdot CO_2H,$$
the necessary water being produced by the complete oxidation of
a portion of the quinone ; thus dihydroxydi*iso*propyl-*p*-benzoquinone
yields oxalic and *iso*butyric acids, dihydroxy-*p*-xyloquinone yields oxalic
and acetic acids (the same products are also obtained by the oxidation
of the quinone by alkaline potassium permanganate), dihydroxy-
diethyl-*p*-benzoquinone yields oxalic and propionic acids, and dihydroxy-
thymoquinone yields oxalic and *iso*butyric acids, acetic acid not being
detected.

The study of dialkylated dihydroxybenzoquinones has thrown con-
siderable light on the constitution of perezone (pipitzahoic acid). This sub-
stance is converted through the anilino-derivative into hydroxyperezone
by Mylius's method (A , 1885, 777, 805). Hydroxyperezone, $C_{15}H_{20}O_4$,
m. p. 138—139°, yellowish-red needles, resembles the dialkylated
dihydroxy-*p*-benzoquinones in its colour, in the colorations it develops
with concentrated sulphuric acid and with aqueous sodium hydroxide
respectively, and in its conversion into a *tetra-acetate*, $C_{23}H_{30}O_8$, m. p.
97—98°, colourless crystals, by reductive acetylation. By treatment
in chloroform with ozonised oxygen, it yields oxalic acid and not
a volatile fatty acid as expected, but $\alpha\beta$-diketobutyric acid, which is
isolated and identified by treating its aqueous solution with phenyl-
hydrazine, whereby $\alpha\beta$-diketobutyric acid phenylosazone (completely
identified by its conversion by warm alkali into 4-benzeneazo-1-phenyl-
3-methyl-5-pyrazolone) is obtained. The formation of the diketo-
butyric acid is accounted for if one of the side-chains in hydroxy-
perezone is a propenyl group. Consequently, the other side-chain must
be a hexyl group, since the sum of the carbon atoms in the side-chains
is 9. Hydroxyperezone, therefore, has the constitution

$$C_6H_{13} \cdot C \underset{CO \cdot C(OH)}{\overset{C(OH) \cdot CO}{<}} > C \cdot CH{:}CHMe.$$
Since hydroxyperezone readily loses water to form perezinone (Mylius,
loc. cit.), whilst perezone does not suffer an analogous change, perezone
has the constitution $C_6H_{13} \cdot C \underset{CO---CH}{\overset{C(OH) \cdot CO}{<}} > C \cdot CH{:}CHMe$, and pere-
zinone is $\underset{C(C_6H_{13}) \cdot CO \cdot C \cdot CH_2}{\overset{C(OH)---CO \cdot C---CH}{|}} > CH.$ By reduction with sodium
amalgam and aqueous sodium hydroxide at 100°, hydroxyperezone yields

hexylpropenyldihydroresorcinol, $C_{15}H_{24}O_2$, m. p. 140—144°, colourless needles. By similar treatment, dihydroxythymoquinone yields *methyl-isopropyldihydroresorcinol*, $C_{10}H_{16}O_2$, m. p. 170°, softening at 145°, colourless leaflets. C. S.

Camphor and its Derivatives. XII. JULIUS BREDT (*Annalen*, 1913, **395**, 26—63).—[With J. HOUBEN, P. LEVY, and S. LINK.]—

Methyl 4-chlorocamphorate, $\begin{matrix} CH_2-CCl(CO_2Me) \\ CH_2 \cdot CMe(CO_2Me) \end{matrix} > CMe_2$, m. p. 56°, b. p.

158°/15 mm., is prepared from 4-chlorocamphoryl chloride and sodium methoxide in methyl alcohol. By slow distillation at 254—285° under ordinary pressure, it yields hydrogen chloride and *methyl dehydro-camphorate*, $C_{12}H_{18}O_4$, b. p. 137°/15 mm., and also methyl chloride and methyl camphanate, the latter decomposition resembling that which occurs during the distillation of the ester of a γ-halogenated fatty acid. *Phenyl 4-chlorocamphorate*, $C_{22}H_{25}O_4Cl$, m. p. 89°, obtained in a similar manner from sodium phenoxide in petroleum (b. p. 70—100°), yields, by slow distillation or by heating with quinoline, only hydrogen chloride and *phenyl dehydrocamphorate*, $C_{22}H_{22}O_4$, m. p. 155°. *Phenyl dl-4-chloro-camphorate*, m. p. 74°, yields *phenyl* dl-*dehydrocamphorate*, m. p. 133°, by similar treatment.

By hydrolysis with aqueous methyl alcoholic potassium hydroxide, removal of the alcohol and phenol, and subsequent acidification, phenyl dehydrocamphorate yields *d*-dehydrocamphoric acid, m. p. 202—203°,

$[α]_D^{21}$ +118·6° in chloroform and +113·8° in alcohol, which is converted into iso*dehydrocamphoric an-hydride* (annexed formula), m. p. 185·5—186°, and camphonenic acid by distillation under ordinary pressure. iso*Dehydrocamphoric acid* has m. p. 181—182°, and readily yields the anhydride by treatment with cold acetyl chloride. Dehydrocamphoric acid yields camphoronic acid by oxidation with dilute nitric acid or alkaline potassium permanganate, and forms a *methyl hydrogen* ester, $C_{11}H_{16}O_4$, m. p. 96°, *silver* salt, $C_8H_{12}(CO_2Ag)_2,H_2O$, and *calcium* salt, $C_{10}H_{12}O_4Ca,4H_2O$.

It does not form an anhydride, and yields the *chloride*, $C_{10}H_{12}O_2Cl_2$, b. p. 139°/13·5 mm., m. p. about 50°, by treatment with phosphorus pentachloride or acetyl chloride. The non-formation of an anhydride and the fact that its chloride reacts with aqueous ammonia at 0° to form the *diamide*, $C_{10}H_{16}O_2N_2,H_2O$, m. p. 191°, colourless needles (compare A., 1912, i, 411), show that dehydrocamphoric acid has something approaching the *cis-trans* configuration. Reference to the tetrahedral model shows that the two carboxyl groups are in what the author terms the *meso-trans* position, in which the spatial separation of the acidic groups is almost as great as in the *cis-trans* modification of the isomeric iso*dehydrocamphoric acid*.

The non-existence of dehydrocamphoric anhydride explains why hydrogen chloride or bromide cannot be eliminated from the C_5-ring of 4-chloro- or bromo-camphoric anhydride.

With S. LINK and TH. FUSSGÄNGER.]—When heated at 100° for

six hours with hydrobromic acid saturated at 0°, *d*-dehydrocamphoric acid yields a mixture of cis-3-*bromocamphoric acid*, m. p. 158—160°, and trans-3-*bromocamphoric acid*, m. p. 232°, of which the former is easily soluble in benzene. The *cis*-acid, which is the chief product of the action of hydrobromic acid at 0°, yields *cis*-camphoric acid, and the *trans*-acid yields *trans*-camphoric acid, by reduction with zinc and glacial acetic and 24% hydrochloric acids. The action of hydrobromic acid at 100° on *dl*-dehydrocamphoric acid yields a mixture of two stereoisomeric dl-3-*bromocamphoric acids*, m. p. 188—189° (decomp.) and 239—240° respectively, of which the less fusible is the chief product, is insoluble in benzene, and yields *trans-dl*-camphoric acid by reduction. Unlike the active acid, *dl*-dehydrocamphoric acid is not attacked by hydrobromic acid at 0°, even after three months.

By boiling with aqueous sodium carbonate and subsequently acidifying, *cis*-3-bromocamphoric acid yields 3-*hydroxycamphorolactone*, $C_{10}H_{14}O_4$, m. p. 228°, whilst *trans*-3-bromocamphoric acid yields trans-3-*hydroxycamphoric acid*, $C_{10}H_{16}O_5$, m. p. 194°, and camphonenic acid, m. p. 155°, identical with that mentioned above and with the un-saturated acid obtained by Noyes from the nitroso-derivative of aminolauronolic anhydride (A., 1906, i, 397). The constitution of camphonenic acid is proved by the formation of camphoronic acid by oxidation with nitric acid or potassium permanganate.

3-Hydroxycamphorolactone boils unchanged, but *trans*-3-hydroxycamphoric acid yields dehydrocamphoric acid and *iso*dehydrocamphoric anhydride by slow distillation. *trans*-3-Hydroxycamphoric anhydride yields only the latter by distillation.

By heating equal molecular quantities of bromine and dehydro-camphoryl chloride at 100° for six hours, decomposing the product with aqueous sodium carbonate, and acidifying, an unsaturated *acid*, $C_9H_{12}O_2$, m. p. 149°, colourless needles, is obtained, which is probably *dehydrolaurolenic acid*.

From the behaviour of the two acids, it is probable that in *cis*-3-bromocamphoric acid the two carboxyl groups are each in the *cis*-position to the bromine atom, whilst in *trans*-3-bromocamphoric acid the bromine is in the *cis*-position to the neighbouring carboxyl and in the trans-position to the other carboxyl group, because lactone formation does not occur by the distillation of its esters, although the halogen is in the γ-position to the carboxyl group.   C. S.

Action of Magnesium and Allyl Haloids on Camphor. METSCHISLAV CHOJN (*J. Russ. Phys. Chem. Soc.* 1912, 44, 1844—1853). —*Allylborneol* (1 : 7 : 7-*trimethyl*-2-*allyl*-1 : 2 : 2-bicyclo*heptan*-2-*ol*),
$$CH_2 \cdot CH = CH_2$$
$$| \quad CMe_2 |$$
$$CH_2 \cdot CMe \cdot C(OH) \cdot CH_2 \cdot CH{:}CH_2,$$

obtained by decomposing with water the product of the interaction of magnesium, allyl bromide or iodide, and camphor, is a colourless, viscous liquid with a pleasant camphor-like odour, b. p. 118—119°/17 mm., 120—121°/21 mm., D_4^{18} 0·9474, n_D^{18} 1·48943, and exhibits the normal molecular weight in freezing benzene or boiling ether. It

unites with two atoms of bromine and, when treated in ethereal solution and in presence of anhydrous sodium sulphate with dry hydrogen chloride at 0°, gives the analogous chloro-derivative, which is converted into the corresponding unsaturated hydrocarbon when heated with dry pyridine.

Oxidation of allylborneol with 1% potassium permanganate solution yields *βγ-dihydroxypropylborneol* (1 : 7 : 7-*trimethyl-2-propan-βγ-diol-*

$$CH_2 \cdot \overset{|}{C}H-CH_2$$

1 : 2 : 2-bicyclo*heptan*-2-*ol*), $\overset{|}{C}Me_2 \overset{|}{}$,

$$CH_2 \cdot CMe \cdot C(OH) \cdot CH_2 \cdot CH(OH) \cdot CH_2 \cdot OH$$
which forms radiating or beard-like masses of tasteless, odourless, snow-white crystals, m. p. 119—120°, and exhibits normal ebullioscopic behaviour in benzene.
When oxidised with 4% potassium permanganate (4 atoms of oxygen), allylborneol is converted into the hydroxy-acid, *borneolacetic*

$$CH_2 \cdot \overset{|}{C}H-CH_2$$

acid, $\overset{|}{C}Me_2 \overset{|}{}$, which was not obtained in the

$$CH_2 \cdot CMe \cdot C(OH) \cdot CH_2 \cdot CO_2H$$

pure state; the *ammonium*, *silver*, and *calcium* ($+2H_2O$) salts of the acid were prepared and analysed.   T. H. P.

Bupleurol. The Alcohol from the Essential Oil of Bupleurum fructicosum. LUIGI FRANCESCONI and E. SERNAGIOTTO (*Atti R. Accad. Lincei*, 1913, [v], 22, i, 34—40).—This alcohol, which the authors named *bupleurol*, can be isolated by the aid of phthalic anhydride from the higher fractions of the essential oil. It has the composition $C_{10}H_{20}O$, b. p. 209—210°/762 mm., D^{17} 0 8490, n_D 1·4508, and is optically inactive; the substance has a slight, pleasant odour of roses. From its physical properties the substance is probably an olefinic alcohol, and this is supported by the fact that it yields an oily *dibromide*. It forms a *urethane*, which crystallises in lustrous needles, m. p. 45°. Oxidation of bupleurol with chromic acid yields: (1) an *aldehyde*, which shows Schiff's reaction, and gives a *semicarbazone*, m. p. 135°; (2) an *aldehyde*, of which the *semicarbazone* has m. p. 97°; (3) a *ketone* (b. p. 217°, n_D^{25} 1·4419), which yields a *semicarbazone*, m. p. 189—190°; (4) a red oil, b. p. 207°, which is the *ester* of bupleurol and the corresponding *acid*, which was also isolated. Bupleurol is isomeric with citronellol and with androl, and the authors assign to it the formula $CHMe_2 \cdot [CH_2]_3 \cdot C(CH_2) \cdot CH_2 \cdot CH_2 \cdot OH$, which is that of a dihydro-derivative of nerol.

When the *phthalic* ester of bupleurol is dissolved in ammonia and treated with silver nitrate, the *silver* salt, $C_{18}H_{28}O_4Ag$, is obtained, m. p. 135°.

In the isolation of bupleurol, a *substance*, $C_{10}H_{16}O$, is also met with; it has an acrid odour, gives a coloration with Schiff's reagent, reduces ammoniacal silver nitrate, and has D 0·9264, $[a]_D$ 14·93°, n_D 1·4909.
                                               R. V. S.

Insoluble Constituents of Ceara- and Rambong-Caout-chouc. CLAYTON BEADLE and HENRY P. STEVENS (*Zeitsch. Chem. Ind.*

Kolloide, 1913, 12, 46—48).—The influence of the insoluble constituents on the properties of Ceara- and Rambong-caoutchouc has been investigated, and the results compared with those of similar experiments carried out previously with Hevea-caoutchouc (A., 1912, i, 789). "Benzine" was added to the caoutchouc, and the products recovered from the upper clear solution and the lower turbid solution were separately examined, the latter containing practically the whole of the insoluble constituent. The data compared are the nitrogen content, the proportion of free and fixed sulphur in the vulcanised material, and the mechanical properties. Although the relationships involved are of a complicated character, it would appear that the insoluble constituents play an important part in connexion with the vulcanisation of the caoutchouc, and are more or less independent of the percentage content of nitrogenous substances in the caoutchouc.   H. M. D.

Artificial Caoutchoucs. II. CARL D. HARRIES (*Annalen*, 1913, 395, 211—264).—Replies are given to the remarks of Lebedev (A., 1911, i, 959), Kondakov, Ostromisslenski, and Perkin (A., 1912, i, 636) in connexion with the author's first paper (A, 1911, i, 798).

[With MAX HAGEDORN.]—The identity of natural and of artificial caoutchoucs cannot be satisfactorily tested by a comparison of their derivatives except in the case of the ozonides. The products of their decomposition contain similar amounts of lævualdehyde and its acid and diperoxide. Also the comparison of the velocity of decomposition, under proper conditions, of the diozonides and dioxozonides (Harries and Neymann, A., 1908, i, 967; Harries, A., 1912, i, 706) gives satisfactory results. The decomposition curves of the diozonides of Para caoutchouc (purified by twice precipitating its benzene solution by alcohol, and by two extractions with acetone in a Soxhlet apparatus for twelve hours), of gutta-percha, and of artificial caoutchouc obtained by the autopolymerisation of isoprene at 95°, are the same; the decomposition curve of artificial caoutchouc, obtained from isoprene by the acetic acid process, is slightly different. The decomposition curve of "sodium" caoutchouc diozonide is quite different. The same is true of the butadiene caoutchoucs. "Sodium" butadiene-caoutchouc (purified by the alcohol-benzene method) forms a diozonide, the decomposition products of which do not contain a trace of succindialdehyde or lævulaldehyde, and the decomposition curve of which is quite different from that of the diozonide of butadiene-caoutchouc polymerised by heat.

Like natural caoutchouc, artificial "normal" caoutchoucs form diozonides and dioxozonides. Artificial "sodium" caoutchoucs also form diozonides and dioxozonides, although with greater difficulty; the products of their decomposition by water are similar, but the diozonides yield a larger proportion of aldehydes, the dioxozonides a larger amount of acids.

Gutta-percha, purified by alcohol and chloroform and by prolonged extraction with acetone, yields, with washed 9—10% ozone, a *diozonide*, $C_{10}H_{16}O_6$, which so closely resembles the diozonide of natural or of artificial caoutchouc that most probably they are identical. By further treatment with 18% ozone in chloroform, gutta-percha diozonide yields

a *dioxozonide*, $C_{10}H_{16}O_8$, which behaves like the dioxozonide of Para caoutchouc.

The authors have been able to account for a phenomenon which has frequently been observed. Caoutchouc diozonides, prepared apparently in the same manner, frequently yield, by decomposition with water, different amounts of the crystalline lævulaldehyde diperoxide, m. p. 196°; it has now been shown that the quantity of this product increases with amount of dioxozonide in the diozonide.
In partial agreement with Gottlob (A., 1908, i, 436), the authors find that the diozonides of African (Congo) caoutchoucs yield quantities of decomposition products distinctly different from those of the decomposition products of the diozonides of Para caoutchouc, artificial caoutchouc, and gutta-percha. Congo caoutchoucs yield dioxozonides only with difficulty.

[With WILHELM SCHONBERG.]—The exhaustive methylation of piperidine is not a suitable method for the preparation of piperylene in quantity. It can be obtained readily as follows: (1) acraldehyde and magnesium ethyl bromide yield by the usual process the alcohol, CH_2:$CH\cdot CHEt\cdot OH$, which is then dehydrated by phthalic anhydride; (2) the alcohol, $CHEt_2\cdot OH$, prepared in the usual manner from ethyl formate and magnesium ethyl bromide, yields Δ^β-pentene by distillation with phosphoric oxide; the olefine forms a *dibromide*,

$$CHMeBr\cdot CHEtBr,$$

b. p. 65—70°/15 mm., which is converted into piperylene by the sodium carbonate process at about 600°. This is the best method.

By heating for about fourteen days at 105—110° in an atmosphere of carbon dioxide, piperylene polymerises to "normal" *piperylene-caoutchouc*, $C_{10}H_{16}$, which is elastic and very closely resembles "normal" isoprene-caoutchouc in most of its properties. It forms a *nitrosite-a*, $C_{10}H_{16}O_5N_2$ (?), decomp. 118—122°, yellow powder, insoluble in acetone or ethyl acetate, and a *nitrosite-c*, $2C_{10}H_{15}O_7N_3$, decomp., 162—164°, easily soluble in acetone or ethyl acetate, and an unstable *bromide*, $C_{10}H_{15}Br_3$ (?), decomp. 150—160°, pale yellow, amorphous powder; these three derivatives are almost indistinguishable from the corresponding derivatives of "normal" isoprene-caoutchouc. The ozonides of the two caoutchoucs, however, are quite dissimilar. By treatment with washed ozone in chloroform, piperylene-caoutchouc yields the *diozonide*, $C_{10}H_{16}O_6$, which explodes violently by heating, and exhibits the usual properties of ozonides. It forms a dioxozonide only with very great difficulty. The decomposition curve of piperylene-caoutchouc diozonide is similar to, yet quite distinct from, that of normal caoutchouc diozonide, but the decomposition products are quite different. The former diozonide does not yield lævulaldehyde, but a substance which is most probably methylsuccindialdehyde. Hence "normal" piperylene-caoutchouc (which is a true structural isomeride of "normal" caoutchouc, piperylene being $\Delta^{\alpha\gamma}$-pentadiene) is a derivative of 1:5-dimethyl-2:6-*cyclo*octadiene,

$$2CHMe\text{:}CH\cdot CH\text{:}CH_2 \longrightarrow \begin{matrix} CHMe\cdot CH\text{:}CH\cdot CH_2 \\ CH_2-CH\text{:}CH-CHMe \end{matrix} \longrightarrow$$
$$2CHO\cdot CH_2\cdot CHMe\cdot CHO.$$

During the polymerisation of piperylene by heating, a by-product is obtained in the form of a *terpene*, $C_{10}H_{16}$, b. p. 58—59°/11 mm., $D_1^{20\cdot5}$ 0·8313, $n_D^{20\cdot5}$ 1·46916, n_α 1·46620, n_γ 1·48373, which forms a crystalline *bromide*, m. p. 178°, and a white *diozonide*, $C_{10}H_{16}O_6$; the velocity of decomposition of the latter by water at 125° is very great, but definite substances could not be isolated from the products owing to lack of material.

The polymerisation of piperylene by sodium at 60° yields a "sodium" piperylene-caoutchouc which is brittle after purification; it forms a *nitrosite*, decomp. 140—145°, and a *bromide*, the analyses of which do not correspond with the formulæ of the normal compounds.

[By the AUTHOR.]—The proof of the presence of an 8-ring in "normal" caoutchoucs is of fundamental importance in the chemistry of caoutchoucs. To test this point, the velocity of decomposition of "normal" butadiene-caoutchouc diozonide has been compared with that of the diozonide of Willstätter's 1 : 5-*cyclo*octadiene. (A serious difficulty is encountered in separating the "normal" butadiene-caoutchouc from the terpenoid hydrocarbon, C_8H_{12}, obtained as a by-product during the polymerisation. Both substances form almost colourless *diozonides*, $C_8H_{12}O_6$; the diozonide of the terpenoid hydrocarbon is decomposed very rapidly by water at 125°, and the products of decomposition contain hydrogen peroxide, but do not respond to the pyrrole test.) The comparison shows that both decompose at the same rate ·(at first the "normal" butadiene-caoutchouc decomposes more rapidly, but this is probably due to the presence of a little of the easily decomposable diozonide of the terpenoid hydrocarbon), and yield practically the same amount of succindialdehyde. Since the decomposition curve of 1 : 5-*cyclo*octadiene diozonide is very characteristic, and since the decomposition products of the two diozonides are quite alike in not responding to the hydrogen peroxide test and in containing the same percentage of succindialdehyde, the statement is made with considerable confidence that "normal" caoutchoucs contain an 8-ring.

[With RICHARD SEITZ.]—Although Zelinsky and Gorsky (A., 1908, i, 619) have resolved 1-methyl-$\Delta^{2:4}$-*cyclo*hexadiene into its active forms, their method of preparing the substance does not necessarily lead to the formation of a compound of this constitution (compare Harries and Neymann, A., 1909, i, 218). The authors, therefore, have used a method similar to that by which Harries obtained pure $\Delta^{1:3}$-*cyclo*hexadiene (A., 1912, i, 343). 1-Methyl-Δ^3-*cyclo*hexene and bromine in acetic acid yield 3 : 4-*dibromo*-1-*methyl*cyclohexane, b. p. 94—95°/12 mm., which reacts with 33% alcoholic trimethylamine (2 mols.) at about 95° for twenty hours to form 1-*methyl*-Δ^1-*cyclo*hexenyl-3-trimethylammonium bromide or 1-*methyl*-Δ^3-cyclohexenyl-4-trimethylammonium bromide, $C_{10}H_{20}NBr$, m. p. 166—167°. The bromide, whichever constitution it may have, must yield 1-methyl-$\Delta^{2:4}$-*cyclo*hexadiene by treatment with water and silver oxide and subsequent distillation. The hydrocarbon agrees well in its physical constants (b. p. 100·5—101·5°, D_4^{25} 0·8252, n_α 1·46225, n_β^{25} 1·46619, n_γ 1·48519) with Zelinsky and Gorsky's compound (*loc. cit.*). By treatment with unwashed 18—20% ozone in chloroform, it yields a *diozonide*, $C_7H_{10}O_6$,

which is decomposed in ether by copper hydride, yielding probably methylsuccindialdehyde and glyoxal ; these substances, however, could not be definitely identified. C. S.

Comparative Researches on the Polymerisation Products of βγ-Dimethylbutadiene obtained Spontaneously and by Heat. CARL D. HARRIES (*Annalen*, 1913, **395**, 264—272).—[With MAX HAGEDORN.]—"Normal" βγ-dimethylbutadiene-caoutchouc, produced by heating βγ-dimethylbutadiene in a closed vessel, yields very readily the diozonide and the dioxozonide, both of which are decomposed by water, giving an almost quantitative yield of acetonylacetone. Kondakov's white, insoluble polymeride, produced by the prolonged keeping of βγ-dimethylbutadiene at the ordinary temperature, also readily forms a *diozonide*, $C_{12}H_{20}O_6$, and *dioxozonide*, $C_{12}H_{20}O_8$, by the decomposition of which by water only about 20% of acetonylacetone is produced. Also the decomposition curves of the two diozonides are very different.

By exposure to air for a few hours, Kondakov's polymeride changes to a yellow, soluble resin. This forms a *diozonide*, $C_{12}H_{20}O_6$, and *dioxozonide*, $C_{12}H_{20}O_8$, by the decomposition of which about 36% of acetonylacetone is obtained.

The author is of opinion that Kondakov's polymeride is not a true caoutchouc, and by analogy, therefore, that the caoutchouc obtained by Pickles (T., 1910, **97**, 1085) by the prolonged keeping of isoprene is not true caoutchouc. C. S.

Chlorophyll. LÉON MARCHLEWSKI (*Annalen*, 1913, **395**, 194—210).—A reply to Willstätter and Isler (A., 1912, i, 710). The author maintains his contention that Willstätter's phaeophytin is chlorophyllan under another name The heterogeneity of chlorophyllan was established by the author and Malarski (A., 1909, i, 947) before Willstätter (A., 1911, i, 393).

The proportion of the components *a* and *b* in chlorophyll is determined far more conveniently by Marchlewski and Jacobson's method (A., 1912, ii, 705) than by Willstätter and Isler's process (*loc. cit.*). C. S.

Alkaloids of Aconitum Lycoctonum. HEINRICH SCHULZE and ERICH BIERLING (*Arch. Pharm.*, 1913, **251**, 8—49).—A detailed résumé is first given of the work of Hübschmann (*Schweiz. Woch. Pharm.*, 1865, **3**, 269), Dragendorff and Spohn (A., 1885, 403), Einberg (*Diss. Dorpat.*, 1887), Dohrmann (*ibid.*, 1888), and van der Bellen (*ibid.*, 1890) on these alkaloids. The author's results extend, and to some extent confirm, those of Dragendorff and his pupils. It is shown that the alkaloids of this species differ from the typical " aconitines " in not yielding two monobasic acids on hydrolysis.

The coarsely ground roots were exhausted with 94% alcohol, the extract concentrated, and set aside to deposit sucrose, the mother liquor further concentrated, and diluted with three times its volume of water to separate resin and oil, and the filtrate, after extraction with ether to remove the last traces of oil, made alkaline with sodium

hydroxide and the liberated lycaconitine extracted with ether. The alkaline liquor was then shaken with chloroform, and the amorphous alkaloids so obtained freed from traces of lycaconitine by extraction with ether. This partly purified mixture of alkaloids was dissolved in dilute hydrochloric acid (3%), the solution treated with potassium thiocyanate in excess to remove an alkaloid giving an insoluble thiocyanate, and the filtrate made alkaline with sodium hydroxide and extracted with chloroform, which removed myoctonine.

Lycaconitine, $C_{36}H_{46}O_{10}N_2$, $[a]_D^{20}$ +42·47° in alcohol, was decolorised by means of animal charcoal, and thus obtained as a colourless powder, easily soluble in alcohol or chloroform, less so in ether; it is a weak base from which no crystalline derivatives could be prepared. On hydrolysis by water or dilute hydrochloric acid, it yields succinic acid and anthranoyl-lycoctonine. Alkalis hydrolyse it to lycoctonine and lycoctoninic acid.

Myoctonine, $(C_{36}H_{42}O_{10}N_2)_2$, $[a]_D^{20}$ +44·79° in alcohol, is a colourless, amorphous powder, soluble in alcohol or chloroform, but sparingly so in ether; the solution in alcohol fluoresces bluish-violet. No crystalline derivatives were obtained. On hydrolysis by hydrochloric acid or alkalis, it furnishes the same products as lycaconitine.

The unnamed base giving an insoluble thiocyanate was not analysed; on hydrolysis by alkalis, it also yields lycoctonine and lycoctoninic acid.

Lycoctonine, $C_{25}H_{39}O_7N,H_2O$, m. p. 131—133°, $[a]_D^{20}$ +49·64° in alcohol, crystallises in long, colourless needles from dilute alcohol, is a strong base, contains four methoxyl groups and a methylimino-group, and becomes amorphous when dehydrated by drying at 100°/40 mm. The *hydrochloride*, B,HCl,H_2O, m. p. 75° (decomp.), forms colourless prisms; the *hydrobromide*, $B,HBr,2H_2O$, has m. p. 88—89°, and the *perchlorate*, $B,HClO_4,1\frac{1}{2}H_2O$, m. p. 68—69° (decomp.), forms heavy prisms. The *methiodide*, B,MeI, m. p. 178°, forms pale yellow needles from alcohol on addition of ether, and the *methochloride aurichloride*, $B,Me,HAuCl_4$, small, heavy, yellow prisms. Lycoctonine contains at least two hydroxyl groups.

Lycoctoninic acid, $C_{11}H_{11}O_5N$, m. p. 179°, forms bright brown needles or leaflets from dilute alcohol, and appears to be succinanil-carboxylic acid (Riedel, A., 1912, i, 774).

Anthranoyl lycoctonine, $C_{32}H_{44}O_8N_2$, m. p. 154—155°, forms bright brown, glancing leaflets, is easily soluble in chloroform, but sparingly so in other solvents; the solutions fluoresce bluish-violet. The alkaloid contains four methoxyl groups and a methylimino-group. The *perchlorate*, $B,2HClO_4$, alone was obtained crystalline; it forms aggregates of colourless needles, and does not melt completely even at 235°. On hydrolysis by sodium hydroxide in alcohol, the free base yields lycoctonine and anthranilic acid. Anthranoyl-lycoctonine is probably identical with Dragendorff's "lycaconine," but as it is not analogous with the other "aconines," lycoctonine be'ng the corresponding substance in this instance, it is proposed to abandon this name.

The reactions of these alkaloids with the usual alkaloidal reagents and precipitants are tabulated in the original.

Hildebrandt reports that in doses of 0·01 gram, lycaconitine stills the

frog's heart in five hours and myoctonine in seven hours, death occurring three hours later. Lycoctonine causes paralysis after seven hours, but does not still the heart, whilst the action of the relatively insoluble anthranoyl-lycoctonine only becomes apparent after six days. When paralysis of the heart's action does not come on too quickly, all the alkaloids show the characteristic action of the aconitines on the heart. T. A. H.

ψ-Laudanine. HERMAN DECKER and THEODOR EICHLER (*Annalen*, 1913, **395**, 377—381).—The reduction of an alcoholic solution of *N*-methylnorpapaverinium phenolbetaine (Decker and Dunant, A., 1908, i, 204) by tin and concentrated hydrochloric acid on the water-bath yields the *stannochloride*, $C_{20}H_{25}O_4N,HCl,SnCl_2$, of a *base*, $C_{20}H_{25}O_4N$, m. p. 111°, which has the constitution :
$$C_6H_3(OMe)_2 \cdot CH_2 \cdot CH < ^{C_6H_3(OH)(OMe)}_{NMe\text{———}CH_2} > CH_2,$$
and is called *ψ-laudanine*, since it differs from laudanine only by the interchange in position of a hydroxyl and a methoxyl group. The *hydrochloride*, *platinichloride*, *chromate*, *picrate*, m. p. 162—163°, and *perchlorate* of the base are mentioned. C. S.

Syntheses of Dihydro*iso*quinoline Derivatives. HERMAN DECKER, WALTER KROPP, HEINRICH HOYER, and PAUL BECKER (*Annalen*, 1913, **395**, 299—320. Compare Pictet and Kay, A., 1909, i, 513 ; Decker and Kropp, *ibid.*, i, 513).—Derivatives of 3 : 4-dihydro-*iso*quinoline are obtained by the interaction of acyl-β-phenylethyl-amides and phosphorus pentachloride and phosphoryl chloride in boiling benzene, toluene, or xylene, moisture being carefully excluded. Formo-β-phenylethylamide yields very little 3 : 4-dihydro*iso*quinoline (*picrate*, m. p. 174—176°), the chief products being β-phenylethylamine and β-phenylethylaminomalon-β-phenylethylamide (Decker and Becker, A., 1911, i, 714). Phenylaceto-β-phenylethylamide, treated as in Decker and Kropp's method (*loc. cit.*), yields *di-β-phenylethylamine* (?), $NH(CH_2 \cdot CH_2Ph)_2$, b. p. 220—230°/30 mm. (*picrate*, m. p. 229—231°), and 1-benzyl-3 : 4-dihydro*iso*quinoline (picrate, m. p. 182°, not 174—175° [Pictet and Kay, *loc. cit.*]). Oxalodi-β-phenylethylamide yields a *substance* (*hydrochloride*, m. p. 191—193° ; *picrate*, $C_{24}H_{21}O_8N_5$, m. p. 167—168°, canary-green needles), which is probably 3 : 4-*dihydro*iso-*quinolyl*-1-*carboxy*-β-*phenylethylamide*, $C_9NH_8 \cdot CO \cdot NH \cdot CH_2 \cdot CH_2Ph$, since it yields β-phenylethylamine and a derivative of *iso*quinoline by hydrolysis by hydrochloric acid at 120°. Even by energetic treatment, the substance cannot be converted into bis-3 : 4-dihydro*iso*quinolyl.

Homopiperonoylhomopiperonylamine yields 1-*piperonylnorhydras-tinine* (annexed formula), m. p. 136—137°, colourless plates (*picrate*, m. p. 220—223° [decomp.] ; *platini-chloride*, decomp. 175—180°), to-gether with another base, *picrate*, m. p. 228°.

Phenylacetohomopiperonylamide yields 1 - benzylnorhydrastinine

(*picrate*, m. p. 205—206° [decomp.]), whilst *benzohomopiperonylamide*, $CH_2O_2:C_6H_3\cdot CH_2\cdot CH_2\cdot NH\cdot COPh$, m. p. 122°, colourless needles, prepared by heating *homopiperonylamine benzoate*, m. p. 115°, yellowish-green needles, at 180° (compare this vol., i, 272), or from homopiperonylamine by the Schotten-Baumann method, yields 1-*phenylnorhydrastinine*, $C_{16}H_{13}O_2N$, m. p. 141°, colourless prisms (*methiodide*, m. p. 241° ; *picrate*, m. p. 188—190°).

Formohomopiperonylamide yields by condensation *norhydrastinine*,

$$CH_2O_2:C_6H_2 \underset{CH=N}{\overset{CH_2\cdot CH_2}{<}},$$ m. p. 90—91°, stout needles (*picrate*, m. p.

237—238° ; *hydrochloride*, m. p. 192° ; *platinichloride*, decomp. about 240°), the chief product, however, being *homopiperonylaminomalondihomopiperonyldiamide*,

$$CH_2O_2:C_6H_3\cdot CH_2\cdot CH_2\cdot NH\cdot CH(CO\cdot NH\cdot CH_2\cdot CH_2\cdot C_6H_3\cdot CH_2O_2)_2,$$

m. p. 124—126° (decomp.), colourless needles, which forms a *picrate*, m. p. 210—211° (decomp.), yellow plates, and *hydrochloride*, m. p. 182—183°.   C. S.

Syntheses of Hydrastinine and its *N*-Homologues. HERMAN DECKER (*Annalen*, 1913, **395**, 321—328).—Norhydrastinine (preceding abstract) and methyl sulphate react in toluene at 100° to form 2-*methylnorhydrastinine methosulphate* (*hydrastinine methosulphate*),

$$C_{10}H_9O_2NMe\cdot SO_4Me,$$

m. p. 117—119°, pale yellow, crystalline powder, from which hydrastinine is liberated by 15% sodium hydroxide at 0°.

Norhydrastinine in alcohol reacts with benzyl chloride at 50° to form the *benzylochloride*, $C_{10}H_9O_2NCl\cdot CH_2Ph$, m. p. 215°, pale yellow powder, and with ethyl iodide to form the *ethiodide*, $C_{10}H_9O_2NEtI$, m. p. 222°, yellow leaflets ; 2-*ethylnorhydrastinine picrate* has m. p. 175°.   C. S.

Synthesis of Cotarnine and Third Synthesis of Hydrastinine. HERMAN DECKER and PAUL BECKER (*Annalen*, 1913, **395**, 328—342). —*Formylhomomyristicylamine*, $CH_2O_2:C_6H_2(OMe)\cdot CH_2\cdot CH_2\cdot NH\cdot CHO$, m. p. 105—106° (corr.), colourless needles, obtained by heating homomyristicylamine formate at 160—170° for three hours, is converted, by phosphoryl chloride in boiling toluene and subsequently basifying the aqueous solution of the product, into *norcotarnine*,

$$CH_2O_2:C_6H(OMe) \underset{CH=N}{\overset{CH_2\cdot CH_2}{<}},$$
(*picrate*, m. p. 182—184°, yellow needles), the methiodide of which, m. p. 184—186° (decomp.), is identical with cotarnine hydriodide, and the methosulphate of which is converted into cotarnine picrate (Salway, T., 1911, **97**, 1208) by alcoholic picric acid.

Equal molecular quantities of homopiperonylamine and benzaldehyde react on the water-bath to form *benzylidenehomopiperonylamine*, $CH_2O_2:C_6H_3\cdot CH_2\cdot CH_2\cdot N:CHPh$, m. p. 36°, pale yellow prisms, which is converted by methyl iodide (without a solvent) at 100° into the *methiodide*. The latter is hydrolysed by boiling 95% alcohol or by steam, yielding benzaldehyde and *homopiperonylmethylamine hydriodide*,

m. p. 135—136° (corr.), colourless leaflets. *Homopiperonylmethylamine*, $C_{10}H_{13}O_3N$, b. p. 156—158°/24 mm., pale yellow oil (*carbonate*, m. p. 72—75°; *hydrochloride*, m. p. 183—185°; *picrate*, m. p. 166—167° [corr.]), is converted into formylhomopiperonylmethylamine by heating its formate at 150—160° for seven hours. By condensation with phosphoryl chloride in boiling toluene and basification of the product, the formyl derivative is converted into hydrastinine.

By processes similar to the preceding, *benzylidenehomopiperonylamine* and its *ethiodide*, homopiperonylethylamine hydriodide, m. p. 126—128°, white leaflets, and the corresponding *hydrochloride*, m. p. 183—185°, and *picrate*, m. p. 135—136°, orange-red leaflets, *formylhomopiperonylethylamine*, and 2-ethylnorhydrastinine (preceding abstract) have been prepared.

When a certain temperature or duration of heating is exceeded, by-products are obtained in the interaction of benzylidenehomopiperonylamine and an alkyl haloid. Their production is due to the formation of homopiperonyl haloid, which reacts with the benzylidene compound in the same manner as does the alkyl haloid, a derivative of dimethylamine being produced simultaneously. As an illustration of such heterospasis (compare Decker and Fellenberg, A., 1909, i, 116), equal molecular quantities of benzylidenehomopiperonylamine and methyl iodide have been heated in benzene at 140° for six hours and the product has been hydrolysed by steam, whereby *dihomopiperonylamine hydriodide*, $NH(CH_2 \cdot CH_2 \cdot C_6H_3 \cdot CH_2O_2)_2,HI$, m. p. 234—236°, pale yellow prisms, has been obtained. The corresponding *base* has m. p. 72—75° (decomp.).

Moreover, quaternary ammonium haloids are formed when moisture is present during the interaction of benzylidenehomopiperonylamine and an alkyl haloid; in the preceding example, *homopiperonyltrimethylammonium iodide*, m. p. 260—261°, is formed. C. S.

Syntheses of Tetrahydroisoquinoline Derivatives.

HERMAN DECKER and PAUL BECKER (*Annalen*, 1913, **395**, 342—362).—Homopiperonylamine or a similar derivative of β-phenylethylamine reacts readily at the ordinary temperature with an equal molecular quantity of an aldehyde to form the alkylidene derivative, which is converted into a tetrahydroisoquinoline derivative by a suitable catalyst; homopiperonylamine (or similar base) and the aldehyde, reacting directly in the presence of the catalyst, yield quite different products.

By adding slowly a benzene solution of benzylidenehomopiperonylamine to moderately warm, concentrated hydrochloric acid, the *hydrochloride*, m. p. 309—311°, of 1-*phenyldihydronorhydrastinine*,

$$CH_2O_2{:}C_6H_2\underset{\diagdown CHPh \cdot NH}{\overset{\diagup CH_2---CH_2}{\big<}},$$
m. p. 97—98°, large, hexagonal leaflets, is obtained; the *nitrate* and *picrate*, m. p. 169—170° (decomp.), dark yellow prisms, are described. The same base is produced by reducing 1-phenylnorhydrastinine (preceding abstract) by alcohol and 2·5% sodium amalgam, the solution being kept acid by the addition of glacial acetic acid.

Piperonylidenehomopiperonylamine, m. p. 117—118° (unstable *picrate*, m. p. 143—145°), and *cinnamylidenehomopiperonylamine*, m. p.

61—63°, are respectively prepared from equal molecular quantities of the components on the water-bath.

The slow addition of homopiperonylamine to 20% formaldehyde yields *homopiperonylmethylenamine*, CH_2O_2:C_6H_3·CH_2·CH_2·N:CH_2, a liquid, which is converted by hydrochloric acid on the water-bath into the *hydrochloride*, m. p. 274—276°, of *dihydronorhydrastinine*, $C_{10}H_{11}O_2N$, m. p. 81—83°. This base, the hydrochloride of which is also obtained by reducing norhydrastinine with tin and hydrochloric acid, forms a *hydrobromide*, m. p. 256—258°, *picrate*, m. p. 229—231° (decomp.), and *carbonate*, m. p. 114—115° (decomp. corr.), and reacts in benzene with methyl iodide to form the hydriodide, m. p. 239—241° (Freund and Will record 232°) of dihydrohydrastinine. Dihydronorhydrastinine and methyl sulphate react in benzene to form a crystalline substance, m. p. 135—137°, which is converted, by successive treatment with sodium hydrogen carbonate and hydrochloric acid, into dihydrohydrastinine hydrochloride, m. p. 276—278°. Dihydrohydrastinine in the form of its hydrochloride is obtained directly from homopiperonylamine hydrochloride by heating it with 40% formaldehyde at 130° for three hours. The same hydrochloride is also produced from homopiperonylmethylamine hydrochloride or dihydronorhydrastinine hydrochloride and an excess of 40% formaldehyde at 120°.

The paper closes with an explanation of Eschweiler's process of methylation by means of formaldehyde which is represented by the scheme :

$$RR'NH,HX \longrightarrow RR'N \begin{cases} CH_2 \cdot OH \\ CH_2 \cdot OH \\ X \end{cases} \longrightarrow$$

$$RR'N \begin{cases} Me \\ CHO \\ X \end{cases} \longrightarrow RR'NMeX + H \cdot CO_2H.$$
This explanation is in harmony with the fact that quaternary ammonium salts are not produced by Eschweiler's method, and, applied to phenols, will account for the frequent occurrence of the methoxyl group in plant substances.   C. S.

Synthesis of Pyrroles from Amino-ketones and Ketones or Ketonic Esters. OSCAR PILOTY and PAUL HIRSCH (*Annalen*, 1913, 395, 63—74).—The synthesis of pyrrole derivatives by Knorr's method of condensing amino-ketones and esters of β-ketonic acids in glacial acetic acid fails in many cases. The authors now find that condensation in alkaline solution is much more satisfactory, and that ketones can be used instead of ketonic esters. An aqueous solution of the amino-ketone hydrochloride is treated with an excess of an alkali hydroxide, the ketone or ketonic ester is added, and the closed vessel is kept at a gentle heat or left for several days at the ordinary temperature; thus aminoacetone yields 2 : 4-dimethylpyrrole with acetone, 2-*phenyl-4-methylpyrrole*, m. p. 152°, with acetophenone, 2 : 3 : 4-trimethylpyrrole with methyl ethyl ketone, 3 : 4-*dimethyl-2-ethylpyrrole*, an oil (*picrate*, m. p. 122·5°), with diethyl ketone, whilst methyl α aminoethyl ketone yields 2 : 3 : 5-*trimethylpyrrole*, b. p. 75·5—76·5°/16 mm. (and tetramethylpyrazine as a by-product), with

acetone, and $2:3:4:5$-*tetramethylpyrrole* (*picrate*, m. p. 125—126°), and chiefly tetramethylpyrazine, with methyl ethyl ketone.

Aminoacetone yields ethyl $2:4$-dimethylpyrrole-3-carboxylate with ethyl acetoacetate, and *ethyl hydrogen 3-methylpyrrole-4 : 5-dicarboxylate*,

$$NH \Big\langle {}^{CH=\!\!=\!\!=CMe}_{C(CO_2H)\cdot C\cdot CO_2Et},$$ m. p. 196°, with ethyl oxalacetate; by hydrolysis the ethyl hydrogen ester is converted into *3-methylpyrrole-4(or 5)-carboxylic acid*, m. p. 149°, which yields 3-methylpyrrole by heating.

Methyl α-aminoethyl ketone yields *ethyl hydrogen 2 : 3-dimethylpyrrole-4 : 5-dicarboxylate*, m. p. 201° (decomp.), and tetramethylpyrazine, with ethyl oxalacetate. By hydrolysis the ester yields $2:3$-*dimethylpyrrole-4(or 5)-carboxylic acid*, m. p. 188°, which decomposes at 190—195° in carbon dioxide to form $2:3$-*dimethylpyrrole*, b. p. 62°/11 mm. (*picrate*, $2C_6H_9N,C_6H_2(NO_2)_3\cdot OH$, m. p. 146·5°).

C. S.

A New Method of Preparing Cyclamine-aldehydes and -alcohols. II.

ADOLF KAUFMANN and LOUIS G. VALLETTE (*Ber.*, 1913, 46, 49—57. Compare A., 1912, i, 655).—In the earlier paper, the aldehydes obtained by the scission of the condensation products of nitrosodimethylaniline with 2-methylquinoline ethiodide and α-picoline methiodide were isolated only as phenylhydrazones; processes are now described for the separation of the aldehydes in a free state.

6-Methoxylepidine ethiodide, yellow or brown needles decomposing at 177—179°, gives in dilute aqueous solution a beautiful blue fluorescence; it condenses with nitrosodimethylaniline when heated in alcoholic solution, with the formation of the p-*dimethylaminoanil* of *6-methoxyquinoline-4-aldehyde ethiodide*, green columns, m. p. 214—215°, which gives blue solutions in alcohol and carmine-red in water; this substance dissolves in dilute hydrochloric acid, undergoing scission into p-aminodimethylaniline and *6-methoxyquinoline-4-aldehyde ethiodide*, the latter of which can be easily separated as the *phenylhydrazone*, red needles decomposing near 248°.

The dimethylaminoanil of quinoline-2-aldehyde ethiodide (*loc. cit.*) is hydrolysed by mineral acid, and phenylhydrazine precipitates the phenylhydrazone of quinoline-2-aldehyde ethiodide; if the addition of the phenylhydrazine be delayed for a time, the precipitate obtained is a mixture of the above with the *phenylhydrazone* of *quinoline-2-aldehyde ethochloride*, red needles, m. p. 180° (decomp.), which on reduction with zinc and dilute hydrochloric acid yields a pungent smelling, oily *base*, together with some aniline.

The hydrolysis of the dimethylaminoanil of pyridine-2-aldehyde methiodide likewise yields the methiodide and *methochloride* of the aldehyde, which can be separated as the phenylhydrazones, that of the methochloride decomposing near 235° after previous fusion in its water of crystallisation near 70°.

If the phenylhydrazone of pyridine-2-aldehyde methiodide, after previous careful removal of water of crystallisation, is heated below its m. p. (244°) under 0·1—0·2 mm. pressure (obtained by Wohl's

method with liquid air and charcoal), methyl iodide is liberated with the formation of *pyridine-2-aldehyde phenylhydrazone*, yellow needles or leaflets, m p. 180—182°; *hydrochloride*, orange-yellow needles, m. p. 188° (decomp.). The methochloride can also be used for the reaction.

In a similar manner the phenylhydrazone of quinoline-2-aldehyde ethiodide can be decomposed to produce *quinoline-2-aldehydephenylhydrazone*, yellowish-brown needles or leaflets, m. p. 203—204°; *hydrochloride*, red needles, m. p. about 237° (decomp.) (compare von Miller and Spady, A., 1886, 370).

Pyridine-2-aldehydephenylhydrazone undergoes reversible hydrolysis when treated with warm mineral acid, but the addition of dinitrobenzaldehyde causes the removal of the phenylhydrazine by forming a very sparingly soluble phenylhydrazone, and the hydrolysis then proceeds to completion ; free *pyridine-2-aldehyde* is a pungent liquid, b. p. 210°/725 mm., which gives the usual aldehyde reactions except with Fehling's solution.

Quinoline-2-aldehyde, obtained by hydrolysis of the phenylhydrazone at 120—130° under pressure, forms colourless tablets, m. p. 70—71° (compare von Miller and Spady, *loc. cit.*).   D. F. T.

4-Quinolyl Ketones. II. ADOLF KAUFMANN, MAX KUNKLER, and HEINRICH PEYER (*Ber.*, 1913, **46**, 57—64. Compare A., 1912, i, 1017).—From a comparison of the cinchona alkaloids the conclusion is drawn that a substance of the structure 6-alkyloxy-4-(β-dialkylamino-a-hydroxyalkyl)-quinoline should possess properties similar to those of quinine.

4-Quinolyl methyl ketone has b. p. 99°/0·08 mm., and 4-quinolyl phenyl ketone, m. p. 59°, b. p. 142°/0·12 mm.

6-Ethoxyquinoline (Kaufmann and Peyer, A., 1912, i, 650) readily unites with methyl sulphate with the formation of a yellow solid, the fluorescent solution of which when treated with potassium cyanide yields *4-cyano-6-ethoxy-1-methyl-1 : 4-dihydroquinoline* ; the ethereal extract of this substance is oxidised by alcoholic iodine to red needles of *4-cyano-6-ethoxyquinoline methiodide*, m. p. 183—184° (decomp.), which when heated near its m. p. in a vacuum liberates methyl iodide, leaving free *4-cyano-6-ethoxyquinoline* as yellow needles m. p. 118°, which give fluorescent solutions. When treated in benzene solution with an ethereal solution of magnesium methyl iodide the cyano-compound is converted into 6-*ethoxy-4-quinolyl methyl ketone*, golden-yellow leaflets or needles, m. p. 80—81°, whilst with magnesium ethyl iodide in an analogous manner, 6-*ethoxyquinolyl ethyl ketone*, golden-yellow crystals, m. p. 92°, is produced ; both ketones with dilute acids give yellow solutions with a greenish fluorescence.

6-Methoxy-4-quinolyl methyl ketone, dissolved in acetic acid of 50% concentration, is reduced by zinc dust to 6-*methoxy-4-quinolyl methyl carbinol*, needles, m. p. 120—121°, which gives a blue fluorescence in dilute sulphuric acid, and an emerald-green coloration with chlorine water and ammonia.

4-Quinolyl methyl ketone in alcoholic solution containing sodium

ethoxide is converted by amyl nitrite into 4-*quinolyl oximinomethyl ketone*, colourless needles, m. p. 237—242° (decomp.), which gives a yellow *substance* with phenylhydrazine, and is reduced by an acid solution of stannous chloride to β-*amino-α-hydroxy-4-quinolylethane* (annexed formula); *hydrochloride*, a greyish-white powder, m. p. 208—210° (decomp.); *picrate*, leaflets, m. p. 202°.

$CH(OH)\cdot CH_2\cdot NH_2$
D. F. T.

A Methylnaphthaisoquinoline. Amé Pictet and B. Manevitch (*Arch. Sci. phys. nat.*, 1913, [iv], **35**, 40—47. Compare Pictet and Gams, A., 1909, i, 671).—The preparation of 1-methyl-α-naphthaisoquinoline (annexed formula) is described.

A mixture of α- and β-naphthyl methyl ketones was obtained by the addition of aluminium chloride to a solution of naphthalene and acetyl chloride in carbon disulphide. The two isomerides were separated by treatment of their alcoholic solution with a saturated solution of picric acid, whereby the α-naphthyl methyl ketone picrate was precipitated, from which, by decomposition with sodium carbonate, α-naphthyl methyl ketone, b. p. 292—293°, was isolated in 25—30% yield. β-Naphthyl methyl ketone, b. p. 171—172°/12 mm., m. p. 51°, was obtained from the mother liquor, the yield being 12—15%. Attempts to prepare the α-ketone by the action of acetyl chloride on an ethereal solution of magnesium α-naphthyl bromide were less successful.

α-*Naphthyl oximinomethyl ketone*, m. p. 183°, was formed by the gradual addition of amyl nitrite to an alcoholic solution of α-naphthyl methyl ketone in the presence of sodium ethoxide, and was transformed into α-*naphthyl aminomethyl ketone hydrochloride*, m. p. 245—250° (decomp.) by reduction with stannous chloride. The free *base* was unstable.
α-*Naphthyl acetylaminomethyl ketone*, $C_{10}H_7\cdot CO\cdot CH_2\cdot NHAc$, m. p. 103°, prepared by the action of acetic anhydride and potassium hydroxide on a concentrated aqueous solution of the above hydrochloride, was reduced by means of sodium amalgam to the corresponding *carbinol*, needles, m. p. 145—146°, which, when treated with phosphoric oxide in boiling xylene solution, was transformed into 1-*methyl-α-naphthaisoquinoline*, m. p. 95—96°.

H. W.

Amino-Imino-Desmotropy. Kurt H. Meyer and Hans Schlosser (*Ber.*, 1913, **46**, 29—32).—It has already been shown (Meyer, A., 1911, i, 193) that 9-hydroxyanthracene exhibits tautomerism between its enolic and ketonic isomeric structures (anthranol and anthrone), and it is now discovered that similar tautomerism can exist in the anthracene group with 9-aminoanthracene derivatives.

The oxidation of 9-aminoanthracene by amyl nitrite (Kaufler and Suchannek, A., 1907, i, 225) or by bromine in alcoholic solution gives

rise to a substance, m. p. 204—205°, which from its lack of colour and of fluorescence must be dianthronedi-imine,

$$\mathrm{NH{:}C}\!\!\begin{array}{c}\mathrm{C_6H_4}\\\mathrm{C_6H_4}\end{array}\!\!\!\!>\!\!\mathrm{CH\cdot CH}\!\!<\!\!\begin{array}{c}\mathrm{C_6H_4}\\\mathrm{C_6H_4}\end{array}\!\!\!\!\mathrm{C{:}NH} \; ;$$

it is a diacid base, and the course of the oxidation is evidently analogous to that of anthranol (Meyer, *loc. cit.*). When the substance is boiled for an hour with a methyl-alcoholic solution of potassium hydroxide, it is converted into the isomeric diaminodianthryl,

$$\mathrm{NH_2\cdot C}\!\!<\!\!\begin{array}{c}\mathrm{C_6H_4}\\\mathrm{C_6H_4}\end{array}\!\!\!\!>\!\!\mathrm{C\cdot C}\!\!<\!\!\begin{array}{c}\mathrm{C_6H_4}\\\mathrm{C_6H_4}\end{array}\!\!\!\!>\!\!\mathrm{C\cdot NH_2},$$
golden-yellow leaflets, m. p. 334° (compare Gimbel, A., 1887, 1049), which dissolves in benzene to a solution with a green fluorescence. The same isomeric change can be induced less readily by boiling with acetic acid or by fusion, but the reverse change from the amino- to imino-compound could not be accomplished. **D. F. T.**

Phenylbenzylidenehydrazine. GEORG LOCKEMANN and FRANZ LUCIUS (*Ber.*, 1913, **46**, 150—152).—Thiele and Pickard (A., 1898, i, 474) obtained by the action of acetic anhydride and zinc chloride or sulphuric acid on phenylbenzylidenehydrazine an isomeric β-modification of the hydrazine, m. p. 136°. On repetition the only product now obtained is α-acetyl-α-phenyl-β-benzylidenehydrazine, m. p. 122°. **E. F. A.**

Constitution of "Anilipyrine." EZIO COMANDUCCI (*Boll. chim. farm.*, 1912, **51**, 741—743).—Two "anilipyrines" have been described, of which one was supposed to result from the condensation of equimolecular quantities of antipyrine and acetanilide, and the other from two molecules of antipyrine with one molecule of acetanilide. By the method of thermal analysis, the author now shows that these substances are neither compounds nor even mixed crystals, but consist simply of crystalline mixtures. When fused mixtures of the antipyrine and acetanilide are cooled, an eutectic is observed corresponding with 45% of antipyrine and 45°. The behaviour of the "anilipyrines" with solvents supports the above results. **R. V. S.**

Constitution of "Anilipyrine." LINO METELLO ZAMPOLLI (*Boll. chim. farm.*, 1912, **51**, 780—782. Compare preceding abstract).—Polemical. The author appears to be in agreement with Comanducci's conclusions as now stated. From his preliminary experiments, however, the eutectic temperature is at least 48·5°. **R. V. S.**

Reaction Products from 1-Phenyl-3-methyl-5-pyrazolone and Phthalic Anhydride. GUSTAV SCHULTZ and GEORG ROHDE (*J. pr. Chem.*, 1913, [ii], **87**, 119—142.)—When crystallised from ethyl acetate or acetone, the product, formed by fusing 1-phenyl-3-methyl-5-pyrazolone with phthalic anhydride in equimolecular proportions at 120°, yields an orange-yellow, crystalline *substance*, which becomes red and melts at 202—204°, and on crystallisation from methyl alcohol and acetic acid, or on treatment with aqueous alkalis, loses phthalic

acid and is converted into the red substance first observed by Knorr (A., 1887, 601).

The latter compound is best prepared by boiling the product of the fusion with water until it is completely soluble in chloroform. It crystallises in clusters of dark red prisms or thin, lancet-shaped leaflets, m. p. 208—210° or above, according to the rapidity of heating, and when heated with phthalic acid in acetone or ethyl acetate solution is transformed into the above-mentioned yellow substance.

The constitution of the red substance is represented by one of the following formulæ :

$$C \cdot C_6H_4 \cdot CO_2H \qquad\qquad C \cdot C_6H_4 \cdot CO_2H$$

$$N{<}{\overset{CMe \cdot C}{NPh \cdot CO}}{\overset{CH \cdot CMe}{CO-NPh}}{>}N \qquad N{<}{\overset{CMe \cdot C}{NPh \cdot CO}}{\overset{C \text{---} CMe}{C(OH) \cdot NPh}}{>}N.$$

It separates from methyl alcohol and chloroform in red prisms, containing the solvent, and dissolves in aqueous alkalis and alkaline carbonates, forming orange-red salts ; the red mono- and di-*silver* salts are mentioned. With methyl-alcoholic hydrogen chloride, it forms a *methyl* ester, $C_{29}H_{24}O_4N_2$, which crystallises in orange-yellow prisms or plates having a bluish glance, m. p. 178—179°, and yields a red *silver* salt, $C_{29}H_{23}O_4N_4Ag$. When heated in nitrobenzene solution or in other solvents of high b. p., the red substance decomposes into 1-phenyl-3-methyl-5-pyrazolone and 1-*phenyl-3-methyl-4-pyrazol-5-onyl-idenephthalide*, $\overset{N=CMe}{\underset{NPh \cdot CO}{|}}{>}C{:}C{<}\overset{C_6H_4}{\underset{O}{|}}{>}CO$. This crystallises in slender, red needles, which sinter at 208°, and have m. p. 212—219°, according to the rapidity of heating. It combines with 1-phenyl-3-methyl-5-pyrazolone in boiling cumene solution to form the original red compound, and is resolved by aqueous alkalis into the ketonic *acid*, $\overset{N=CMe}{\underset{NPh \cdot CO}{|}}{>}CH \cdot CO \cdot C_6H_4 \cdot CO_2H$, which forms lustrous, yellow leaflets of variable m. p. (145—160°), and is reconverted by the action of acetic anhydride into the phthalide.

When warmed with acetic anhydride and a little sulphuric acid, the original red substance is transformed into an *anhydride* (annexed formula), crystallising in slender, colourless needles, m. p. 261°; the reverse transformation may be effected by boiling the anhydride with alcoholic alkali hydroxides.

$$C_6H_4{<}{\overset{CO}{C}}{>}O$$

$$N{<}{\overset{CMe \cdot C}{NPh \cdot C}}{\underset{O}{-}}{\overset{C \cdot CMe}{C \cdot NPh}}{>}N$$

F. B.
The Constitution of the Pyrazolinecarboxylic Acids. AUGUST DARAPSKY (*Ber.*, 1913, **46**, 218—225).—Polemical ; a reply to Bülow (this vol., i, 101).

D. F. T.

A New Example of the Reversed Pinacolin Rearrangement. HEINRICH BILTZ and KARL SEYDEL (*Ber.*, 1913, **46**, 138—142).—4:5-Di-phenyldihydroglyoxalone, $\overset{CPh \cdot NH}{\underset{CPh \cdot NH}{|}}{>}CO$, is oxidised by nitric acid to

4:5-diphenyldihydroglyoxalone glycol, $\begin{array}{c}\text{HO·CPh·NH}\\\text{HO·CPh·NH}\end{array}{>}\text{CO}$, which in presence of alkaline hydroxides undergoes a normal pinacolin rearrangement into 5:5-diphenylhydantoin, $\begin{array}{c}\text{CPh}_2\text{·NH}\\\text{CO——NH}\end{array}{>}\text{CO}$ (compare Biltz, A., 1909, i. 525).

When this hydantoin is energetically reduced with hydrogen iodide and phosphorus, 4:5-diphenyldihydroglyoxalone is obtained together with decomposition products, the phenyl group returning to its original place.

The decomposition products include diphenylacetic acid and diphenylmethane, indicating that in the hydantoin the two phenyl residues are attached to the same carbon atom.

On reducing 5:5-diphenylhydantoin by distillation with zinc dust, diphenylmethane and benzonitrile are formed, the latter being due to the rearrangement into diphenylglyoxalone which gives rise to benzonitrile when distilled with zinc dust.

Di-p-bromo-4:5-diphenylhydantoin is very resistant to hydrogen iodide and phosphorus. Only bis-p-bromophenylmethane could be isolated from the reaction products; the presence of di-p-bromodiphenylacetic acid and of di-p-bromodiphenyldihydroglyoxalone was made probable.   E. F. A.

Phenazine. FRIEDRICH KEHRMANN and EM. HAVAS (*Ber.*, 1913, **46**, 341—352).—The authors have obtained good yields of phenazine by the action of *o*-aminodiphenylamine on *o*-nitrodiphenylamine in the presence of anhydrous sodium acetate, and have examined several of its derivatives.

o-Nitrodiphenylamine was obtained in 85—90% yield by heating *o*-chloronitrobenzene, aniline, and anhydrous sodium acetate during twelve to fifteen hours at 215°. Reduction of its alcoholic solution by stannous chloride and hydrochloric acid gave *o*-aminodiphenylamine. For the preparation of phenazine, *o*-nitrodiphenylamine, *o*-aminodiphenylamine, and anhydrous sodium acetate were heated at about 250°, when a violent reaction occurred. The phenazine was isolated by distillation of the crude product, or, better, by treatment with superheated steam; yield, 60—70%. In the absence of sodium acetate, only traces of phenazine could be obtained.

When dissolved in nitrobenzene and treated with methyl sulphate, phenazine yielded *methylphenazonium methosulphate* as greenish-yellow prisms. The corresponding *platinichloride*, $C_{26}H_{22}N_4Cl_6Pt$, and *dichromate*, $C_{26}H_{22}N_4O_7Cr_2$, were analysed, but the *chloride*, *bromide*, and *nitrate* were found to be so readily soluble in water that they could not be precipitated from a solution of the sulphate. When concentrated aqueous potassium iodide was added to an aqueous solution of methylphenazonium methosulphate, an orange-coloured solution was obtained, which, after a short time, deposited greenish-black needles. The latter dissolved readily in hot alcohol with formation of a greenish-yellow solution, which, when rapidly cooled, yielded bluish leaflets, which could be ground to a dirty-green powder.

Analyses of the crystals yielded figures agreeing with those required by the normal iodide, $C_{13}H_{11}N_2I$. The authors, however, are led to the conclusion that this substance is only contained in the yellow solution, and that the crystals probably consist of a quinhydrone salt composed of 1 mol. of methylphenazonium tri-iodide and 2 mols. of methyldihydrophenazine.

In the presence of air, sodium hydroxide transformed a solution of methylphenazonium methosulphate into phenazine mixed with small quantities of a red *substance*, probably having the annexed formula. Similarly, aqueous ammonia yielded mainly phenazine when brought into reaction with methylphenazonium salts, but, in the absence of water, salts of 3 aminomethylphenazonium were readily obtained. Of these, the following were isolated, namely, the *chloride*, *bromide*, and *nitrate*, green needles which yielded magenta-red solutions, and the *platinichloride*.

1 : 3-*Dinitrophenazine* was obtained by cautiously heating phenazine with sulphuric acid and rather more than the calculated amount of nitric acid to 130°. It crystallised in yellow needles, which had no definite m. p., but decomposed above 200°. Reduction of this substance by hydrogen sulphide in ammoniacal alcoholic solution led to the formation of dinitrodihydrophenazine (annexed formula), the constitution of which follows from its identity with the compound prepared by Kehrmann and Messinger (A., 1894, i, 55), and by Leemann and Grandmougin (A., 1908, i, 478), from o-phenylenediamine and picryl chloride. Attempts to reduce 1 : 3-dinitrophenazine or its dihydro-derivative to diaminophenazine were unsuccessful.

The authors have re-investigated the acetylation of dihydrophenazine (compare Hinsberg and Garfunkel, A., 1897, i, 123; Tichwinski and Wolochowitsch, A., 1905, i, 383; Hinsberg, A., 1905, i, 840). They find that pure acetic anhydride and pure dihydrophenazine yield only a monoacetyl derivative, whilst the diacetyl derivative is immediately formed if a trace of zinc chloride is added. They consider that dihydrophenazine and its diacetyl derivative possess a symmetrical structure, whilst the yellow monoacetyl derivative and dihydrophenazine sulphate are probably derived from the annexed unsymmetrical form.

A solution of dihydrophenazine diacetate in glacial acetic acid was mixed with concentrated nitric acid and warmed on the water-bath, whereby a mixture of 2-*nitrophenazine*, m. p. 214°, and *nitrodiacetyldihydrophenazine*, m. p. 166°, was obtained. The latter substance yielded 3-aminophenazine when warmed with concentrated sulphuric acid.

2-Aminophenazine (compare Fischer and Hepp, A., 1889, 500) was obtained by reduction of an alcoholic solution of nitrodiacetyldihydrophenazine by stannous chloride and hydrochloric acid, oxidation of the tin salt so obtained by ferric chloride solution, and liberation of the base by means of ammonia. H. W.
New Methods of Preparation of Asymmetric $\alpha\beta$-Naphthazine. Fritz Reitzenstein and Franz Andre (*J. pr. Chem.*, 1913, [ii], **87**, 97—118).—*as*-$\alpha\beta$-Naphthazine (Fischer and Junk, A., 1893, i, 283) has been prepared (1) from β-naphthylamine by the action of sulphur monochloride or sulphuryl chloride in pyridine solution, and also by distillation over magnesium and barium peroxides; (ii) from α-naphthylamine by heating with calcium oxide, and (iii) by sublimation of aceto-β-naphthylamide over a mixture of barium peroxide and calcium oxide. It forms greenish-yellow crystals, m. p. 278—281°, according to the method of preparation, and yields a dinitro-derivative, m. p. 330—332°, which is reduced by aqueous sodium sulphide to diaminonaphthazine (compare D.R.-P. 166363). When warmed with alcohol and hydrochloric acid, it forms an unstable red *hydrochloride*.

In pyridine solution, sulphuryl chloride reacts with α-naphthylamine, yielding a red *substance*, m. p. 169°, and with aceto-β-naphthylamide to form aceto-1-chloro-β-naphthylamide.

When distilled over a mixture of barium peroxide and calcium oxide, benzidine yields a substance, m. p. 122°, probably identical with the azine, $NH_2 \cdot C_6H_4 \cdot C_6H_3 < \!\!\!\begin{smallmatrix} N \\ N \end{smallmatrix}\!\!\!> C_6H_3 \cdot C_6H_4 \cdot NH_2$, isolated by Kalb (*Diss.*, München, 1905) from the product obtained by oxidising benzidine. The action of sulphuryl chloride on benzidine in pyridine solution gives rise to a *substance*, m. p. 126°, which is considered to be a chloroderivative of benzidine or of the above-mentioned azine.   F. B.

Synthesis of Two Isomeric Oxytetrazoles from Azoimide and Fulminic Acid. F. Carlo Palazzo and G. Marogna (*Gazzetta*, 1913, **43**, i, 69—80).—The interaction of azoimide and fulminic acid yields, not only the 1-hydroxytetrazole previously described (compare Palazzo, A., 1910, i, 342), but also an isomeride of this substance. Its formation is favoured by a low temperature. The *sodium* salt of iso*oxytetrazole*, $CHON_4Na,3H_2O$, forms large crystals, which have been described by Rosati (this vol., i, 207). It yields other salts by double decomposition, and gives also a *benzoyl* derivative, which crystallises in needles, m. p. 94°. The sodium salt is stable towards water and alkalis, but with sulphuric acid or with fuming hydrochloric acid suffers a decomposition analogous to that of its isomeride. The iso*oxytetrazole*, $CHON_3 \colon NH$, is obtained by treating the sodium salt with cold, dilute sulphuric acid; it has m. p. 155° (softening a few degrees previously). The decomposition of this substance with sulphuric acid is similar to that of the isomeride, but hydrochloric acid acts somewhat differently. The acid and its salts explode on percussion and also when heated.

The 1-hydroxytetrazole previously described forms when treated with diazomethane an ether containing a methoxyl group; it has m. p. 93—94°. The *iso*oxytetrazole forms an *N*-ether.

The authors consider that the *iso*oxytetrazole probably has the following structure: $\begin{smallmatrix} CH \colon NO \\ N =\!\!= N \end{smallmatrix}\!\!> NH$. They regard the production of these two isomerides from fulminic acid as a further proof of the tautomeric nature of that substance.   R. V. S.

Halogen Substitution Products of Azo-dyes. S. WEBER (*Monatsh.*, 1913, **34**, 243—254).—The influence of halogen substitution on the shade and usefulness of some dyes has been systematically studied.

Group A.— o-, m- and p-Chloro-, bromo-, and iodo-anilines, diazotised and coupled with β-naphthol-8-sulphonic acid in sodium carbonate solution, give yellow to red dyes, the p-compounds being darker and the m-compounds lighter than the o-members, whilst the shades deepen from chlorine to iodine.

Group B.—The same bases give redder dyes with α-naphthol-2 : 8-disulphonic acid, but the same generalisations may be made.

Group C.—Aniline, m- and p-bromoaniline do not couple so readily with 1-amino-β-naphthol-6-sulphonic acid, and the dyes are dark red tinged with blue.

Group D.—2 : 4-Dibromoaniline is less easily diazotised and coupled than the mono-derivatives, but gives deeper colours with the above sulphonates.

The dyes are faster than the unsubstituted analogues, and their colouring power is much enhanced. The ortho- and para-compounds are more valuable than the meta-, and the bromo- and iodo-derivatives are much more effective that the chloro-dyes.　　　　　J. C. W.

Congo-Red. I. Experimental Part. F. I. BOGOJAVLENSKI. II. Theoretical Part. VLADIMIR G. SCHAPOSCHNIKOV (*J. Russ. Phys. Chem. Soc.*, 1912, **44**, 1813—1844).—The action of either strong or weak acids (even carbonic acid) on Congo-red results in the replacement of the sodium by hydrogen. With strong acids the action proceeds rapidly and yields a dark blue precipitate, which when washed gives a blue colloidal solution; the latter cannot be freed from admixed impurities by washing or dialysis. This solution of Congo-blue exhibits electrical conductivity, which is, however, probably conditioned by the impurities present. The action of weak acids gives the same product, but in a crystalline condition. Very small crystals of Congo-blue are capable of forming suspensions which closely resemble the colloidal solutions; both the colloidal particles and the crystals carry negative charges, both are coagulated without change of structure by acids or acid salts, and both the colloidal solution and the filtered crystalloidal suspension show Brownian movement under the ultramicroscope, the crystals passing through the filter.

The theoretical considerations of Part II lead to the following conclusions. The change in colour of substantive bisazo-colouring matters is conditioned by change in their intramolecular structure. The red forms of amino- and hydroxybisazo-colouring matters of the Congo-red type correspond with the azoid configuration of the molecules, whilst the blue forms correspond with the quinonoid structure. The instability of these forms and their ready interconversion are regarded as due to the agency of so-called "suspensive" linkings and of mobile hydrogen.　　　.　　T. H. P.

Aniline-Black and Allied Compounds. III. ARTHUR G. GREEN and SALOMON WOLFF (*Ber.*, 1913, 46, 33—49).—See P., 1912, 28, 250.

The Density and Solution Volume of Some Proteins. (Miss) HARRIETTE CHICK and CHARLES J. MARTIN (*Biochem. J.*, 1913, 7, 92—96).—A comparison was instituted in the case of four proteins, caseinogen, egg-albumin, serum-albumin, and serum-globulin, between the density directly determined with dry specimens and that calculated from the specific gravity of concentrated solutions. The latter is found to be 5 to 8% in excess of the former, showing the extent of shrinkage in volume taking place when these proteins enter into colloidal solution.   W. D. H.

The Hydrolysis of Organic Phosphorus Compounds by Dilute Acid and Dilute Alkali. R. H. ADERS PLIMMER (*Biochem. J.*, 1913, 7, 72—80).—Ethyl dihydrogen phosphate, glycerophosphoric acid, and phytic acid are hydrolysed by acid, but are stable to alkali. Hexose-phosphoric acid and phospho-protein behave so differently to alkali from the other three compounds mentioned, that they are probably not esters. In phospho-proteins, the phosphoric acid is probably united to one of the amino-acids. Hexose-phosphoric acid reduces Fehling's solution, which points to the presence of a functioning aldehyde or ketone group. Some suggestions as to atomic grouping are made to explain the differences in reaction referred to.
                                    W. D. H.

Protein Compounds. WALTER H. EDDY (*Biochem. Bull.*, 1912, 2, 111—122).—A description is given of protein salts formed by combining organic bases (strychnine, morphine, etc.) with acid reacting proteins (mucoids, nucleoproteins) and by combining the latter with basic reacting proteins, such as histone. It is pointed out that so-called histone, however, is itself probably a protein salt.
                                    W. D. H.

Bilirubin and Hæmin. HANS FISCHER (*Zeitsch. physiol. Chem.*, 1913, 83, 170).—Polemical. A reply to Küster (this vol., i, 210).
                                    E. F. A.

The Action of Pepsin-Hydrochloric Acid on Proteins Partly Digested with Trypsin. VALDEMAR HENRIQUES and J. K. GJALDBÆK (*Zeitsch. physiol. Chem.*, 1913, 83, 83—92).—Egg-white and caseinogen partly digested with trypsin behave differently when submitted to the subsequent action of pepsin-hydrochloric acid, the former being more readily changed, and the yield of formaldehyde-titratable nitrogen being greater.   W. D. H.

Activity of Koji Sucrase [Invertase] in the Presence of Different Acids. GABRIEL BERTRAND, M. ROSENBLATT, and (Mme.) M. ROSENBLATT (*Compt. rend.*, 1913, 156, 261—263. Compare A., 1912, i, 148, 327, 401).—A study of the diastatic activity of the

sucrase, known as "taka-diastase," extracted from the Japanese Koji, in the presence of various acids. This sucrase, unlike those obtained from yeast and *Aspergillus niger*, shows a maximum activity in solutions the concentration of which with respect to hydrogen ions practically corresponds with neutrality to helianthin, and is independent of the nature of the acid. W. G.

Enzymic Decomposition of Glucosides and Galactosides. HENRY BIERRY (*Compt. rend.*, 1913, 156, 265—267. Compare A., 1909, ii, 747).—A résumé of the work already published on the enzymic hydrolysis of α- and β-glucosides and galactosides by various ferments. The author finds that the digestive juice of the *Helix* attacks both α- and β-galactosides. The lactase obtained from the intestine of a dog appears to be much more specific in its action, only attacking derivatives of galactose, and of these only the β-derivatives, from which it seems to make a restricted choice in that it hydrolyses lactose itself, but neither α- or β-methyl galactoside. W. G.

The Rate of Destruction of Ptyalin by the Direct Electric Current. W. E. BURGE (*Amer. J. Physiol.*, 1913, 31, 328—333).— The passage of the direct electric current destroys ptyalin, but this is not due to electrolytic products. The rate of destruction is uniform, and was 2·5% per coulomb for the solutions used. W. D. H.

Resistance of Emulsin to the Action of Heat in Presence of Strong Alcohol. EMILE BOURQUELOT and MARC BRIDEL (*J. Pharm. Chim.*, 1913, [vii], 7, 65—67).—In a previous paper (this vol., i, 212), it was shown that the temperature at which emulsin is rendered inactive falls as the concentration of alcohol increases to 50%, but that with stronger alcohols the temperature of inhibition rises with the concentration of the alcohol. It was suggested that this phenomenon is due to the fact that in the stronger alcohols the ferment is precipitated, and in this condition is more resistant to heat. Experiments are now described which prove this contention ; thus, it was found that emulsin was scarcely weakened in action when mixed with dry alcohol, and the latter heated slowly to the boiling point and maintained at this temperature during two minutes. In sterilising plants containing enzymes, therefore, it is best to use alcohol of such a strength as to produce a liquid containing about 60% of alcohol when the plants are immersed in it, allowance being made for the water in the plants. T. A. H.

Enzyme Action. III. Action of Manganous Sulphate on Castor Bean Lipase. K. GEORGE FALK and MARSTON L. HAMLIN (*J. Amer. Chem. Soc.*, 1913, 35, 210—219. Compare Falk and Nelson, A., 1912, i, 523, 593).—Experiments are described which show that when a preparation of castor bean lipase which has been rendered inactive by heating with water is treated with manganous sulphate it becomes slightly active again. In order to explain this behaviour, it is suggested, that although the active enzyme is hydrolysed by the action of hot water, the inactive zymogen present in the pre-

paration is not wholly destroyed, and that the manganous sulphate effects the conversion of the inactive zymogen into active enzyme by a process of oxidation.   E. G.

Enzymic Decomposition of Hydrogen Peroxide. IV. PERCY WAENTIG and OTTO STECHE (*Zeitsch. physiol. Chem.*, 1913, **83**, 315—337. Compare A., 1911, i, 759 ; 1912, i, 228 ; ii, 839).—The action of several proteoclastic and other enzymes on active preparations of catalase has been studied. Trypsin alone destroys the catalase, indicating the protein nature of this substance. The experiments are not in favour of the possible destruction of a protective colloid by the trypsin, thereby destroying the catalase as well. The resistance of catalase to hydrolysis by pepsin suggests that it has a polypeptide structure, but it is possible that the experimental conditions were adverse to the action of pepsin, since the solutions could not be made more than faintly acid.

The gastric juice of the cray fish was especially active in destroying catalase—this confirms its tryptic nature. The action on catalase affords a method of detecting and possibly of measuring tryptic enzymes. Differences are noted in the resistance of blood catalase to the tryptic ferments of vertebrates and of the crayfish, and also in the behaviour of catalases of different origin to the same trypsin.

                                                    E. F. A.

Neutralisation of Solutions of Diaminodihydroxyarseno-benzene Hydrochloride. J. CHARLES BONGRAND (*J. Pharm. Chim.*, 1913, [vii], **7**, 49—55).—Theoretically this drug requires 4 mols. of sodium hydroxide to neutralise it by conversion into the disodium derivative. The author shows by means of cryoscopic and electrical conductivity determinations that in dilute solutions, as used in practice, hydrolytic dissociation occurs, and that more than the theoretical amount of sodium hydroxide is then required to maintain the drug in solution, as the disodium derivative.   T. A. H.

Phenylstibines. PAUL CARRÉ (*Bull. Soc. chim.*, 1913, [iv], **13**, 102—104).—Magnesium phenyl bromide reacts with antimony trichloride to form triphenylstibine together with the chlorides of phenyl stibine and diphenylstibine, the first being almost the sole product when a small proportion of the magnesium compound is used, whilst with 1 or 2 mols. larger quantities of the two latter substances are simultaneously produced. Phenylstibine and diphenylstibine chlorides are decomposed by heat into antimony trichloride and triphenylstibine (compare Michaelis and Günther, A., 1911, i, 1056).   T. A. H.

Mercury Dibenzyl. PAUL WOLFF (*Ber.*, 1913, **46**, 64—66).—The description of mercury dibenzyl given by Campisi, in 1865, is erroneous, and endeavours to prepare this substance by the action of sodium amalgam on benzyl chloride have been futile, producing only dibenzyl. The substance has been successfully obtained by the application of magnesium benzyl chloride [see Pope, following abstract].

Mercury dibenzyl is formed, and crystallises in long, colourless needles, m p. 111° [Pope and Gibson give 104°], which decompose above the m. p. into mercury and dibenzyl. When heated in alcoholic solution with mercuric chloride, *mercury benzyl chloride*, leaflets, m. p. 104°, is obtained ; *mercury benzyl bromide* and *mercury benzyl iodide*, prepared in an analogous manner, also form colourless leaflets, m. p. 119° and 117° respectively; *mercury benzyl cyanide*, needles, m. p. 124°, for its formation requires mercury dibenzyl and mercuric cyanide to be heated together in alcoholic solution at 130°. *Mercury benzyl acetate* is produced by the interaction of mercury dibenzyl and mercuric acetate in alcoholic solution, and also of mercury benzyl chloride and silver acetate in alcoholic solution.

Mercury dibenzyl when heated with acetic acid for two or three hours at 170° undergoes decomposition into mercury, toluene, benzyl acetate, and dibenzyl.   D. F. T.

Mercury Dibenzyl. WILLIAM J. POPE (*Ber.*, 1913, **46**, 352).— Mercury dibenzyl has been obtained previously to Wolff (preceding abstract) by Pope and Gibson, using the same method (T., 1912, **101**, 735).   T. S. P.

Physiological Chemistry.

The Effects of Muscular Exercise in Man. FRANK COOK and MARCUS S. PEMBREY (*J. Physiol*, 1913, **45**, 429—446).—The average composition of alveolar air in healthy men is oxygen, 14·9%, and carbon dioxide, 5·57%. The mean respiratory quotient was 0·9. Directly after muscular exercise the alveolar air contained 14·33% oxygen and 6·52% carbon dioxide; the mean respiratory quotient was 1. During muscular dyspnœa the respiratory quotient affords no definite indication of the metabolism, for the vigorous ventilation of the lungs washes out the carbon dioxide. The administration of oxygen is of value only in pathological conditions. The pulse rate in healthy men at rest varies from 45 to 90 per minute. In a trained man the pulse rate is slower during rest, has a wider range in response to muscular work, and rapidly recovers after exercise. "Second wind" is an adjustment of the respiratory and circulatory systems to the demands of the muscles for an adequate supply of blood; carbon dioxide is the chief factor in effecting the accommodation.   W. D. H.

Influence of Calcium and Potassium in the Respiratory Rhythm in Frogs. DONALD R. HOOKER (*Proc. Amer. physiol. Soc.*, 1912 ; *Amer. J. Physiol.*, **31**, xvii—xviii).—In the absence of calcium from a perfusion fluid, the respiratory centre is excited; in the absence of potassium it is depressed. In the presence of potassium decrease in the calcium causes depression, and an increase excita-

tion. In the presence of calcium, a decrease in the potassium causes excitation, and an increase causes depression.   W. D. H.

The Oxygen Capacity of Blood in Relation to the Concentration of Hæmoglobin. J. H. BURN (*J. Physiol.*, 1913, **45**, 482—488).—No alteration in the oxygen capacity of the blood was discovered when the blood is diluted. Manchot states that it is increased.   W. D. H.

Determination of the Constant of the Differential Blood-Gas Apparatus and the Specific Oxygen Capacity of Blood. JOSEPH BARCROFT and J. H. BURN (*J. Physiol.*, 1913, **45**, 493—497). —This apparatus can be best calibrated by the liberation of a known quantity of oxygen from a standard solution of hydrogen peroxide by potassium permanganate. The constant obtained is then higher than by previous methods. Applying this constant, the specific oxygen capacity of hæmoglobin becomes 401·8, the theoretical figure being 400·8 c.c. of oxygen per gram of iron.
                                                                W. D. H.

The Effect of Exercise on the Dissociation Curve of Blood. JOSEPH BARCROFT, R. A. PETERS, FF. ROBERTS, and J. H. RYFFEL *Proc. physiol. Soc.*, 1913; *J. Physiol.*, **45**, xlv).—The following new terms are introduced. The blood is said to be *mesectic* when the dissociation curve is normal; *pleonectic* when at any given pressure of oxygen the hæmoglobin takes up more of that gas than normal; and *meionectic* when it takes up less. The immediate effect of severe exercise is to shift the curve in the direction of greater acidity, even though the carbon dioxide tension is reduced. After rapid climbing, the curve becomes meionectic; after slow climbing, it remains mesectic.   W. D. H.

The Effect of Altitude on the Dissociation Curve of Blood. JOSEPH BARCROFT, MARIO CAMIS, G. C. MATHISON, FF. ROBERTS, and J. H. RYFFEL (*Proc. physiol. Soc.*, 1913; *J. Physiol.*, **45**, xlvi).— Although altitudes up to 15,000 feet lower the carbon dioxide alveolar pressure, the blood of the resting subject remains mesectic, for other acids in the blood compensate for the carbon dioxide. Meionexy is brought on by exercise more readily than at the sea level.   W. D. H.

The Effect of Carbohydrate-free Diet on the Dissociation Curve of Blood. JOSEPH BARCROFT, G. GRAHAM, and HAROLD L. HIGGINS (*Proc. physiol. Soc.*, 1913; *J. Physiol.*, **45**).—In three out of five cases the curve remained mesectic, although the carbon dioxide tension fell. In two cases it became pleonectic, and the subjects felt knocked up and faint.   W. D. H.

The Effect of Moist Heat on the Dissociation Curve of Blood. JOSEPH BARCROFT, MARIO CAMIS, G. C. MATHISON, FF. ROBERTS, and J. H. RYFFEL (*Proc. physiol. Soc.*, 1913; *J. Physiol.*, **45**, xlvii—xlviii).—With the wet bulb at 24·5° the carbonic acid

tension fell (as it often does in factories under similar conditions), and the blood became pleonectic. In all these conditions the subject feels well if his blood is mesectic; but variations in either direction produce symptoms of ill-health. W. D. H.

Sugar Loosely Combined in the Blood. RAPHAEL LÉPINE and RAYMOND BOULUD (*Compt. rend.*, 1913, **156**, 110—112. Compare A., 1904, ii, 56; 1907, ii, 562).—The authors have estimated not only the free sugar in the blood of dogs, but also the sugar liberated, after destroying the glycolytic ferment by heating the blood mixed with water at 58° for fifteen minutes, by the addition of emulsin and invertase and keeping the mixture at 39° for forty-five minutes. There is but little or no difference in the amounts of sugar liberated from arterial and venous blood, and but little and in some cases no sugar is liberated from the blood of normal dogs bled for the first time. The amount becomes considerable (up to 50% increase of total sugar) after the physiological equilibrium of the dog has been subjected to marked disturbance by such means as (*a*) severe hæmorrhage, (*b*) intravenous injection of amylase or pancreatin or extracts of liver or pancreas, (*c*) subcutaneous injection of phloridzin. In some cases, also, the intravenous injection of 2 grams of dextrose per kilo. of body-weight was followed by a rise in the amount of sugar liberated by the above method. W. G.

The Behaviour of Blood-Sugar in Normal and Pathological Cases. IV. The Blood-Sugar in Febrile and Dyspnœic Conditions of Man. FR. ROLLY and FR. OPPERMANN (*Biochem. Zeitsch.*, 1913, **48**, 259—267. Compare this vol., ii, 159).—In febrile conditions in man, there is an increase of blood-sugar which at times is quite considerable. There is, however, no parallelism between the increased amount and the rise in the height of the temperature. The hyperglycæmia is caused partly by the hyperthermia and bacterial toxins. In cases of dyspnœa, without high temperatures, where the carbon dioxide content of the blood is increased, hyperglycæmia also occurs. There are, therefore, in certain cases, two distinct causes for increased sugar in the blood, namely, febrile conditions and dyspnœa. Toxic substances, of varied origin, such as tolylenediamine, can also give rise to hyperglycæmia. S. B. S.

The Behaviour of Blood Sugar in Normal and Pathological Cases. V. The Blood-Sugar in Nephritis, Arteriosclerosis, and Diseases of the Nerves. FR. ROLLY and FR. OPPERMANN (*Biochem. Zeitsch.*, 1913, **48**, 268—277).—Inflammation of the kidneys by itself does not give rise to hyperglycæmia. When such occurs in conjunction with inflammation of the kidneys, it is caused by other factors, which are concomitant pathological conditions, such as arteriosclerosis, dyspnœa, uræmic coma, or bacterial and other toxins. There is no parallelism between the hyperglycæmia and the degree of hypertension. In cases of diseases of the nerves the behaviour of the blood-sugar showed great variations, which depend largely on the seat and character of the affection. S. B. S.

Fibrinsæmia. J. O. WAKELIN BARRATT (*J. Path. Bact.*, 1913, 17, 301—322).—If thrombin or thrombokinase is injected into the blood-stream of rabbits, separation of fibrin occurs in the circulating blood; the rate of intravascular clotting varies, and is specially readily produced in the right side of the heart; the circulation is by this means mechanically interfered with.   W. D. H.

The Sodium and Carbonate Ions in the Serum, and the Question of the "Non-diffusible" Alkali. PETER RONA and PAUL GYORGY (*Biochem. Zeitsch*, 1913, 48, 278—290).—The method of compensation dialysis was employed in these experiments, the serum being placed in a dialysing membrane, and surrounded by water containing various amounts of salts, the mixtures being kept at the same hydrogen ion concentration as the serum by means of phosphate mixtures. By analysis, after a definite time the amount of salt in equilibrium with that in the serum was ascertained. It was found that the amount of sodium in equilibrium with that of the serum was 0·3260%, whereas the amount in serum determined directly was 0·3057%. There was therefore practically no non-diffusible sodium. The amount of potassium and sodium in equilibrium was found by dialysis to be 0·9214%, whereas the amounts in serum were 0·8532%. In taking into account these two numbers, the volume occupied by the serum proteins must also be considered. The amount of diffusible carbon dioxide was 0·1270%, and that estimated directly in the serum was 0·1270% in one experiment, and similar numbers were obtained from other series. The greater part of the carbon dioxide is therefore diffusible, although a small part is apparently combined as a carbamido-derivative of the proteins.   S. B. S.

Rate of Regeneration of Anti-substances [Specially Hæmolysin) and Other Constituents of the Blood after Hæmorrhage. R. A. O'BRIEN (*J. Path. Bact*, 1913, 17, 425).—The experiments were made on horses. After bleeding, the constituents of the blood are replaced at differing rates; the volume returns to the normal within forty-eight hours; the proteins commence to be reproduced within twenty-four hours, and the red corpuscles and hæmoglobin within two days. The alterations in leucocytes are irregular, and cannot be correlated with any other factor. The production of anti-substances is as rapid as that of the blood-volume, and suggests that the tissues have a long, persistent habit of forming them in the absence of specific antigens.   W. D. H.

Can Lipoids Act as Antigens? JAMES RITCHIE and J. MILLER (*J. Path. Bact.*, 1913, 17, 429—431).—No evidence was found that lipoids can act in this way.   W. D. H.

Hydrolysis of Glycogen by Diastatic Enzymes. Comparison of Glycogen from Various Sources. ROLAND VICTOR NORRIS (*Biochem. J.*, 1913, 7, 26—42).—On hydrolysis with extract of pig's pancreas, the glycogen is rapidly converted into dextrins and

maltose; the further cleavage of the dextrins is slow and incomplete. The optimum temperature for glycogen hydrolysis is 37°, for starch 40°. When excess of glycogen is present the action is a linear one. The concentration of glycogen has little influence on the initial rate of hydrolysis unless very low concentrations are employed. The action is hindered slightly by the products of hydrolysis; it is favoured by traces of acid. Samples of glycogen from different sources are hydrolysed at different rates at the optimum hydrogen ion concentration; thus, taking dog glycogen as 100, the relative rates of hydrolysis are: rabbit glycogen, 94; oyster, 88; and yeast, 84. The degree of opalescence and the coloration with iodine also vary. The difference may be due to differences in constitution, or to variations in colloidal state. If the glycogens are distinct, the enzymes which affect them should be specific; this is to be tested. W. D. H.

The Secretion of Pancreatic Juice.
Iwawo Matsuo (*J. Physiol.*, 1913, **45**, 447—458).—In the preparation of secretin from the intestinal mucous membrane, boiling with 0·6% sodium chloride is as effective as 0·4% hydrochloric acid; organic acids give a smaller yield. Injection of salt solution into the duodenum does not, however, cause a flow of pancreatic juice as the injection of acid does. Secretin was not obtained from any other organ. If two dogs are in vascular connexion, injection of acid into the duodenum of one evokes a pancreatic flow from the other. After the introduction of hydrochloric acid into the duodenum, the duodenal contents contain secretin. Secretin, however, is not absorbed from the intestinal contents, nor does it produce its effects when given under the skin. The view that secretin and " vaso-dilatin " are identical is negatived. W. D. H.

The Rôle of the Pituitary in Carbohydrate Metabolism.
Lewis H. Weed, Harvey Cushing, and Conrad Jacobson (*Proc. Amer. Physiol. Soc.*, 1912; *Amer. J. Physiol*, **31**, xiii—xiv).—The posterior lobe of the pituitary plays an important part in carbohydrate metabolism, and its action is controlled by fibres in the cervical sympathetic nerve. Stimulation of this nerve, or of the " sugar centre " in the bulb, or of the pituitary body itself, liberates a hormone which causes glycogenolysis and glycosuria, independently of any possible nervous impulse reaching the muscles or abdominal viscera. W. D. H.

Carbohydrate Metabolism in Ducks.
G. B. Fleming (*Proc. physiol. Soc.*, 1913; *J. Physiol.*, **45**, xliii—xliv).—Partial removal of the pancreas in ducks raises the amount of sugar in the blood, but does not produce glycosuria. Complete extirpation of the organ has a more pronounced effect on the blood, and sometimes leads to glycosuria. Subcutaneous injection of adrenaline after partial extirpation lowers the percentage of sugar in the blood, and in half the experiments produced glycosuria. The respiratory quotient after fasting averaged 0·72; after feeding on maize, 0·93; after

adrenaline, 0·88. This suggests that the effect of adrenaline is to mobilise carbohydrates; its effect passes off rapidly.   W. D. H.

Nitrogen Retention on Feeding with Urea. EMIL ABDER-HALDEN and ARNO ED. LAMPÉ (*Zeitsch. physiol. Chem.*, 1913, 83, 338—346).—Polemical. A reply to Grafe and Turban (this vol., i, 216).   E. F. A.

Protein Metabolism from the Point of View of Blood and Tissue Analyses. VI. Uric Acid, Urea, and Total Non-protein Nitrogen in Blood. OTTO FOLIN and W. DENIS (*J. Biol. Chem.*, 1913, 14, 29—43).—By the authors' new methods it is possible to measure various degrees of nitrogen retention and urea accumulation due to kidney insufficiency with considerable accuracy. Numerous analyses of the uric acid, urea, and total non-protein nitrogen in the blood are presented both in health and disease. The figures show that there is no relationship between the amount of uric acid and that of urea and non-protein nitrogen. Uric acid may accumulate in the blood, even although urea and other nitrogenous waste products are eliminated quite as well as by normal kidneys; the damage to the kidney in gout may thus affect only its power to eliminate uric acid. Apparently very slight kidney damage may affect its power to excrete uric acid.   W. D. H.

The Metabolism of Organic Phosphorus Compounds; Their Hydrolysis by the Action of Enzymes. R. H. ADERS PLIMMER (*Biochem. J.*, 1913, 7, 43—71)—The action of enzymes is summarised in the following table:

	Pancreas.	Liver.	Intes-tine.	Castor oil seeds.	Yeast (zymin).	Bran.
Glycero-phosphoric acid	0	0	+	+		
Hexose-phosphoric ,, ...	0		+	+	*	+
Ethyl dihydrogen phosphate .	0		+			+
Diethyl hydrogen ,,			0	0		
Phytic acid	0	0	0		0	+
Nucleic acid (thymus)	0		+		+ ?	
,, (wheat)			+ /			
,, (meat)	0					
Hydroxymethylphosphinic acid	0		0	0	+ /	0
Phosphoprotein..................	+		+		0	0

The most active tissue is the intestinal mucosa. Phytic acid is attacked readily by bran extract only. Phosphoprotein is the only compound hydrolysed by the pancreas. The other compounds in the list are esters; it is evident that the enzyme which attacks them is not lipase. The question whether the phosphatases are single or specific is discussed, and it is suggested that there are mono- and di-phosphatases. Phytase is specific, and if phytin is decomposed in the intestine, this is due to phytase swallowed with the food. It then enters the body as inositol and phosphoric acid. The work of Fingerling and Gregersen is confirmed, that the animal body can and does synthesise its organic phosphorus compounds from inorganic phosphates.   W. D. H.

The **Rate of Protein Katabolism.** E. PROVAN CATHCART and HENRY HAMILTON GREEN (*Biochem. J.*, 1913, **7**, 1—17).—The rise in the output of nitrogen and sulphur after a protein meal is due to katabolism of the actual material ingested, and not to the displacement of "effete" protoplasm from the tissues. This conclusion is based on the ratio of the sulphur and nitrogen in the urine; after ingesting egg albumin the S : N ratio is 1 : 8, which is nearly the same as that in egg-albumin. The ratio in starvation when all the urinary constituents must arise from the tissues is 1 : 15. The sulphur is more rapidly excreted than the nitrogen; this confirms the view of previous investigators that the sulphur-containing moiety of the protein is the more rapidly katabolised. When protein is superimposed on a low protein diet, a retention of part of the nitrogen takes place. The retained material is apparently stored in the tissues (? muscles) as a pabulum of uniform composition. There was no effect on the output of creatinine.

W. D. H.

The **Metabolism of Lactating Women.** EDWARD MELLANBY (*Proc. Roy. Soc.*, 1913, *B*, **86**, 88—109).—The post-partum excretion of creatine does not depend on the involution of the uterus. After Cæsarian section, involving amputation of the uterus, it may become more marked than in cases in which the uterus is left intact. Rabbits do not excrete creatine at this period; the explanation of this is not obvious. Eating the placenta will not explain the difference, for cows after eating the placenta, excrete large quantities of creatine. The creatine excretion has some relation to the activity of the mammary gland. The rise in the creatine : creatinine ratio in the first few days after delivery corresponds with the increased activity of the milk glands and the development of milk from colostrum. The increase of weight in healthy breast-fed children is roughly proportional to the amount of creatine in the mother's urine. If the activity of the breasts is delayed after childbirth, so also is the excretion of creatine, and later both develop at the same time. Milk suppression from disease is accompanied by a suppression also of creatine excretion. Feeding with caseinogen does not affect the excretion of creatine in parturient women. The post-partum excretion of creatine is dissimilar from that accompanying acidosis and lack of carbohydrates. Lactose and dextrose added to the diet do not affect it. W. D. H.

Nutrition of the Embryonic Chick. I. **The Absorption of Egg-white.** HUBERT W. BYWATERS (*Proc. physiol. Soc.*, 1913; *J. physiol.*, **45**, xl—xli).—During incubation, the proteins of the white are not absorbed as quickly as the water, and the ratio of coagulable to uncoagulable protein remains constant; the free sugar is rapidly absorbed; there is no cleavage of carbohydrate from the protein. W. D. H.

The **Importance of Phosphorus in the Nutrition of Growing Dogs.** ERNST DUBLACH (*Arch. expt. Path. Pharm.*, 1913, **71**, 210—250).—Young dogs fed on a diet poor in phosphorus stop

growing, waste, and die. This, however, is not wholly attributable
to lack of phosphorus. The absence of other unknown constituents
of a diet, possibly of lipoid nature, seems to be a factor, as in
Stepp's experiments. Inorganic phosphates appear to be as advan-
tageous for nutrition as phosphatides.   W. D. H.

Nutritive Value of the Maize Proteins. THOMAS B. OSBORNE
and LAFAYETTE B. MENDEL (*Proc. Amer. physiol. Soc.*, 1912; *Amer. J.
Physiol.*, 31, xvi—xvii).—Zein alone produces speedy decline in the
growth of rats; it can be made adequate for maintenance by adding
tryptophan, or by the addition of another protein. Gliadin suffices
for maintenance, but not for growth. Glutelin is adequate for
both.   W. D. H.

The Influence of Diets upon Growth. F. GOWLAND HOPKINS
and ALLEN NEVILLE (*Biochem. J*, 1913, 7, 97—99).—A criticism of
the work of Osborne and Mendel on the nutrition of young
animals on purified proteins (A, 1912, ii, 271). If these workers
are correct, the accessory factors in diet (so-called vitamines) are
not indispensable. The present experiments do not support this
view. On the Osborne-Mendel diet the animals did not grow; but
an addition to it daily of 2 c.c. of milk produced growth. W. D. H.

Fasting PAUL E. HOWE (*Biochem. Bull.*, 1912, 2, 90—100).—
A general discussion of the subject based on the author's work,
with special reference to fasting as a therapeutic agent. Long fasts
are devoid of benefit, and may be dangerous. Short fasts may be
beneficial in certain cases.   W. D. H.

A New Method of Drying Tissues and Glands. JACOB
ROSENBLOOM (*J. Biol. Chem.*, 1913, 14, 27—28). - Instead of using
anhydrous salts, the employment of calcium carbide is recom
mended [compare Masson, T., 1910, 97, 857].   W. D. H.

A New Type of Artificial Cell. E. NEWTON HARVEY (*Biochem.
Bull.*, 1912, 2, 50—52).—The manner of making cells of about the
size of those in the body is described; they contain an aqueous
solution of lecithin enclosed in a fine protein membrane, and are
suitable for permeability and other biochemical studies. W. D. H.

Pigment of the Corpus luteum. HEINRICH H. ESCHER (*Zeitsch.
physiol. Chem.*, 1913, 83, 198—211).—Willstatter and Escher (A.,
1912, i, 125) have shown that lutein, the yellow pigment of egg
yolk, belongs to the xanthophyll group of pigments soluble in
alcohol. It is now proved that the yellow pigment of the *Corpus
luteum* belongs to the carrotene group, $C_{40}H_{56}$, soluble in light
petroleum. The process of purification adopted in obtaining 0·45
gram of pigment from 146 kilos. (about 10,000 ovaries) is described.
The carrotene is indistinguishable from that obtained from carrots
or from green leaves. The yellow pigment of fat is considered to
belong to the same class of pigments.   E. F. A.

The Lipoids of the White and Grey Matter of the Human Brain at Different Ages. J. LORRAIN SMITH and W. MAIR (*J. Path. Bact.*, 1913, **17**, 418—420).—Five brains were analysed by the methods previously described. The results are given in tables. In the adult the percentage of total lipoids is twice as great in the white as in the grey matter, but the cerebroside is higher, and the phosphatide much lower, than in the grey matter. At birth, there is a low percentage of phosphatides, and more of other lipoids, and the composition is nearly the same throughout the brain. By the age of two, the condition in the adult is nearly, but not quite, reached.   W. D. H.

Chemical Changes in Nerve During the Passage of a Nerve Impulse. SHIRO TASHIRO (*Proc. Amer. Physiol. Soc*, 1912; *Amer. J. Physiol.*, **31**, xxii—xxiii).—The author states that he has constructed an apparatus by which he is able to detect and estimate carbon dioxide in amounts as small as 0.0000001 gram. Resting nerve gives off this gas, and the amount is increased when the nerve is stimulated.   W. D. H.

The Utilisation of Sugars by the Normal Heart. HUGH MACLEAN and (Miss) IDA SMEDLEY (*J. Physiol.*, 1913, **45**, 462—469). —Locke's method for the isolated heart was employed. The utilisation of sugar by the heart is not confined to dextrose; mannose is also used, and so is lævulose, especially in the dog's heart. Maltose, lactose, and sucrose are not utilised, and galactose very slightly. In the cat, sugar does not disappear from the circulating fluids until about three hours after perfusion commences; it is assumed that the reserves in the heart are utilised first. It was found difficult to secure asepsis during the experiments.   W. D. H.

The Behaviour of the Diabetic Heart towards Sugar. HUGH MACLEAN and (Miss) IDA SMEDLEY (*J. Physiol.*, 1913, **45**, 470—472). -The normal power to consume sugar is absent or nearly so in the heart of the depancreatised dogs; the power can be sometimes restored by the addition of pancreatic extract. These experiments confirm those of Knowlton and Starling.   W. D. H.

The Storage and Release of Glycogen. KUNTOMI ISHIMORI (*Biochem. Zeitsch.*, 1913, **48**, 332—346).—The methods of experiment were both chemical (estimation of glycogen) and histological (with use of Best's carmine method). Rabbits were employed. It was found that the course of disappearance of glycogen produced by starvation was different from that produced by *piqûre*. In the former case, it disappears from the periphery of the lobe, towards the centre, and glycogen as such could not be detected outside the liver cells. In the latter case, all the liver cells are affected alike, and glycogen could be detected in the lymph spaces and circulation. Intravenous infusion of dextrose and lævulose caused an increase in the glycogen content of the liver. This was not the case with lactose, galactose, and sucrose.   S. B. S.

The Character of the Fat Formation in Organs after Phosphorus Poisoning. HANS LEO (*Biochem. Zeitsch.*, 1913, **48**, 297—301).—The author recapitulates the evidence in favour of the new formation of fat in the liver of animals poisoned with phosphorus, which probably exists in this organ in addition to the transported fat.   S. B. S.

Fat Formation under the Influence of Phosphorus. HANS LEO and W. TRASCHENNIKOV (*Biochem. Zeitsch.*, 1913, **48**, 302—312). —The majority of the experiments were carried out with the livers of rabbits, part of which were incubated under precautions for strict asepsis in Ringer's fluid alone as a control, and part under the same conditions with the addition of phosphorus. After incubation, the amount of ether-soluble substances, or higher fatty acids, were estimated. In eight experiments the addition of phosphorus caused an increase in fatty substances. In three experiments the results were of a negative character.   S. B. S.

Fat Formation in the Surviving Liver. HANS LEO and C. BACHEM (*Biochem. Zeitsch*, 1913, **48**, 313—327).—The effect produced on the fat content of livers by perfusing both foodstuffs and toxic substances through the surviving organs was investigated. Livers both of cold-blooded and warm-blooded animals were used. and the Langendorff apparatus was employed. In five experiments with foodstuffs (sugar or nutrose in Ringer's fluid), the results indicated fat formation, whereas in four experiments the results were negative. All the experiments with livers of warm-blooded animals yielded a positive result. The addition of alcohol and potassium arsenite showed no fat formation In four experiments with diphtheria toxin, one gave a negative, one a doubtful result, and two others indicated fat formation in the liver. Out of fourteen experiments with phosphorus water, ten gave negative, and four positive results. The general result indicates that there is no new fat formation in the liver as the result of the action of phosphorus, although two of the experiments with livers of warm-blooded animals indicated an increase in fats. It is suggested that in the case of cold-blooded animals, the rate of fat formation is too slow for it to be possible to obtain an increase in the amount of fat under the conditions of experiment employed.   S. B. S.

The Delayed Heat-Production of Muscles Stimulated in Oxygen. ARCHIBALD V. HILL (*Proc. physiol. Soc*, 1912; *J. Physiol*, **45**, xxxv—xxxvii).—By improved methods the author's previous conclusion is confirmed that heat-liberation occurs largely (probably 40%) after muscular contraction; oxygen is mainly of use in repair. The action of oxygen is rapid.   W. D. H.

The Physico-chemical Basis of Striated Muscle Contraction. II. Surface Tension. WILLIAM N. BERG (*Biochem. Bull.*, 1912, **2**, 101—110. Compare this vol., i, 132).—Bernstein's calculations

of the surface energy changes in contracting muscles are criticised. The energy expended is far greater than any changes in surface tension can furnish. The use of mathematics in biology is regretted, if the treatment, as it so generally does, lacks definiteness; formulæ are often stated with no information as to their use or application to the problem under discussion. W. D. H.

Osmotic and Colloidal Imbibition by Muscle. REINHARD BEUTNER (*Biochem. Zeitsch.*, 1913, **48**, 217—224).—The experiments were carried out with the gastrocnemius muscle of frogs, and the changes after various treatments are measured by estimating the gain or loss of weight of the muscles. It was found that the addition of proteins to salt solutions in which the muscles are immersed has no appreciable effect on the water exchange between the tissues and the surrounding fluid. If the stimulability of muscle is destroyed by treatment with acid, its ordinary osmotic functions can still be detected, even for a long period after the loss of stimulability. If, on the other hand, the stimulability is destroyed by heat coagulation, the osmotic properties are lost.
S. B. S.

The Chemical Pathology of Muscle. The Influence of Disuse Atrophy in the Partition of Nitrogen and Phosphorus in the Muscle. GEORGE GRUND (*Arch. expt. Path. Pharm.*, 1913, **71**, 129—141).—Full analytical details of paralysed in comparison with healthy muscle are given. The most important result appears to be an increase of phosphorus in protein union in the paralysed muscles.
W. D. H.

The Creatine Content of Normal Muscle and its Relation to Urinary Creatinine. VICTOR C. MYERS and MORRIS S. FINE (*J. Biol. Chem.*, 1913, **14**, 9—26).—The creatine content in muscle is constant in a given animal, but differs in different animals; the percentages are 0·52 for the rabbit, 0·45 for the cat, 0·37 for the dog, and 0·39 for man. The creatinine elimination bears a distinct relation to the muscular creatine content. W. D. H.

Occurrence of Alizarin in the Shell of the Crab. FRIEDRICH KORNFELD (*Chem. Zeit.*, 1913, **37**, 71).—A reply to Grandmougin (this vol., i, 132) describing further experiments which support the view expressed previously (*Chem. Zeit.*, 1912, **36**, 59) that crab-shells contain alizarin. T. A. H.

Normal Presence of Bromine in Human Organs. A. LABAT (*Compt. rend.*, 1913. **156**, 255—258. Compare Pribram, 1907, ii, 111).—The various organs of human beings, who had not taken bromine medicinally for several years, were pulped, dried, and incinerated with calcined magnesia, and the ash examined for bromine by the method of Denigès and Chelle (this vol., ii, 72). Bromine could not be detected in the kidney, spleen, liver, heart, or blood serum or coagulum of the four subjects examined, but in

all cases was found in the brain, thyroid gland, and urine. The amount of bromine present in the thyroid gland is considerably less than the iodine.   W. G.

The Presence and Distribution of Manganese in Animal Organs. GABRIEL BERTRAND and FLORENTIN MEDIGRECEANU (*Ann. Inst. Pasteur*, 1913, **27**, 1—11).—Manganese has been found in all the animal products examined with the exception of the white of egg. The variations in amount are only small in a given organ of a given species. There is, as a rule, very little difference in the content of manganese in organs of animals of different species belonging to the same class (birds, fishes, mammals). Amongst functional organs the highest amount of manganese has been found in the uterus of birds (0·786—2·201 mg. per 100 grams). Next in order are the liver, then the kidneys. The organs of birds are richer than those of mammals. Smallest amounts are found in muscular tissue, nervous tissue, and (least of all) the lungs, which only contain 0·006 to 0·023 mg. per 100 grams. The grey nervous matter contains more than the white, and heart muscle more than the muscles of the limbs. The mucous membranes contain more than the underlying muscular tissue. Feathers and nails contain relatively large quantities of manganese (0·111 to 3·214 mg. per 100 grams), whereas the teeth contain little. Milk contains very little manganese, and in the egg the whole of the metal is in the yolk. The general results indicate that manganese plays some physiological rôle as a catalyst.   S. B. S.

The Origin of Oxalic Acid in the Animal and Human Organism. LESLAW WEGRZYNOWSKI (*Zeitsch. physiol. Chem.*, 1913, **83**, 112—142).—Proteins have no influence on the formation of oxalic acid in the body, neither have carbohydrates and fats (also glycerol). The ordinary articles of diet have no influence, direct or indirect, on oxalic acid formation. The organism evidently has a very limited capacity to form this acid at all.   W. D. H.

Histones and Nucleohistones. Their Detection in the Fluids of the Organism. GEORGES PATEIN (*J. Pharm. Chim.*, 1913, [vii], **7**, 55—60).—A description is first given of the characters of histones and nucleohistones, and by the application of Gonbau's method it is shown that these substances do not occur in the blood serum of man or the horse, or in ascitic fluid containing chyle. The conclusion is drawn therefore that histones and nucleohistones, which have only been found in such organs as the thymus and the spleen, are fixed there, and cannot be carried away by the body fluids.

Acetoglobulin tested in the course of these experiments was found to contain only traces of phosphorus, and sometimes none. T. A. H.

Relation of Pulse Pressure to Renal Secretion. ROBERT A. GESELL (*Proc. Amer. physiol. Soc.*, 1912; *Amer. J. Physiol*, **31**, xxviii—xxix).—In dogs alterations of the arterial pressure, espe-

cially if suddenly produced, cause diminution in the secretion of urine, and if albuminuria is present, this is increased. W. D. H.

Excretion of Nitrogen after Ligaturing the Renal Arteries. J. D. PILCHER (*Proc. Amer. physiol. Soc.*, 1912 ; *Amer. J. Physiol.*, 31, xii—xiii).—Tying one branch of each renal artery has no effect; but if three-fourths of the arterial supply is cut off, anorexia and loss of weight occur, and the nitrogen output is greater than the intake. The urine secreted contains neither protein nor casts. W. D. H.

Beri-Beri. The Action of Certain Purine and Pyrimidine Derivatives. CASIMIR FUNK (*J. Physiol.*, 1913, 45, 489—492) — Certain purine and pyrimidine derivatives have marked beneficial effect on pigeons suffering from polyneuritis; no relation, however, between the action and chemical structure can be discovered. Experiments with allantoin suggest that pigeons are not able to convert uric acid into allantoin. W. D. H.

Colloidal Nitrogen in the Urine of a Dog with a Breast Tumour. MAX KAHN and JACOB ROSENBLOOM (*Biochem. Bull.*, 1912, 2, 87—89).—Töpfer states that the urine of cancer patients is rich in "extractive substance," which includes "colloidal nitrogen." The colloidal nitrogen was more abundant in a dog with a tumour in the breast than in normal dogs. The nature of the tumour was doubtful. W. D. H.

The Comparative Mineralisation of Cancareous and Relatively Healthy Portions of the Liver. ALBERT ROBIN (*Compt. rend.*, 1913, 156, 334—336).—Cancareous portions of liver are richer in total inorganic matter than healthy parts, and whilst some of the inorganic constituents, namely phosphorus, sodium, potassium, magnesium, and silicon, are in excess, others, namely, calcium and iron, are deficient. A similar deficiency in calcium and iron is found in tuberculous lungs, potassium again being in excess. Whilst in the cancareous liver relatively more sodium than potassium is fixed, the reverse is true in the case of a tuberculous lung. From the experimental results, it seems probable that silicon, phosphorus, sodium, potassium, and magnesium are agents of neoplastic cell construction, not specifically for cancer, whilst iron and calcium are rather agents of organic defence. W. G.

Hæmatogenous Jaundice. GEORGE H. WHIPPLE (*Proc. Amer. physiol. Soc.*, 1912 ; *Amer. J. Physiol.*, 31, xi—xii).—If hæmoglobin is given intravenously to a normal dog, it appears in the urine, and one or two hours later bile pigment occurs there also. The same occurs after an Eck fistula, and also when the hepatic artery is tied in addition. This is taken to prove that bile pigments can be formed in the blood, probably by the agency of the endothelial cells. W. D. H.

The Swelling of Connective Tissues. EDWIN HAUBLRRISSER and FRITZ SCHONFELD (*Arch. expt. Path. Pharm*, 1913, **71**, 102—128). —Martin Fischer's theory of œdema renders necessary an investigation of the part played by different ions (for example, in Ringer's solution) in causing swelling. A large number of observations on this line are recorded, and the principal conclusion is stated to be that sodium ions do not act differently from the others. The experiments were in the main performed on the ligamentum nuchæ.   W. D. H.

Antagonism between Salts and Anæsthetics. III. Parallel Decrease in the Stimulating, Permeability-increasing, and Toxic Actions of Salt Solutions in the Presence of Anæsthetics. RALPH S LILLIE (*Amer. J. Physiol*, 1913, **31**, 255—287. Compare A., 1912, ii, 280, 468).—Pure isotonic sodium chloride solutions produce in *Arenicola* larvæ stimulation of the muscles, arrest of ciliary action, and a general toxic action. These results are lessened or prevented by anæsthetics; the stimulating action and permeability increase undergo a parallel diminution. The essential effect of anæsthetics is an alteration in the plasma membranes of the cells affected. The degree of resistance of these membranes is intimately dependent on the state of their lipoid constituents.
                                                      W. D. H.

Behaviour of Mercury in the Human and Animal Organism on the Usual Therapeutic Methods of Application. New Method for the Estimation of Mercury in Urine and in the Tissues. HANS BUCHTALA (*Zeitsch. physiol. Chem.*, 1913, **83**, 249—303).—Contains a critical summary of the methods of estimating mercury in urine with a full bibliography. A method is described of destroying the urine by evaporating with potassium chlorate and hydrochloric acid and so converting the mercury into chloride. The solution is filtered and electrolysed in a special apparatus between a cathode of gold foil and a gas carbon anode. The mercury is deposited on the gold, which is rinsed, dried and weighed, and heated to volatilise the mercury, the weight of which is determined by difference.

The skin is equally able to take up volatile and non-volatile mercury ointments; the ointment base has an accelerating influence on the resorption. The separation of mercury in the urine has been studied after internal administration, and also after intramuscular and intravenal injection of mercury salts In the latter case the separation is materially faster. The addition of potassium iodide to the mercury salt is shown to diminish the excretion of the mercury.   E. F. A.

The Influence of Alcohol on Reflex Action in the Frog. IDA H. HYDE, RUTH SPRAY, and IRENE HOWAT (*Amer. J. Physiol*, 1913, **31**, 309—317).—The reflexes investigated were from certain skin areas. If the dose of alcohol used is sufficient to produce any effect at all, it is always a depressed or slowed response, never the opposite.   W. D. H.

Glyconeogenesis. II. The Formation of Dextrose from Valeric and Heptoic Acids. A. I. RINGER and L. JONAS (*J. Biol. Chem.*, 1913, **14**, 43—52).—In phloridzinised dog-, the administration of formic acid leads to no increase in the output of dextrose; butyric and hexoic acids increase the excretion of acetoacetic and β-hydroxybutyric acids, but not that of sugar. Valeric and heptoic acids give rise to dextrose, probably because propionic acid is an intermediate substance in their katabolism, after undergoing β-oxidation. Fatty acids with an uneven number of carbon atoms can therefore give rise to dextrose. W. D. H.

The Fate of Indole-ethylamine [3-β-Aminoethylindole] in the Organism. ARTHUR J. EWINS and PATRICK P. LAIDLAW (*Biochem. J.*, 1913, **7**, 18—25).—If 3-β-aminoethylindole (Ewins, T., 1911, **99**, 270) is perfused through the surviving liver of rabbits and cats, it is converted into indoleacetic acid. If it is given by the mouth to dogs, 30% of it is excreted as *indole-3-acetylglycine*,

$$\underset{NH\cdot CH}{\overset{C_6H_4}{\diagdown}}{>}C\cdot CH_2\cdot CO\cdot NH\cdot CH_2\cdot CO_2H \quad (picrate, \text{ m.p. } 145°)$$

(for which the authors suggest the name *indoleaceturic acid*), which is formed from indoleacetic acid by combination with glycine. Neither 3-β-aminoethylindole nor indoleacetic acid affects the output of kynurenic acid. W. D. H.

Influence of Intraperitonal Injection of Adrenaline on the Partition of Urinary Nitrogen in a Dog. JACOB ROSENBLOOM and WILLIAM WEINBERGER (*Biochem. Bull.*, 1912, **2**, 123—127) — The nitrogen partition was not affected. W. D. H.

Action of Drugs on the Lungs. DENNIS E. JACKSON (*Proc. Amer. physiol. Soc.*, 1912; *Amer. J. Physiol.*, **31**, xxvi—xxvii).—Pilocarpine causes bronchial constriction, which is relieved by adrenaline. The nerve endings are sensitive to the latter drug after atropine. Agaricine slightly depresses the constrictor nerve-endings. In small doses the pilocarpine effect is followed by dilatation, but the second effect does not occur if the suprarenals are tied off. Tyramine also causes dilatation, but this is a secondary adrenaline effect also. Choline hydrochloride acts like adrenaline, so also do trimethylamine hydrochloride and 3:4-dihydroxy-phenylethylmethylamine in less degree. W. D. H.

The Pharmacological Susceptibility of the Peripheral Vascular Tonus of the Frog. HANS HANDOVSKY and ERNST P. PICK (*Arch. expt. Path. Pharm.*, 1913, **71**, 89—101).—The Läwen Trendelenburg preparation of the frog was used. Vaso-constrictors fall under three types: (1) adrenaline, which affects post-ganglionic nerve fibres; (2) nicotine, which affects pre-ganglionic and ganglionic structures; and (3) barium, which affects the muscular fibres. The dilators, tyramine, histamine, and Witte's peptone, all

act in the same way. They dilate the vessels after adrenaline is used; tyramine hinders nicotine action. Choline acts as a dilator.
W. D. H.

Nicotine and Calcium Salts. W. BURRIDGE (*Proc. physiol. Soc.*, 1912; *J. Physiol.* **45**, xxxvii—xxxix).—Isotonic solutions of sodium oxalate, sulphate, fluoride, pyrophosphate, and citrate produce a slow tonic contraction of the frog's sartorius muscle. This is attributed to the removal of calcium. Nicotine produces, in addition, twitchings, which are largely abolished by curare. W. D. H.

The Effect of Strychnine on Frogs without Heart and Lymph Hearts. SAMUEL J. MELTZER (*Proc. Amer. physiol. Soc.*, 1912; *Amer. J. Physiol.*, **31**, xix—xx).—Abel considers that the effect of drugs in a frog without a heart is brought about by the continued activity of the lymph hearts. This is not so for strychnine. Strychnine convulsions set in after thirty to fifty minutes when the lymph hearts are all destroyed. W. D. H.

Muscle Physiology. Action of Veratrine on Striated Muscles in Warm-blooded Animals. G. QUAGLIARIELLO (*Zeitsch. Biol.*, 1913, **59**, 441—468).—Veratrine causes two contractions, the second of which lasts longer. It also causes fibrillary twitchings in small doses. Variations in the curves obtained with varying doses are illustrated by reproductions of the tracings. W. D. H.

The Action on Man of Vapours of Technical and Hygienic Importance. XXX. Nitric Acid. KARL B. LEHMANN and LUDWIG DIEM (*Arch. Hygiene*, 1913, **77**, 311—322).—The toxic symptoms on animals of air contaminated by nitric acid are not particularly characteristic, and are similar to those produced by other irritant substances, such as hydrogen chloride, sulphur dioxide, etc. Three cats died in the respiration chamber in 35 to 120 minutes in the presence of 0·5 to 0·73 mg. of the acid to 1 litre of air. Two animals recovered after doses of 0·43 to 0·5 mg., and one survived until the next day with a dose of 0·88 mg. after remaining in the presence of the air-acid mixture for 200 minutes. The post-mortem examination showed no marked inflammation of the mucous membrane of the eyes, nose, or mouth, or œdema of the glottis. The bronchial passages were, however, hyperæmic, and the lungs exhibited œdema. S. B. S.

The Action on Man of Vapours of Technical and Hygienic Importance. XXXI. The "Nitrous Gases": Nitric Oxide, Nitrogen Dioxide, Nitrous and Nitric Acids. KARL B. LEHMANN and HASEGAWA (*Arch. Hygiene*, 1913, **77**, 323—368).—A summary is given of a number of cases in the literature describing the toxic symptoms produced in man by the "nitrous gases," which act essentially as a mixture of nitrous and nitric acid. Attention is called to the great differences as regards the susceptibility of

individuals to the poison. Experiments were carried out on animals with gas made by the action of nitric acid on copper. This was diluted with hydrogen, and mixed with air. An apparatus is figured to show how this was accomplished, and how samples of the air to which the animals were exposed could be removed for analysis. The analysis was accomplished by passing the air, first, over hydrogen peroxide, when the nitrous acid was oxidised to nitric acid, and the total nitrate, both preformed and produced by oxidation of the nitrous acid, was precipitated by nitron. The gas unabsorbed in the first absorption apparatus was passed through a second apparatus containing potassium iodide, and the iodine set free was titrated by thiosulphate solution. The general result of the experiments with mixtures of equimolecular proportions of nitrous and nitric acid is to show that the mixture acts as if all the nitrogenous products were in the form of nitric acid (see preceding abstract). In the majority of the animal experiments the toxic symptoms were different from those in man. These were generally only slight inflammatory reactions on the mucous membranes, œdema of lungs, in certain experiments, methæmoglobin formation, and indications of an action on the central nervous system. The temporary recovery after removal from the noxious vapours, with subsequent relapse, as is observed in the case of man, occurred only seldom in the case of animals. Experiments on man (Hasegawa), but carried out only with small doses of the noxious vapours, indicated that the symptoms were similar to those on animals. Various experiments were also carried out on the reduction of nitrate to nitrite by animal tissues, on the distribution of nitrites in tissues after injection into the trachæa, and on the toxic effect of nitrite administration. It was shown that the quantities of nitrite which produced severe symptoms after inhalation were far smaller than the quantities necessary to produce characteristic nitrite poisoning. The injurious effects in the inhalation experiments are to be ascribed to the production of the lung œdema. In man there is a latent period before the injurious effects are observed, which is generally absent in the case of animals.

S. B. S.

The Natural Resistance of the Hedgehog towards Certain Poisons M. A. WILLBERG (*Biochem. Zeitsch.*, 1913, **48**, 157—174).— It was found that the hedgehog could tolerate a dose of atropine sulphate 248 times larger (calculated per kilo. of body-weight) than that tolerated by man. The tolerance towards morphine hydrochloride was 245 times as greater; towards nicotine, 29 times; towards potassium arsenite, 10 times; towards curare, 7 times; towards potassium cyanide, 6 times; towards mercuric chloride, 4 times; and towards phenol, twice as great. There was no difference in the tolerance towards strychnine nitrate.   S. B. S.

Chemistry of Vegetable Physiology and Agriculture.

Bacterial Reduction of Sulphates to Sulphides. ERNST SALKOWSKI (*Zeitsch. physiol. Chem.*, 1913, **83**, 165—169).—Sasaki and Otsuka (A., 1912, ii, 475), working with 21 races of bacteria in pure culture, were unable to reduce sulphate to sulphide, and further state that bacteria produce no hydrogen sulphide from taurine.

Positive evidence is now quoted showing that in a great variety of cases bacteria relatively readily reduce sulphates to hydrogen sulphide.   E. F. A.

Bio-chemistry of Micro-organisms VII. The Fermentation of Formic Acid by Bacillus Kiliense in a Medium of Constant Composition. HARTWIG FRANZLN and F. EGGER (*Zeitsch. physiol. Chem.*, 1913, **83**, 226—228).—The paper consists chiefly of data obtained from experiments carried out on the same lines as those in which *Bacillus prodigiosus* was used (A., 1912, ii, 669). A slight production of formic acid occurs during the early stages of growth, after which fermentation takes place. The results show great divergence in the behaviour of the organism in different series of cultures, and general conclusions cannot be drawn.   H. B. H.

Action of Uranium Salts and Metallic Uranium on the Pyocyanic Bacillus. HENRI AGULHON and ROBERT SAZERAC (*Compt. rend.*, 1913, **156**, 162—164. Compare this vol., i, 143).—A study of the influence of uranium salts, soluble and insoluble, on the pyocyanic bacillus, the amount of pyocyanin formed being estimated colorimetrically, the culture medium used being hydrolysed serum. The toxic dose of uranyl acetate is 1 in 500, and of uranyl nitrate, 1 in 200. Doses of from 1 in 50,000 to 1 in 1000 are distinctly favourable, as was shown by the colour test, and also by the thickness of the microbic film produced. With insoluble uranium compounds, potassium or ammonium uranate, doses of 1 in 1000 to 1 in 100 gave an increase of 100% in the yield of pyocyanin, whilst in the case of the metal itself doses of 1% gave a decided growth within twenty-four hours in a medium to which the bacillus was not accustomed. The medium being neutral, this last effect could not be due to any of the uranium passing into solution, and finally favourable action was produced on the microbe in sealed tubes, the uranium being outside, thus pointing to the radioactivity of the uranium as being the cause of the increased growth in this and the previous cases.   W. G.

Influence of Salts of Uranium and Thorium on the Development of the Tubercle Bacillus. PAUL BECQUEREL (*Compt. rend.*, 1913, **156**, 164—166).—Radioactive salts of uranium and thorium behave physiologically like many other non-radioactive salts. They each have an optimum dose, which produces the

maximum growth of the bacillus, above which they begin to exert a toxic effect, uranyl nitrate being much more toxic than thorium nitrate. A dose of 1 in 2500 of the former has a marked inhibitory influence, whilst the same dose of the latter seems to be its optimum as regards increased microbic growth.   W. G.

Indole Reaction. HUGO ZIPFEL (*Centr. Bakt. Par.*, 1913, i, 67, 572—584. Compare A., 1912, ii, 793).—The contradictory results often yielded by the indole test may be attributed to unsuitability or variability of the medium. The use of a composite tryptophan medium with or without the addition of glycerol or dextrose is recommended, whereby trustworthy results can be obtained in twenty-four to forty-eight hours. Comparative tests of a large number of strains of certain pathogenic and non-pathogenic bacteria were made, and consistent results obtained with the various strains of each species of organism. The p-dimethylaminobenzaldehyde test for indole was found to be the most trustworthy.   H. B. H.

Mechanism of Alcoholic Fermentation. S. KOSTYTSCHEV (*Ber.*, 1913, 46, 339. Compare Kostytschev, A., 1912, ii, 589; Kostytschev and Hübbenet, *ibid*, 1912, ii, 860).—A claim for priority against von Lebedev (this vol., i, 144), in demonstrating that acetaldehyde is formed during the fermentation of sugar in the presence of zinc chloride, and, further, that acetaldehyde is reduced to ethyl alcohol by living yeast and various yeast preparations.   H. W.

Alcoholic Fermentation. III. Conditions Regulating the Formation of Acetaldehyde during the Fermentation of Hefanol (Yeast). S. KOSTYTSCHEV (*Zeitsch. physiol. Chem.*, 1912, 83, 93—104. Compare A., 1912, ii, 589; also Kostytschev and Hübbenet, A., 1912, ii, 860).—A reply to the criticisms of Neuberg and Kerb (A., 1912, ii, 973). Paracetaldehyde is very easily decomposed into acetaldehyde on distillation with traces of acid.

Autofermentation of yeast is a true alcoholic fermentation of the yeast glycogen; acetaldehyde is one of the products of the change. When fermentation of hefanol is effected in presence of sufficient methylene-blue to render the active reducing agent inoperative, acetaldehyde is formed as the normal reduction of acetaldehyde to ethyl alcohol is restricted.   E. F. A.

Biochemical Synthesis of Alkylglucosides (α-Glucosides) by means of a Ferment (α Glucosidase) contained in Air-dried Bottom Yeast. α-Ethylglucoside. ÉMILE BOURQUELOT, HENRI HÉRISSEY, and MARC BRIDEL (*Compt. rend.* 1913, 156, 168—170).—The authors have obtained α-ethylglucoside in a crystalline form, $[\alpha]_D$ +150·64°, by the action of a ferment, extracted from bottom yeast by water, on a dilute alcoholic solution of dextrose containing at least 65% of water by volume. The yield with respect to the dextrose used was 33%, and the glucoside was readily hydrolysed in aqueous solution by the same ferment, which they name α-glucosidase.   W. G.

Assimilation of Nitrate and Nitrite. V. Oskar Baudisch and Erwin Mayer (*Ber*, 1913, **46**, 115—125. Compare A, 1911, ii, 523; 1912, ii, 286, 1202).—When a dilute formaldehyde–potassium nitrate solution is exposed to sunlight a mixture of nitrous oxide and hydrogen, together with some carbon dioxide and monoxide, is evolved. In a formaldehyde-potassium nitrite solution, in addition, small quantities of nitric oxide are also formed. This originates from the decomposed nitroxyl NOH, a substance which does not exist as gas.

Angeli's salt, ONa·N:NO·ONa, decomposes on warming in aqueous solution into nitrous and nitric oxides and ammonia.

Solutions of potassium nitrite in either formaldehyde or methyl alcohol which have been exposed to light contain methylamine and, further, formic acid, hyponitrous acid, and hydroxylamine In addition an alkaloidal compound similar to nicotine and containing a pyrrole ring is formed. Whereas in the assimilation of carbon the carbonic acid is reduced to carboxylic acid by the yellow and red rays of the spectrum, in the assimilation of nitrogen the blue, violet, and ultra-violet rays cause the reduction of nitrates to nitroxyl.   E. F. A.

The Influence of Uranium and Lead on Vegetation. Julius Stoklasa (*Compt. rend.*, 1913, **156**, 153—155).—Uranyl nitrate added in small amounts to pot cultures of *Melilotus albus* already supplied with suitable fertilisers, had a favourable effect on the total yield of dry matter, the optimum quantity being 2·5 kilos. of uranium per hectare of soil. With 20 kilos. per hectare there was no indication of any toxic effect. The results with lead nitrate on oats and on *Polygonum fagopyrum* are of the same order, but the amount of lead which has an injurious effect is much less than in the case of uranium, the addition of lead nitrate at the rate of 8 kilos. per hectare being detrimental to the total crop in each case.   W. G.

The Cause of Growth in Plants. I. G. A. Borovikov (*Biochem. Zeitsch.*, 1913, **48**, 230—246). — The author reviews M. Fischer's experiments on the influence of acids, bases, and salts on various imbibition processes, for example, in gelatin and muscle. The view has been expressed by Fischer and others, that the phenomena of growth are determined, not so much by the osmotic properties of the cell, as by the capacity of the various colloids to imbibe water. The capacity is affected differently by various ions contained in the solution. The method of experiment employed by the author to investigate the various factors was as follows. Seedlings (six days old) of *Helianthus annuus* were placed in tubes which hung vertically in cylinders containing various solutions, and after intervals of three, six, and twelve hours and longer, removed, and the rate of growth was measured and compared with the rate of growth in pure water. The influence of various acids, bases, and salts on the rate of growth during short intervals was thus ascertained. It was found that acids accelerate the growth during the

first period, and if salts are present at the same time, the growth in the presence of both acid and salt is diminished as compared with that in acid alone.   The effect of the various ions and cations was studied in some detail, and attention is drawn to the parallelism between their influence on the rate of growth and their general effect on imbibition processes.   The experiments, generally, confirm the conception of the relationship between imbibition processes and growth.   S. B. S.

Presence of Formaldehyde in the Sap of Green Plants. FRANCESCO ANGELICO and G. CATALANO (*Gazzetta*, 1913, **43**, i, 38—43). —The formaldehyde which is supposed to be an intermediate product in the photosynthesis of starch in green plants has never been demonstrated in the sap with certainty.   The test for formaldehyde with atractylin (compare Angelico, A., 1910, i, 403) is not only very sensitive, but also specific.   The leaf-sap and its distillate of eleven species of green plants tested in this way showed the presence of formaldehyde, whilst the same products from six species previously kept for twenty-four hours in the dark gave no reaction. Three non-chlorophyllic, parasitic plants were also tested, and formaldehyde was found to be absent.   The results are therefore in complete agreement with the usual theory of photosynthesis.

R. V. S.

The Function of the Carboxylase in Plants.   W. ZALESKI and ELIZABETH MARX (*Biochem. Zeitsch.*, 1913, **48**, 175—180).—The seeds employed were sterilised with mercuric chloride, then dried and powdered.   The seeds of *Lupinus luteus* decompose free pyruvic acid as readily as they do its sodium salt.   Pea seeds, on the other hand, decompose the free acid less readily than its salt, a fact due probably to the alkalinity of the powder.   Seeds of *Vicia faba* only weakly attack the free acid, although they readily attack the sodium salt.   Lupine seeds can also attack pyruvic acid in a vacuum. Both pyruvic acid and its sodium salts inhibit the carbon dioxide production of the immature seeds.   Acetaldehyde could be detected in the experiments with both lupine and pea seeds when pyruvic acid was present.   It could be also detected, but in very much smaller quantities in the control experiments, in which the acid was absent.   The authors call attention to the parallelism of the actions of the seed carboxylase and of zymase, and discuss the rôle played by pyruvic acid in degradation of sugars and the production of ethyl alcohol.   S. B. S.

Rôle of Oxydases in the Formation of the Anthocyan Pigments of Plants.   FREDERICK KEEBLE and EDWARD FRANKLAND ARMSTRONG (*J. of Genetics*, 1912, **2**, 277—311.   Compare A, 1912, ii, 673).—The methods previously described for the localisation of oxydases have been extended to a variety of plants.   Peroxydase is shown to be more widely distributed than the organic peroxide which activates it.   The very general phenomenon of browning presented by dried plants is regarded as an indication of the presence

)f a complete oxydase. Exposure of plants to darkness leads to the formation of peroxide and to an increase of peroxydase. The bearing of these facts on the general metabolism in the plant is discussed.

E. F. A.

Colloidal Chlorophyll and the Shifting of the Absorption Bands in the Leaves of Living Plants. D. IVANOVSKI (*Biochem. Zeitsch.*, 1913, **48**, 328—331).—Herlitza has drawn the conclusion, from spectroscopic observations, that chlorophyll exists in the colloidal form in living plants. The author gives a table of extinction coefficients, and shows that those of the chlorophyll of the leaf fall between those of colloidal chlorophyll and of an alcoholic solution of the pigment. He draws attention to the fact that the chlorophyll in leaves exists, not evenly distributed, but in the chloroplasts, and that the absorption spectrum of the leaf combines the characters of an absorption and reflection spectrum. He shows that the absorption spectrum of the leaf can be closely imitated by the addition of electrolytes to colloidal chlorophyll. According to the size of the granula thus produced, the absorption band is shifted thereby towards the ultra-red. S. B. S.

Plant Fats. CARL THOMAE (*J. pr. Chem*, 1913, [ii], **87**, 144) — The fatty and waxy constituents of yeast, rose blossoms, and the skins of apples, grapes, peaches, potatoes, lemons, gherkins, and other parts of plants may be readily isolated in a state of purity by heating under diminished pressure. F. B.

The Non-Specificity of Zinc as a Biological Catalyst for the Culture of Aspergillus niger. CHARLES LEPIERRE (*Compt. rend.*, 1913, **156**, 258—261).—The author has tried the effect of replacing the zinc in Raulin's solution by cadmium on the cultivation of *Sterigmatocystis nigra*, and his results are not in accord with those recently put forward by Javillier (compare this vol., i, 235). On the contrary, he finds that cadmium replaces zinc perfectly in Raulin's solution, and, like it, plays a very energetic part in the rapid growth of the plant, being fixed by the plant. Further, he finds that zinc is not a specific catalyst for this culture, but can be replaced by other elements chemically analogous to it.

W. G.

Attempts to Substitute Glucinum for Magnesium and Zinc in the Culture of Sterigmatocystis nigra (Aspergillus niger). MAURICE JAVILLIER (*Compt. rend.*, 1913, **156**, 406—409. Compare this vol., i, 235).—A reply to Lepierre (preceding abstract). From further experiments the author maintains that glucinum cannot replace magnesium or zinc in the culture medium for *Aspergillus niger*, the magnesium being necessary as a nutrient and the zinc as a catalyst. He suggests that the difference between his and Lepierre's results may be due to the conditions of their culture media, or hereditary influences on the cultures. W. G.

Replacement of Zinc by Glucinum in the Culture of Aspergillus niger. CHARLES LEPIERRE (*Compt. rend.*, 1913, **156**, 409—411. Compare this vol., i, 235; preceding abstracts).—The results obtained are in direct opposition to those of Javillier (previous abstract). The author finds that the zinc in Raulin's liquid can be replaced by glucinum without affecting the weight of crop finally obtained from the culture of *Aspergillus niger* thereon, except that the maximum is somewhat retarded. This retardation is, however, only relative, and diminishes as the plant adapts itself to the new medium. Time, adaptation, and easy access of air play an important part in these cultures. The glucinum is fixed by the plant. W. G.

Formation of Urea by Two Moulds. ROBERT FOSSE (*Compt. rend.*, 1913, **156**, 263—265. Compare A., 1912, ii, 1203).— The author has isolated urea in small quantities in the form of its xanthhydrol derivative from the expressed juice of mycelium gathered from the surface of Raulin's liquid and also from *Aspergillus niger* grown on a solution in which ammonium nitrate has replaced the chloride in Raulin's liquid. *Penicillium glaucum* similarly contains small quantities of urea in its cells. From his results the author draws the conclusion that the principal factor in ureogenesis is a process of oxidation, and not, as at present supposed, a diastatic oxidation. W. G.

The Nitrogenous Constituents of Lime Juice. CASIMIR FUNK (*Biochem. J.*, 1913, **7**, 81—86).—In view of work on beri-beri, in which the physiological importance of certain substances (probably pyrimidine derivatives) has been shown, lime juice was examined in reference to scurvy. Lime juice cures scurvy, and also contains an antineuritic substance. Pyrimidine substances in general prolong life in birds with polyneuritis. No anti-scorbutic substance, however, was separated out from lime juice. The investigation was hampered by the guinea-pigs refusing to take oats, a diet which leads to scurvy in these animals. Milk prevents oats from causing scurvy, even though the proteins are removed. The anti-scorbutic material in milk is destroyed by a high temperature. Its unstable character may have led to the negative results with lime juice. Several new compounds were, however, separated from lime juice; one, $C_{13}H_{24}O_3$, needles, m. p. 97 –100°, apparently belongs to the terpene group; one, $C_6H_7O_2N_5$, crystalline plates, m. p. 282° (corr.), to the purine group; one, $C_9H_{18}O_6N_2$, microscopic spherolites, m. p. 188—189° (decomp.), to the pyrimidine group; and a fourth to the choline group; the latter crystallised in cubes, and gave a platinichloride, $(C_8H_{17}O_2N)_2H_2PtCl_6$, m. p. 220°. The phosphotungstic and silver nitrate precipitates were mainly examined. W. D. H.

Constituents of Apples. CARL THOMAE (*J. pr. Chem.*, 1913, [ii], **87**, 142—144).—The substance, m. p. above 200°, previously isolated by the author (A., 1911, ii, 920) from apple-skins may be separated

by treatment with ether into an insoluble substance of high melting point, and a waxy substance crystallising in needles, m. p. 68·5°. On distillation under diminished pressure, the oil obtained by extracting the skins with ether yields a crystalline substance of low melting point having an odour of apples and a yellow oil which readily solidifies. The behaviour of the skins on distillation is also described.   F. B.

Leaves of Barosma venusta. HAROLD R. JENSEN (*Pharm. J.*, 1913, [iv], **36**, 60—61).—This material from Cape Province, South Africa, yielded 1·1% of volatile oil, $D_{15.5}^{15.5}$ 0·8839, $a_D^{20} + 0°30'$, n_D^{20} 1·4967, of greenish-yellow colour, and having acid value 2·4 and saponification value 13·4. On treatment with potassium hydroxide solution, 16% of the oil dissolved, and a further 4% was absorbed by a solution of neutral sodium sulphite. The oil was separated into nine fractions by distillation under reduced pressure, and the physical constants, ultimate composition, and reactions with bromine, sodium, and phenylhydrazine of each fraction are recorded. From a consideration of these data the following composition is tentatively suggested for the oil: myrcene, 35; chavicol, 16; myrcenol and sesquiterpene alcohols, 15; methylchavicol and anethole, 15; sesquiterpenes, esters, ketones, aldehydes, and acids, 19%. The leaves also contain oleoresin, acid resins, colourless glucosides, fat, carbohydrates, and a little tannin. The results show that these leaves do not contain the same constituents as the commercial buchus derived from *B. betulina* and *B. serratifolia*, and that they cannot be used in medicine in place of these.
                                                        T. A. H.

Constituents of Lycoperdon bovista. JAN J. BLANKSMA (*Chem. Weekblad*, 1913, **10**, 96—100).—Fresh specimens of the edible mushroom, *Lycoperdon bovista*, contain trehalose, tyrosine, a substance with m. p. 165°, chitin, and leucine, all previously isolated (compare Bourquelot, *J. Pharm. Chim.*, 1907, [vi], **25**, 382; Bamberger and Landsiedl, A., 1903, ii, 567; 1905, ii, 852). The trehalose is converted by trehalase, invertase, and diastase into reducing sugars, these ferments being present in the mushrooms. The darkening in colour of mushrooms is explained by the conversion of tyrosine into melanin, a black substance, under the influence of tyrosinase It is possible that leucine is converted into *iso*amylamine, and the tyrosine into *p*-hydroxylphenylethylamine, a substance of very poisonous character. It is known that old specimens of *Lycoperdon bovista* are poisonous. The author recommends the preparation of glucosamine hydrochloride by boiling mushrooms with dilute hydrochloric acid after elimination of proteins, fats, and calcium salts.   A. J. W.

Organic Chemistry.

Notes on Mine Gas Problems. GEORGE A. BURRELL (*J. Ind. Eng. Chem.*, 1913, 5, 181—186).—The author gives an account of the various problems met with in connexion with mine gases, interpolating from time to time some of the data accumulated by the Bureau of Mines with respect to the explosibility and physiological effects of mine atmospheres, and to flame extinction and after-damp.

The lower explosive limit of mixtures of air and methane is confirmed to be 5·5% methane. The presence of carbon dioxide alters this explosive limit, but even 10% of carbon dioxide raises it only to 6·6%. Reduction in the volume percentage of oxygen also raises the explosive limit. Harger has suggested that a small reduction in the oxygen percentage and a small increase in the carbon dioxide percentage in mine air will suffice to produce an atmosphere incapable of supporting combustion, and consequently an atmosphere in which explosions and gob fires cannot occur, but the data obtained by the Bureau of Mines indicate that the figures given by Harger are much too low, both with respect to the increase in carbon dioxide and diminution in oxygen.

When acetylene is used in the miner's lamp, the flame resembles the ordinary wick flame burning in pure air, when the oxygen content of the air decreases to 16—16·5%; this behaviour of the flame can be used as a guide to men venturing into workings containing black damp and less oxygen than the percentage given. The ordinary miner's lamp is extinguished when the oxygen falls to about 16·5—17%; the extinguishing of the flame is shown to be due to deficiency in oxygen and not to the presence of carbon dioxide.

Reference is made to the following subjects: Effect of vitiated air on the luminosity of miner's lamps (compare Haldane, *Colliery Guardian*, Oct. 25th, 1912); high velocity of air currents in mines; distribution of after-damp; intrusion of natural gas into mines, etc. Analyses are also given of mine-gas mixtures containing explosive and other proportions of methane, and of samples of after-damp atmospheres which show the large amount of carbon monoxide (white-damp) present shortly after an explosion. T. S. P.

Solvents for Acetylene. JOSEPH H. JAMES (*J. Ind. Eng. Chem.*, 1913, 5, 115—120).—An investigation of the solvent powers for acetylene of a number of organic liquids shows that those containing the carbonyl group are generally the best solvents. Organic acids must be excluded, however, the hydroxyl in the carboxyl group seeming to inhibit the solvent action of the carbonyl. The presence of the carbonyl group is not sufficient, of itself, to account for the solubility, since methylal and acetal are very good solvents.

It is found that acetaldehyde fulfils all the industrial requirements for an acetylene solvent. T. S. P.

Preparation of Dimethylacetylene [Crotonylene] and Ethyl-acetylene from Carbides. CARL WILLI SCHLUCHTER (D.R. P. 253802).—When methyl alcohol is heated with an alkaline earth carbide during four days at 60—120° under a pressure of 50 atmospheres, or during six days in a closed tube at 200° it yields a mixture of crotonylene (Δ^β-butinene), $CMe\vdots CMe$, b. p. 28°, and ethylacetylene [Δ^a-butinene], $CEt\vdots CH$, b. p. 18°.   F. M. G. M.

Δ^{ayc}-Heptatriene and Related Substances. CORNELIS J. ENKLAAR (*Chem. Weekblad*, 1913, 10, 187—189. Compare this vol., i, 243).—A discussion of the influence of structure on the possibility of solidifying unsaturated hydrocarbons. By cooling with liquid air several butadienes and related substances have been converted into the solid state.   A. J. W.

Vinylacetylene. RICHARD WILLSTÄTTER and THEODOR WIRTH (*Ber.*, 1913, 46, 535—538).—By the action of dimethylamine in benzene solution on the dibromide of butadiene, $a\delta$-tetramethyl-diamino-Δ^β-butylene, $NMe_2 \cdot CH_2 \cdot CH\vdots CH \cdot CH_2 \cdot NMe_2$, is obtained. The use of an indifferent solvent, such as benzene, is essential; with alcohol numerous secondary reactions take place.

When the corresponding diquaternary ammonium base is distilled in a vacuum it is decomposed, and vinylacetylene, $CH\vdots C \cdot CH\vdots CH_2$, is obtained.

$a\delta$-*Tetramethyldiaminobutylene* is a colourless oil with a narcotic odour, b. p. 171—172°/723 mm., 65—65·5°/17 mm., D_4^0 0·8198. The *picrate* forms needles, m. p. 222—223°; the *aurichloride* separates in crystalline needles, m. p. 201° (decomp.); the *platinichloride*, $2H_2O$, crystallises in long, rhombohedric prisms, m. p. 227—228°, whilst the *dimethiodide* forms prisms, decomp. 270°.

Vinylacetylene [$\Delta^{a\gamma}$-*buteninene*] melts to a colourless liquid, b. p. 2—3°/729 mm., and has an odour like acetylene. It forms a greenish-yellow copper salt and a colourless, crystalline silver salt, which explodes when heated.   E. F. A.

A Catalytic Method of Isomerisation of Alkyl Chlorides and Bromides. PAUL SABATIER and ALPHONSE MAILHE (*Compt. rend.*, 1913, 156, 658—659. Compare A., 1905, i, 677).—Barium chloride or thorium chloride at 250° causes the decomposition of primary alkyl chlorides or bromides into ethylene hydrocarbons and hydrogen chloride or bromide. These then recombine, when passed over pumice stone at 200°, giving, not the original haloid, but the isomeric chloride or bromide. The resulting liquid is submitted to fractional distillation, thus separating any of the original unchanged substance.   W. G.

Trichloroethylene and Some of its Derivatives. JACOB BOESEKEN [with C. E. KLAMER and J. G. DE VOOGT] (*Rec. trav. chim.*, 1913, 32, 15—22).—Unsuccessful attempts have been made to bring trichloroethylene and tetrachloroethylene into reaction with benzoyl chloride, sulphur chloride, phosphorus chloride, thionyl chloride, and

sulphuryl chloride respectively in the presence of aluminium chloride. Charred products were obtained, except in the case of tetrachloroethylene and sulphuryl chloride, when hexachloroethane was isolated, owing to the decomposition of sulphuryl chloride into sulphur dioxide and chlorine and union of the latter with tetrachloroethylene.

Barium monochlorosulphoacetate, C_2HO_5ClSBa, was isolated from the product of the action of fuming sulphuric acid (containing 10% SO_3) on trichloroethylene at 88°.

When trichloroethylene was added drop by drop to a mixture of nitric acid (D 1·5) and concentrated sulphuric acid, cooled by a freezing mixture of salt and ice, and the action interrupted as soon as the temperature of the product rose but slowly when removed from the freezing mixture, dichloroacetic acid was obtained, together with a *substance*, $C_2HO_8N_2Cl_3$, b. p. 32°/36 mm., which, when preserved, became converted into colourless, very hygroscopic needles, which were insoluble in, or decomposed by, the ordinary solvents, and had mol. wt. 194 in nitrobenzene solution. When heated with hydrochloric acid, this substance yielded small amounts of nitric oxide and carbon dioxide, but neither hydroxylamine nor oxalic acid could be detected. Alcoholic potassium hydroxide decomposed it according to the equation: $C_2HO_8N_2Cl_3 + 7KOH = 3KCl + 2K_2CO_3 + 4H_2O + N_2$. With zinc and cold dilute sulphuric acid it gave a quantitative yield of ammonia. It did not give Liebermann's reaction. In view of the above properties, the annexed formula is tentatively proposed for it. H. W.
$$\begin{array}{l} Cl_2C\text{-}O\text{-}N \\ \quad |\diagup O| \\ ClO\text{-}O\text{-}NH \end{array}$$

Elimination of Water from Pinacolyl Alcohol. Tertiary Butylethylene. W. FOMIN and N. SOCHANSKI (*Ber.*, 1913, **46**, 244—248).—Pinacolyl alcohol was converted by Couturier (A., 1893, i, 245) into a bromide, which, when treated with solid potassium hydroxide, gave a mixture of $\beta\gamma$-dimethyl-Δ^β-butylene (compare Zelinsky and Zelikov, A , 1902, i, 2) with a small quantity of a hydrocarbon, b. p. 56—59°, which was described as *tert.*-butyl ethylene. The latter compound has now been prepared from pinacolyl alcohol by Tschugaev's method and has other properties.

The potassium derivative is prepared by adding the alcohol to potassium *tert*-amyloxide (compare Tschugaev, A., 1905, i, 167) and then treated with carbon disulphide and methyl iodide. The *methyl pinacolyl xanthate*, C_6H_{12}·O·CS·SMe, b. p. 100°/12 mm., D_4^{10} 1·0228, decomposes at 160—175°, and the purified *tert.-butylethylene* [$\gamma\gamma$-*dimethyl-Δ^α-butylene*], CMe_3·CH⫶CH$_2$, is a colourless liquid, having b. p. 41·2°/760 mm., D_4^{10} 0·6549, and n_D 1·37667. On oxidation with permanganate, acetone is not obtained, the chief product being $\alpha\alpha$-dimethylpropionic acid, whilst reduction with hydrogen in presence of platinum black results in the formation of $\beta\beta$-dimethylbutane.

J. C. W.

Decomposition of Heptyl Alcohol at 220° in the Presence of Finely Divided Nickel. JACOB BÖESEKEN and G. H. VAN SENDEN (*Rec. trav. chim.*, 1913, **32**, 23 38).—The authors have repeated the

experiments described by van Beresteyn (A., 1911, i, 761), who obtained heptyl alcohol and a substance which he regarded as *n*-hexylene, by the reduction of heptaldehyde according to the general method of Sabatier and Senderens. Heptyl alcohol, under similar circumstances, was found to yield *n*-hexylene, carbon monoxide, and hydrogen, the course of the actions being represented by the equations: $C_6H_{13}\cdot CHO + H_2 = C_7H_{15}\cdot OH$. $C_7H_{15}\cdot OH = C_6H_{12} + CH_3\cdot OH$. $CH_3\cdot OH = CO + 2H_2$. On theoretical grounds, the authors consider this interpretation to be improbable, and are led to the conclusions : (1) that heptyl alcohol, in the presence of finely divided nickel at 220°, is decomposed into heptaldehyde and hydrogen ; (2) that, particularly in the presence of an inert gas, the heptaldehyde is converted into *n*-hexylene, hydrogen, and carbon monoxide ; (3) that *n*-hexylene combines with a considerable proportion of the liberated hydrogen to form *n* hexane, and that, in the presence of an excess of hydrogen, all the *n*-hexylene undergoes reduction ; (4) that heptaldehyde is not reduced in the presence of carbon dioxide, and only slightly reduced in an atmosphere of hydrogen ; (5) that *n*-hexylene (mixed with *n*-hexane) is best obtained by the decomposition of heptaldehyde by nickel at 220° in a current of carbon dioxide, and (6) that *n*-hexane is obtained by the catalytic decomposition of heptyl alcohol or heptaldehyde by nickel at 220° in a current of hydrogen.

Heptyl alcohol was obtained by the reduction of heptaldehyde dissolved in glacial acetic acid by means of sodium amalgam. Small quantities of s-*di-n-hexylethyleneglycol* [*n-tetradecane-ηθ-diol*], b. p. 218°/14 mm., m. p. 69—70°, were obtained as by-product.

Heptyl alcohol, when passed over nickel at 220° in a current of hydrogen, yielded about 62% *n*-hexane, 17% of a mixture of heptyl alcohol and heptaldehyde, and carbon monoxide. In a current of carbon dioxide, however, it yielded about 14·5% *n*-hexylene, 31% *n*-hexane, 24% of a mixture of heptyl alcohol with a little heptaldehyde, carbon monoxide, and hydrogen, the change being represented by the equation : $3C_7H_{15}\cdot OH = 2C_6H_{14} + C_6H_{12} + 3CO + 4H_2$.

Heptaldehyde, at 220° in a current of carbon dioxide, gave about 24% *n*-hexylene, 29% *n*-hexane, 16% unchanged heptaldehyde, carbon monoxide, hydrogen, and possibly a trace of formaldehyde. The quantities of the products obtained agreed with the equation : $100C_6H_{13}\cdot CHO = 45C_6H_{12} + 55C_6H_{14} + 100CO + 45H_2$. At 180°, the course of the reaction was similar.

n-Hexane was not affected when passed over nickel at 220° in a current of carbon dioxide.   H. W.

aδ-Oxide from Undecyl Alcohol. N. A. LOGGINOV (*J. Russ. Phys. Chem. Soc.*, 1913, 45, 136—145)—The action of zinc chloride or 50% sulphuric acid on undecyl alcohol results in displacement of the double linking of the alcohol and formation of the aδ-*oxide*,

$$CH_3\cdot[CH_2]_6\cdot CH{<}^{OH:CH}_{O—CH_2},$$ b. p. 219—222°, D_0^0 0·8641 (or 0·8667), D_0^{17} 0·8522, D_0^{18} 0 8538.

When zinc chloride is used, the oxide is accompanied by an unsaturated *alcohol*, $C_{11}H_{22}O$, b. p. 243—246°, which forms a crystalline *phenylurethane*, $C_{18}H_{27}O_2N$, m. p. 49·5°, and is being further investigated. T. H. P.

Action of αβ-Dichloroethyl Ether on Mixed Magnesium Derivatives. ROBERT LESPIEAU and BRESCH (*Compt. rend.*, 1913, **156**, 710—712).—αβ-Dichloroethyl ether condenses readily with magnesium derivatives of ethyl and allyl bromides and acetylene, giving products somewhat difficult to purify. The *compound*,
$$C_{10}H_{16}O_2Cl_2,$$

obtained from the acetylene derivative is a colourless liquid, b. p. 136—137°/12 mm., and is probably a mixture of two *cis-* and *trans-*isomerides (compare Dupont, A., 1910, i, 85). On bromination in chloroform, it yields two *dibromides*, $C_{10}H_{16}O_2Cl_2Br_2$, separable by their varying solubility, the less soluble one having m. p. 107—108°, and the other m. p. 71—72°. These are also probably *cis-* and *trans-*isomerides. W. G.

Compounds of Ethyl Phosphite with Silver Haloids. ALEXANDER E. ARBUZOV and A. V. KARTASCHOV (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 79—81).—Derivatives of tervalent phosphorus of the form PR_3 or $P(OR)_3$ form compounds with cuprous and platinous haloids, and the authors find that ethyl phosphite forms similar compounds with silver haloids. These compounds form colourless, ribbon-like crystals, their melting points being: $P(OEt)_3,AgCl$, 4·5—5·5°; $P(OEt)_3,AgBr$, 40—40·5°; $P(OEt)_3,AgI$, 81—83°. T. H. P.

Uranium Formate. WILLIAM OECHSNER DE CONINCK and ALBERT RAYNAUD (*Bull. Soc. chim.*, 1913, [iv], **13**, 221—223).—Uranium formate is a deliquescent, yellow salt, readily soluble in water. Attempts to estimate the water of crystallisation were unsuccessful, owing to the ready loss of formic acid from the salt on prolonged desiccation. When calcined in a closed vessel, the salt leaves a residue of pure uranous oxide, but, if an open vessel is used, traces of a higher oxide are formed. Similar results were previously obtained with uranium oxalate (A., 1912, i, 535).

When boiled with a large quantity of water, uranium formate is hydrolysed, hydrated uranium trioxide, $UO_3,2H_2O$, separating as a yellow precipitate, which is converted by calcination into the green oxide, U_3O_8.

Uranium formate was exposed to diffused daylight during three months in the presence of methyl alcohol. A brown deposit of uranium oxide was thereby obtained, and the strongly acid methyl alcoholic solution was found to contain methyl formate.

Very little decomposition occurred in similar circumstances in the presence of ethyl alcohol. Very little formic acid was liberated, whilst the residue contained only small amounts of mono- and di-hydrated uranium trioxide mixed with unchanged uranium formate. H. W.

Preparation of Halogen Formic Esters. EMANUEL MERCK (D.R.-P. 254471).—The following halogen formic esters in addition to those previously described (this vol., i, 5) have now been prepared. *Dimethylethylcarbinyl chloro-formate*, a liquid which decomposes at 20° and cannot be distilled in a vacuum ; the homologous *methyldiethylcarbinyl chloro-formate* has similar properties.   F. M. G. M.

Distillation and Sublimation of Ammonium Salts under Diminished Pressure. RICHARD ESCALES and HANS KOEPKE (*J. pr. Chem*, 1913, [ii], 87, 258—279).—Of the normal salts examined the formate (*s*, 90—140°), acetate (*s*, 90°), thiocyanate (*d*, 165°), cyanate (*s*, 160—190°), nitrite (*s*, 70°), and sulphite (*s*, 70—120°) distil or sublime under a pressure of 10 mm. without decomposition, whilst the propionate (*d*, 70—75°), butyrate (*d*, 70—80°), glycollate (*d*, 160°), lactate (*d*, 140—150°), benzoate (*s*, 60—130°), and salicylate (*s*, 90—150°) are converted into the corresponding acid salts, NH_4HX_2 ; the temperatures at which distillation or sublimation occurs are given in brackets (*s* denotes sublimation ; *d*, distillation).   When heated to 300°/10 mm., ammonium sulphate and persulphate lose ammonia, yielding the acid salts; ammonium thiosulphate sublimes at 70°/10 mm., the sublimate consisting of ammonium sulphite.   Ammonium carbonate undergoes complete dissociation, whilst carbamide and thiocarbamide sublime in .the form of ammonium cyanate and thiocyanate respectively.   Of the acid salts, NH_4HX_2, the acetate (*d*, 67°), propionate (*d*, 73°), butyrate (*d*, 78°), glycollate (*d*, 160°), lactate (*d*, 145°), benzoate (*s*, 60—130°), salicylate (*s*, 90—150°), and hydrogen carbonate distil or sublime unchanged at 10 mm.

A mixture of normal or acid ammonium acetate and propionic acid in molecular proportions distils at 66—68°/10 mm., yielding the acid *ammonium* salt, $CH_3 \cdot CO_2 \cdot NH_4, C_2H_5 \cdot CO_2H$, which forms very deliquescent crystals, m. p. 42—43°, and is converted by distillation with butyric acid into the *ammonium* salt, $CH_3 \cdot CO_2 \cdot NH_4, C_3H_7 \cdot CO_2H$. This has m. p. 41°, b. p. 72—74°/10 mm., and is also obtained by distilling normal or acid ammonium acetate with butyric acid.   F. B.

Decomposition of Certain Acid Chlorides by Aluminium Chloride. JACOB BOESEKEN (*Rec. trav. chim.*, 1913, 32, 1—14) ·· In continuation of the work of Böeseken and Prins (A., 1910, i, 152; 1911, i, 173), the action of aluminium chloride on the chlorides or sulphonyl chlorides of a number of halogenated acids has been investigated.   Normal results were obtained with acid chlorides which did not contain hydrogen or a benzene group, but, in the presence of the latter, the reaction appeared to be complex, giving resinous products from which no definite compound could be isolated.

[With P. HASSELBACH.]—Monochloroacetyl chloride and aluminium chloride yielded a hygroscopic, crystalline *compound*,
$$CH_2Cl \cdot COCl, AlCl_3,$$
which, when heated alone or with carbon tetrachloride, evolved hydrogen chloride, leaving a charred residue.   Carbon monoxide could not be detected in the gas evolved.   When heated in chloroform solution at 80°, a small quantity of a *substance*, m. p. about 175°, was obtained, to
which no definite composition could be assigned. Similarly, aluminium chloride and chlorofumaryl chloride or $a:\beta:\beta:\beta$-tetrachloropropionyl chloride yielded only charred or resinous products, from which a definite compound could not be separated.

[With (Mlle.) S. VAN DER TAS]—*p*-Chlorobenzenesulphonyl chloride and aluminium chloride gave resinous products. The gases evolved contained hydrogen chloride and, generally, sulphur dioxide.

[With W. J. P. PELLE.]—*p*-Bromobenzenesulphonyl chloride and aluminium chloride yielded a crystalline additive product,

$$C_6H_4Br\cdot SO_2Cl,AlCl_3,$$
which, when heated at 150—200°, evolved sulphur dioxide and hydrogen chloride, and left a brown resin.

[With P. HASSELBACH.]—*Trichloroacrylyl chloride*, b. p. 158°/760 mm., was obtained by the action of thionyl chloride on trichloroacrylic acid. When mixed with aluminium chloride in carbon disulphide solution, it yielded the *compound*, $CCl_2:CCl\cdot COCl,AlCl_3$, which, when heated in a current of dry air, gave only trichloroacrylyl chloride mixed with a little aluminium chloride, but no carbon monoxide. In the presence of aluminium chloride, trichloroacrylyl chloride reacted with benzene and its homologues to form quantitative yields of ketones of the type $R\cdot CO\cdot CCl:CCl_2$, only the chlorine atom attached to the carbonyl group being replaced.

Pentachloropropionyl chloride, m. p. 42°, obtained from the preceding chloride by the action of chlorine in sunlight, when heated with aluminium chloride at 60° evolved carbon monoxide and carbonyl chloride, leaving a residue from which hexachloroethane and tetrachloroethylene were isolated, decomposition occurring according to the equations: (I) $CCl_3\cdot CCl_2\cdot COCl = CO + C_2Cl_6$. (II) $CCl_3\cdot CCl_2\cdot COCl = COCl_2 + C_2Cl_4$. When treated with aluminium chloride in the presence of benzene, *pentachloropropiophenone*, $COPh\cdot CCl_2\cdot CCl_3$, m. p. 83°, was obtained when the reaction was continued until one molecule of hydrogen chloride had been evolved. When, however, reaction was continued until two molecules of hydrogen chloride had been evolved, tetrachloroethylene and benzophenone were formed. The presence of the latter may be due to dissociation of pentachloropropionyl chloride into tetrachloroethylene and carbonyl chloride, and condensation of the latter with benzene, or pentachloropropiophenone may be decomposed by aluminium chloride into tetrachloroethylene and benzoyl chloride. The odour of the latter is perceptible when pentachloropropiophenone is warmed with a little aluminium chloride.   H. W.

Montanic Acid and its Derivatives. HUGH RYAN and JOSEPH ALGAR (*Proc. Roy. Irish Acad.*, 1913, **30**, 97—105. Compare A., 1909, i, 629).—The authors have prepared a series of derivatives of montanic acid, the formulæ of which are in agreement with the formula, $C_{29}H_{58}O_2$, for montanic acid itself, thus confirming the previous work of Ryan and Dillon (A., 1909, i, 629), and Easterfield and Taylor (T., 1911, 99, 2302), in contrast to that of Holl (*Zeitsch angew. Chem.*, 1900, **13**, 556), von Boyen (A., 1902, i, 72), and Eisenreich.

Methyl montanate, prepared by boiling montanic acid with methyl

alcohol in the presence of sulphuric acid, crystallises in white, curved needles, m. p. 66°. The similarly crystallised *ethyl* and n *propyl* esters have m. p. 64—65° and 63·5° respectively.

Dimethylheptacosylcarbinol, $C_{27}H_5$,·CMe_2·OH, obtained from methyl montanate and magnesium methyl iodide, has m. p. 63—64°, whilst the corresponding *diethyl* and *diphenyl* derivatives melt respectively at 59—60° and 58°. When ethyl montanate is treated with *p*-bromotoluene and the resulting product subjected to steam distillation, the residue is found to consist of the unsaturated *hydrocarbon*, $C_{27}H_{54}$·$C(C_6H_4Me)_2$, m. p. 47°. When, however, the steam distillation is omitted and the product purified by repeated crystallisation from alcohol, it can be separated into two portions, the major part consisting of the above hydrocarbon, the minor part of *di-p-tolylheptacosyl-carbinol*, m. p. 51—52°. The action of an ethereal solution of magnesium α-naphthyl bromide on ethyl montanate appears to yield a mixture of *di-α-naphthylheptacosylcarbinol*, m. p. 57—58°, and, probably, *α-naphthyl-heptacosyl ketone*, $C_{27}H_{55}$·CO·$C_{10}H_7$, m. p. 51—53°. These substances can be readily separated, since the former dissolves very sparingly in hot methyl alcohol, in which the latter is readily soluble.

Unsuccessful attempts were made to isolate *montanyl chloride* in the pure state by the action of phosphorus tri- or penta-chloride on montanic acid. The product obtained had m. p. 63—65°. It was transformed by concentrated aqueous ammonia into *montanamide*, m. p. 109°, small quantities of a *substance*, probably montanonitrile, m. p. 60—65°, being simultaneously formed.

Attempts to prepare ceryl alcohol from montanic acid were unsuccessful, owing to the difficulty of isolating *heptacosylmethylurethane* from the product of the successive action of bromine and sodium methoxide on montanamide. The converse operation (the preparation of montanic acid from ceryl alcohol by the malonic ester synthesis) could not be effected, since cerylmalonic ester could not be obtained from ceryl iodide and sodiomalonic ester under the most varied conditions. *Ceryl iodide*, $C_{26}H_{51}I$, m. p. 55—56°, was obtained by the action of iodine and red phosphorus on ceryl alcohol.   H. W.

Action of Thionyl Chloride on Certain Lactones. PHILIPPE BARBIER and RENÉ LOCQUIN (*Bull. Soc. chim.*, 1913, [iv], 13, 223—229).—A critical survey of the action of thionyl chloride on organic substances is given. The authors have investigated the effect of boiling certain γ-lactones (1 mol.) in benzene solution with thionyl chloride (1·1 mol.). The product of the reaction was poured into excess of methyl or ethyl alcohol and subsequently examined in the form of its methyl or ethyl ester. In these circumstances, thionyl chloride transforms the γ-lactones employed (except coumarin) into esters of γ-hydroxy-acids according to the scheme :

$$R·\overset{|}{C}H·CH_2·\overset{|}{C}H_2 \xrightarrow{SOCl_2} R·\overset{|}{C}H·CH_2·CH_2·COCl \xrightarrow{2C_2H_5OH}$$
$$O\text{————}CO \qquad\qquad O·SOCl$$

$$R·\overset{|}{C}H·CH_2·CH_2·CO_2Et + SO\overset{OEt}{\underset{Cl}{<}} + HCl.$$
$$OH$$
γ-Valerolactone was transformed into ethyl γ-hydroxyvalerate,

b. p. 80—81°/12 mm. (compare Neugebauer, A., 1885, 651), from which a phenylurethane could not be obtained.

γ-Phenyl-γ-butyrolactone, m. p. 37—38°, b. p. 175—176°/11 mm. (Jayne, A., 1883, 472; Fittig and Leoni, A, 1898, i, 196), was prepared by the condensation of bromo-acetophenone with ethyl sodiomalonate and saponification of the crude product with alcoholic sodium hydroxide at 160°. At the high temperature employed, the latter substance probably acted as a reducing agent. In addition, small quantities of benzoylpropionic acid and of a neutral *substance*, m. p. 190—192°, probably a dilactone (annexed formula), were obtained. When acted on successively by thionyl chloride and ethyl alcohol, γ-phenyl-γ-butyrolactone yielded *ethyl γ-hydroxy-γ-phenylbutyrate*, b. p. 158—160°/17 mm.
Coumarin did not react with thionyl chloride under the conditions employed. H. W.

Action of Thionyl Chloride on Certain Lactonic Acids. PHILIPPE BARBIER and RENÉ LOCQUIN (*Bull. Soc. chim*, 1913, [iv], 13, 229—236. Compare preceding abstract).—The experimental conditions chosen were the same as those previously described (*loc. cit.*). In these circumstances, thionyl chloride does not cause a rupture of the lactonic grouping, the product of the reaction being the lactonic acid chloride. This result is not influenced by the use of an excess of thionyl chloride.

Methylparaconyl chloride, b. p. about 142°/10 mm., obtained by the action of thionyl chloride on methylparaconic acid, was converted by methyl alcohol into *methyl methylparaconate*, b. p. 145—146°/11 mm.

In similar circumstances, terebic acid slowly yielded the corresponding chloride, b. p. 143°/12 mm., from which *methyl terebate*, b. p. 148—149°/17 mm, was obtained.

ββ-Dimethylbutyrolactone γ carboxylic acid (Perkin and Thorpe, T., 1899, 75, 56) gave the corresponding chloride, which, when treated with methyl alcohol, yielded the *methyl* ester, b. p. 149—150°/12 mm.

Similarly, terpenylic acid formed terpenyl chloride, methyl terpenylate, b. p. 145—147°/15 mm., and ethyl terpenylate, m. p. 37·5°, b. p. 174—177°/15 mm. Fittig and Levy (A., 1890, 873) give b. p. 305°/ordinary pressure, whereas Simonsen (T, 1907, 91, 187) found 169—171°/15 mm.

Phenylparaconyl chloride, prepared by the action of thionyl chloride on anhydrous phenylparaconic acid, m. p. 106°, 115°, or 121° (compare Jayne, A., 1883, 473; Fittig and Röders, A., 1890, 621) yielded, when decomposed by water, the acid, m. p. 99°. With methyl alcohol it yielded *methyl phenylparaconate*, m. p. 69—70°, b. p. 211°/14 mm. In the case of phenylparaconic acid, small quantities of polyphenylcrotonic acid, m. p. 179°, were also isolated.

The authors have attempted unsuccessfully to repeat the previously recorded transformation of terebic and phenylparaconic acids into the

anhydrides of *cis*-3 : 3-dimethyl*cyclo*propane-1 : 2-dicarboxylic acid and *cis*-3-phenyl*cyclo*propane-1 : 2-dicarboxylic acid (A., 1911, i, 722) under the action of thionyl chloride. They now attribute this result to the presence of some impurity in the specimen of thionyl chloride used, and point out that the substance is frequently contaminated with phosphoryl chloride, stannic chloride, sulphur trioxide, etc., to the presence of which the irregular results frequently obtained by the application of the reagent are ascribed.   II. W.

$\gamma\gamma\gamma$-Trichloro-β-hydroxybutyric Acid and $\gamma\gamma\gamma$-Trichloro-crotonic Acid. KARL VON AUWERS and M. SCHMIDT (*Ber*, 1913, 46, 487—494. See following abstract).—$\gamma\gamma\gamma$-Trichloro-β-hydroxy-butyric acid, m. p. 118—119° (von Thurnlackh, A., 1892, 429), is best obtained by gently boiling a mixture of malonic acid, chloral, and acetic acid for several hours; a certain specimen of malonic acid, although apparently normal in all other respects, always failed to give this reaction. The substance can be distilled almost undecomposed in small quantities, b. p. 181—188°/17 mm.; methyl ester, rhombohedral crystals, m. p. 61—62°, b. p. 135—136°/13 mm.; *ethyl* ester, silky needles, m. p. 56—57°, b. p. 143—144°/12 mm.; the *acetyl* derivative, needles, m. p. 97—99°, gives an oily *methyl* ester, b. p. 130°/13 mm., D_4^{143} 1·3937, n_D^{145} 1·46815, and an oily *ethyl* ester, b. p. 134°/10 mm, D_4^{141} 1·3395, n_D^{141} 1·46458. All endeavours to produce a substance, $\underset{\mathrm{CH_2-CO}}{\mathrm{OH\cdot CH\cdot CCl_2}}{>}\mathrm{O}$, by elimination of hydrogen chloride from the tri-chlorohydroxybutyric acid were fruitless.

The method described by Kötz (A., 1907, i, 707) for the preparation of $\gamma\gamma\gamma$-trichlorocrotonic acid is found to yield the above trichloro-hydroxybutyric acid, and the m. p. given for the substance (*loc. cit.*) agrees with that of this acid. It is now found that the elements of water can be eliminated from trichlorohydroxybutyric acid by heating with acetic anhydride and sodium acetate; the resultant $\gamma\gamma\gamma$-*trichloro-crotonic acid* forms needles, m. p. 113—114°, b. p. 143—146°/18 mm.; it immediately reduces potassium permanganate in the cold, and is rapidly decomposed by hot water with formation of hydrochloric acid. The *potassium* and *silver* salts were prepared, the latter of which when heated in benzene on the water-bath eliminates silver chloride with the formation of a mixture of substances mainly complex, but possibly containing a little of the *lactone*, $\underset{\mathrm{CH-CO}}{\mathrm{CH-CCl_2}}{>}\mathrm{O}$. The acid forms an oily *methyl* ester, b. p. 85·4°/12 mm., D_4^{211} 1·3968, n_D^{211} 1·48075, and an oily *ethyl* ester, b. p. 100·5°/13 mm., D_4^{143} 1·3375, n_D^{143} 1·48693.

From the above results it follows that the group $-CCl_3$ exerts no special spectrochemical influence.   D. F. T.

The Constitution of the Chlorides of 1 : 2- and 1 : 3-Di-carboxylic Acids. KARL VON AUWERS and M. SCHMIDT (*Ber.*, 1913, 46, 457—487).—The consideration of the spectrochemical effect of chlorine in organic substances (von Auwers, A., 1912, ii, 1015) is extended to the question of the structure of such acid dichlorides

as succinyl and phthalyl chlorides (compare Scheiber, A., 1912, i, 559; Scheiber and Knothe, A., 1912, i, 701; Bredt, A., 1912, i, 411; Ott, A., 1912, i, 828). The decision of Bruhl as to the symmetrical structure of phthalyl chloride (*Ber.*, 1907, **40**, 884, 896) is based on too little experimental evidence to be entirely satisfactory; an investigation of the specific exaltations of the refractivity and dispersive power of various acid chlorides nevertheless indicates the correctness of this view.

A comparison of the chlorides and ethyl esters of crotonic, benzoic, and cinnamic acid shows that the exaltations in specific refractivity stand in the order acid > chloride > ester, whilst for the dispersion the exaltation is least for the ester, the free acid and the chloride being approximately equal. Phthalyl chloride shows no exceptional exaltation when compared with ethyl phthalate, the values in fact being in good agreement with those for the corresponding derivatives of benzoic acid; the results, however, when compared with those calculated for the unsymmetrical formula $C_6H_4{<}^{COCl_2}_{CO-}{>}O$ would indicate an improbably large exaltation.

The ethyl ester and chloride of fumaric acid exhibit exaltations approximately equal to those of the corresponding phthalic acid compounds; *iso*phthalic ester and chloride have exaltations appreciably higher, but this is probably to be attributed to the effects of structure isomerism. Maleyl chloride could not be obtained sufficiently pure for spectrochemical investigation.

In order to throw further light on this question, most of the chlorides of the oxalic series of acids were examined from oxalic to sebacic acid, and no exaltation was observed except a trace in the case of oxalyl chloride which may be attributed to the –CO·CO– group. Succinyl and glutaryl chloride must therefore be entirely of the symmetrical dichloride structure.

In the absence of pure, simple derivatives of the dichlorolactone molecule $^{CH·CCl_2}_{CH—CO}{>}O$, αδ dichloro-γ valerolactone,

$$^{CHCl·CO——}_{CH_2·CH(CH_2Cl)}{>}O$$
(Leuchs and Gius, A., 1912, i, 603, 604), was investigated and compared with the lactones of δ-methoxy- and δ-ethoxy-γ hydroxyvaleric acids, and with methyl αβ butyleneoxide-δ-carboxylate. All were found to be optically normal. It is therefore probable that the hypothetical dichlorolactonic structure for succinyl and phthalyl chlorides would also be optically normal.

d-*cis*-Camphoryl, *l*-*trans*-camphoryl, *d*-chlorocamphoryl, and dehydrocamphoryl chlorides from their spectrochemical behaviour are probably all normal acid chlorides. The first and third named certainly exhibit a certain negative exaltation, but as this is also to be observed with the corresponding esters it probably arises from the *gem*-dimethyl groups (see this vol., ii, 261).

A comparison of the chlorides and esters of chlorofumaric and fumaric acids shows a similar exaltation in the chloride and ester

of each acid, thus indicating the normal symmetrical structure of the chlorides. With chloromaleyl chloride, however, the molecular refraction is below that of the isomeric chlorofumaryl chloride, and is in agreement with that calculated on theoretical grounds for the structure

$$\begin{matrix} CH\cdot CCl_2 \\ \| \\ CCl-CO \end{matrix}\!>\!O$$; the lactonic formula is also favoured by a consideration

of the molecular volume (Ott, *loc. cit.*). The structure of phthalyl chloride, on the other hand, is almost certainly the symmetrical one, as is indicated by recent chemical and physicochemical investigations (Scheiber, *loc. cit.*; Ott, *loc. cit.*) and by the present confirmation of Brühl's results. The constitution of the chlorides of the isomeric camphoric acids, chlorocamphoric acid, and dehydrocamphoric acid is also decided in favour of the symmetrical acid chloride form (compare Scheiber and Knothe, *loc. cit.*).

Succinyl chloride gave curiously variable results for density, refraction, and dispersion, probably due to some difficultly removable impurity ; a specimen regarded as pure, indicated a true acid chloride structure, as already suggested by Ott.

The following substances were examined, but only the refraction for sodium light is quoted below; the original paper gives the values for the α-, β-, and γ-lines also.

Acetyl chloride, b. p. 51—52°, $D_4^{20\cdot6}$ 1·1039, $n_D^{20\cdot8}$ 1·38831 ; *isovaleryl* chloride, b. p. 114·5—115·5°/771 mm., $D_4^{21\cdot3}$ 0·9854, $n_D^{21\cdot3}$ 1·41361 ; crotonyl chloride, b. p. 117—120°/754 mm., $D_4^{17\cdot4}$ 1·0822, $n_D^{17\cdot9}$ 1·46001 ; methyl αβ-butyleneoxide-δ-carboxylate [γδ-oxidovalerate],
$$\begin{matrix} CH_2 \\ O \end{matrix}\!>\!CH\cdot CH_2\cdot CH_2\cdot CO_2Me,$$

F. T.

Preparation of Terpenylic and Terebic Acids　Rɛ́né Locquin

(*Bull. Soc. chim.*, 1913, [iv], **13**, 166—169).—Tiemann and his collaborators (A., 1895, i, 548 ; 1896, i, 385 ; 1897, i, 84) have suggested that methoethylheptanonolide yields terpenylic acid on oxidation by chromic acid, and terebic acid when oxidised by nitric acid, and may be used as a source of these two acids　The author finds that on oxidation by nitric acid, terpenylic acid is the chief product (58·2% of the theoretical), the yield of terebic acid (18 6% of the theoretical) being small.　The preparation and separation of the two acids are described.　　　　T. A. H.

Attempts to Synthesise Monosubstituted Paraconic Acids.

Philippe Barbier and Réné Locquin (*Bull. Soc. chim.*, 1913, [iv], **13**, 161—166.　Compare A., 1911, i, 708) —The only method hitherto available for the preparation of these acids is that of Fittig (A., 1890, i, 583), which gives poor yields when aliphatic aldehydes are used. The authors have modified Reformatsky's reaction for the production of β-hydroxy-acids (A., 1896, i, 128) with a view to preparing monosubstituted paraconic acids by this means, but the yields are poor, only 7% of the theoretical yield of *iso*propylparaconic acid being obtained, and 12% of the calculated yield of hexylparaconic acid.　The latter acid had m. p. 79—80°, which is 10° below that recorded by Schneegans.
　　　　T. A. H.

Preparation of Strontium Cholate.　Knoll & Co. (D.R.-P.

254530).—*Strontium cholate*, $(C_{24}H_{89}O_5)_2Sr,10H_2O$, colourless, hair-like tufts is readily obtained when an alcoholic solution of cholic acid is heated with an aqueous solution (or suspension) of strontium hydroxide ; it has an important therapeutic action.　　　　F. M. G. M.

Oxidation of Aldehydes by an Aqueous Solution of Bromine.

Ernest Anderson (*Amer. Chem. J.*, 1913, **49**, 179—184).—It is usually supposed that the method used for converting aldoses into the corresponding acids by oxidation with aqueous solution of bromine is not applicable to the ordinary aldehydes.　In order to test this question, several aldehydes have been subjected to the action of bromine, and the oxidation products isolated.　The results show that whilst benzaldehyde, acetaldehyde, paraldehyde, and formic acid give good yields of the corresponding acids, namely, benzoic, acetic, and carbonic, formaldehyde and aldol are oxidised to only a small extent, and salicylaldehyde and chloral not at all.

Acetaldehyde was found to give 71% of the theoretical yield of acetic acid ; benzaldehyde, 80% of benzoic acid ; paracetaldehyde, 86% of acetic acid ; and formic acid, 80% of carbonic acid.　　　　E. G.

Glyoxal. CARL D. HARRIES (*Ber.*, 1913, **46**, 294--296. Compare A., 1907, i, 183)—Polymerisation of glyoxal is accelerated by the presence of moisture. When technical glyoxal which has been dried over phosphoric oxide at 95° is distilled alone, the unimolecular compound is obtained. It is claimed that Meisenheimer's depolymerisation of methylglyoxal (A., 1912, i, 831) was foreshadowed in the above-mentioned paper.   J. C. W.

Catalytic Preparation of Ketones. JEAN B. SENDERENS (*Ann. Chim. Phys.*, 1913, [viii], **28**, 243—344).—A résumé of work already published (A., 1909, i, 286, 627; 1910, i, 11, 179, 489; 1911, i, 134, 302; 1912, i, 537).   H. W.

The Synthesis of Sugars by means of Radioactive Emanations. JULIUS STOKLASA, JOHANN ŠEBOR, and WENZEL ZDOBNICKÝ (*Compt. rend.*, 1913, **156**, 646—648. Compare A., 1911, i, 178, 769).—As with ultra-violet rays, so under the influence of radium emanation hydrogen and carbon dioxide react in the presence of potassium hydrogen carbonate, giving formaldehyde, which in the presence of potassium hydroxide polymerises and gives reducing sugars. No formates could be detected during the reaction. The sugars formed are a mixture of hexoses giving phenylosazones, separable into two fractions, one, m. p. 198—199°, and the other, m. p. 178°. Unlike the sugars obtained in the photochemical synthesis under the influence of ultra-violet rays (compare A., 1912, i, 606), these sugars are optically active and have $[\alpha]_D$ +17·58°. By distillation with hydrochloric acid indications of the presence of a pentose were obtained.
                                                W. G.

Preparation of δ-Dimethylamino-Δ^a-*iso*amylene and δ-Dimethylamino-Δ^a-butylene. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254529. Compare A., 1912, i, 742, 781; and Euler, A., 1897, i, 585).—δ-*Dimethylamino-Δ^a-isoamylene*,
                $CH_2{:}CH{\cdot}CHMe{\cdot}CH_2{\cdot}NMe_2$,
a colourless liquid, b. p. 113—116°, and identical with the so-called "β-methyldimethylpyrrolidine" (Euler, *loc. cit.*), can be prepared by heating γ-hydroxy-β-methylbutyldimethylamine with concentrated sulphuric acid (3 parts) during three to four hours at 100°, or with 50% sulphuric acid (5—10 parts) during ten hours at 150—160°.
δ-*Dimethylamino-Δ^a-butylene*, $CH_2{:}CH{\cdot}CH_2{\cdot}CH_2{\cdot}NMe_2$, a colourless liquid, b. p. 94—96°, is obtained in a similar manner from γ-hydroxybutyldimethylamine with 20—30% sulphuric acid (5 parts) at 200° during ten hours.

These compounds have an odour of goniine, and find employment in the preparation of isoprene and erythene.   F. M. G. M.

Preparation of δ-Dimethylamino-γ-dimethylbutan-β-ol. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254713).—When methyl tetramethyldiamino*iso*propyl ketone (following abstract) is boiled during one hour with 20% sulphuric acid (4—6 parts), it furnishes *dimethylamino-β-acetylallylene*, $CH_2{:}CAc{\cdot}CH_2{\cdot}NMe_2$, which

on reduction gives rise to δ-dimethylamino-γ methylbutan-β-ol (A., 1911, i, 598), a colourless oil, b. p. 67—69°/17 mm.   F. M. G. M.

Preparation of Amino- and Diamino-ketones of the Aliphatic Series. FARBENFABRIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 254714. Compare A., 1911, i, 598, and preceding abstract). —When dimethylaminomethyl alcohol, $OH \cdot CH_2 \cdot NMe_2$, or tetramethyldiaminomethane, $Me_2N \cdot CH_2 \cdot NMe_2$, are condensed with acetone (or its homologues), the following reactions take place (R = hydrogen or alkyl).

1. $CH_3 \cdot CO \cdot CH_2R + OH \cdot CH_2 \cdot NMe_2 =$
$$CH_3 \cdot CO \cdot CHR \cdot CH_2 \cdot NMe_2 + H_2O.$$

2. $CH_3 \cdot CO \cdot CH_2R + NMe_2 \cdot CH_2 \cdot NMe_2 =$
$$NHMe_2 + CH_3 \cdot CO \cdot CHR \cdot CH_2 \cdot NMe_2.$$
The following compounds are described : dimethyl-β-acetylpropyl-amine (*loc. cit.*), b. p. 51—51·5°/13 mm.

ββ-Acetylmethyltrimethylenetetramethyldiamine [*methyl tetramethyldiaminotert.-butyl ketone*], $CH_3 \cdot CO \cdot CMe(CH_2 \cdot NMe_2)_2$, a colourless, viscous oil, b. p. 110—112°/18 mm., from methyl ethyl ketone and dimethylaminomethyl alcohol.

β-Acetylethyldimethylamine [*methyl dimethylaminoethyl ketone*],
$$CH_3 \cdot CO \cdot CH_2 \cdot CH_2 \cdot NMe_2,$$
a colourless oil with a strong ammoniacal odour, b. p. 57—58°/18 mm. ; and *β-acetyltrimethylenetetramethyldiamine* [*methyl tetramethyldiamino-*iso*propyl ketone*], $CH_3 \cdot CO \cdot CH(CH_2 \cdot NMe_2)_2$, a colourless, odourless, viscous oil, b p. 96—98°/16 mm.
These compounds are employed in the preparation of erythrene and isoprene.   F. M. G. M.

Preparation of Urethanes of Tertiary Alcohols. EMANUEL MERCK (D.R.-P. 254472. Compare this vol., i, 5).—It is found that the halogen formyl esters described previously can be readily converted by the action of ammonia or substituted ammonias into urethanes of tertiary alcohols :
$$OR \cdot CO \cdot Cl + 2NHR_1R_2 \longrightarrow OR \cdot CO \cdot NR_1R_2 + NHR_1R_2, HCl,$$
where RO is a tertiary alcoholic group, and R_1 and R_2 hydrogen, alkyl or aryl groups.

Dimethylethylcarbinyl chloro-formate with alcoholic ammonia furnishes a *urethane*, colourless needles, m. p. 85—87° ; an *ethyl urethane*, a colourless oil, b. p. 89°/13 mm., and 86°/11 mm. ; a *phenyl-urethane*, colourless crystals, m. p. 44—47°, b. p. 146°/9 mm. ; a *methyl-phenylurethane*, a colourless oil, b. p. 133°/13 mm., and with *p*-pheno-tidine a p-*ethoxyphenylurethane*, colourless needles, m. p. 88—90°, whilst methyldiethylcarbinol gives rise to a *urethane*, colourless needles, m. p. 61°, and a *phenylurethane*.   F. M. G. M.

Behaviour of Formamide Under the Influence of the Silent Electric Discharge. The Question of Nitrogen Assimilation. WALTHER LÖB (*Ber.*, 1913, **46**, 684—697).—In the course of some experiments on the influence of the silent electric discharge on various combinations of moist carbon dioxide, carbon monoxide,

alcohol and ammonia, with or without oxygen or air, the only com
pound obtained which could be regarded as of interest to the problem
of nitrogen assimilation was hexamethylenetetramine (A , 1909, i, 769).
Further investigations on the behaviour of this compound towards
oxidising and reducing agents, and towards living yeast, showed that
it had no relation to the amino-acids, and, therefore, throws no light
on the general question. The discovery of Losanitsch and Jovitschitsch
(A., 1897, i, 179) that ammonia and carbon monoxide produce form-
amide led the author to regard this compound as an intermediate stage,
and to try the effect of the silent discharge on the dry substance and
on an aqueous solution, both boiling under reduced pressure.   In the
former case, oxamide was deposited on the sides of the discharge tube,
and in the latter, as would be expected, ammonium oxamate. Some
reduction was therefore necessary in order to arrive at glycine.
Previous experience had shown that water itself is a reducing agent
under these conditions (A., 1906, ii, 324), whilst the reaction
$CO + H_2O = CO_2 + H_2$ had also to be considered. The resolution of
some formamide into carbon monoxide and ammonia was to be
expected, and, indeed, an examination of the gases liberated during the
experiment proved the presence of these substances.   The existence
of glycine in the product, after the removal of ammonia, was unques-
tionably demonstrated by the formaldehyde test of Sörensen, the
"deaminising" method of van Slyke, the reaction with triketo-
hydrindene hydrate, and the formation of the naphthalenesulphonyl
compound (E. Fischer and Bergell, A., 1903, i, 24).

The presence of glycine could also be observed on repeating the
experiment with moist carbon monoxide and ammonia. The formation
of glycine from carbon dioxide (which breaks down into carbon
monoxide under the influence of the silent discharge), ammonia, and
water is therefore a process of reduction, and the oxidation of glycine
should lead to these or intermediate products. Halsey has shown
that the products of the action of permanganate do, indeed, include
formamide and oxamic acid (A , 1898, ii, 529).

The reactions may be formulated thus:
$$\text{(I)} \quad 2CO_2 + 2NH_3 + H_2O \longrightarrow 2H \cdot CO \cdot NH_2 + H_2O + O_2.$$
$$\text{(II)} \quad 2H \cdot CO \cdot NH_2 + H_2O \longrightarrow NH_2 \cdot CO \cdot COONH_4 + H_2.$$
$$\downarrow$$
$$NH_2 \cdot CH_2 \cdot COONH_4 + O.$$
Reference must be made to the original paper for the experimental
details, but it may be said that the amount of oxamide accumulated
during twenty hours from 20 grams of dry formamide, boiling at
110°/15 mm., was about 0 05—0·08 gram, whilst about 0·01 gram of
ammonium oxamate was obtained from a 5 –10% solution during the
same time, the glycine present being comparable with a 0 01% solution.
                                                                J. C. W.

The Diamide of Sulphoisobutyric Acid. JACOB MOLL VAN
CHARANTE (Rec. trav. chim., 1913, 32, 90—96. Compare A., 1905, i,
16).—Sulphoisobutyrodiamide, $NH_2 \cdot SO_2 \cdot CMe_2 \cdot CO \cdot NH_2$, was obtained
by passing ammonia into a cold methyl-alcoholic solution of methyl

chlorosulpho*iso*butyrate. It decomposed without melting at about 340°. At 17°, one part of diamide dissolved in 201·8 parts of water, whilst at 100° the solubility was one part in 24·9. It was insoluble in the other usual solvents. Attempts to condense it with carbonyl chloride, in the presence or absence of a catalyst, were unsuccessful. Similarly, oxalyl chloride, alone or in benzene solution, was without action on it.

To determine whether it was possible to cause a sulphonamide to react with oxalyl chloride, a solution of benzenesulphonamide and oxalyl chloride in benzene was boiled during two and a-half days. Hydrogen chloride was slowly evolved, and *diphenylsulphonoxamide*, $C_2O_2(NH·SO_2Ph)_2$, formed. It had m. p. 256° (corr., slight decomp.).

H. W.

Extraction of Glutamic Acid Hydrochloride and Betaine Hydrochloride from Molasses Residue. HUGO STOLTZENBERG (*Ber.*, 1913, **46**, 557—566. Compare A., 1912, i, 680).—Molasses residue is mixed with hydrochloric acid and subsequently saturated with hydrogen chloride. The crude hydrochlorides which are precipitated are treated with alcohol and hydrogen chloride, whereby glutamic acid hydrochloride is converted into the readily soluble ester hydrochloride. The solution of the latter is concentrated to a syrup, the residue boiled with water, the solution filtered from humin, decolorised, and concentrated until crystallisation begins, when it is again saturated with hydrogen chloride, whereby glutamic acid hydrochloride is precipitated. This has m. p. 213° when rapidly heated, and is shown to be partly racemised, the highest observed value for $[\alpha]_D^{15}$ being $+26·15°$ in 10% hydrochloric acid solution, whereas Siegfried and Schutt (A., 1912, i, 952) observed $+34·89°$. Purification by transformation into the barium salt and subsequent reprecipitation of the hydrochloride effected no improvement. The filtrates obtained after removal of glutamic acid hydrochloride deposited, on evaporation, betaine hydrochloride, and contained also a strongly acid *substance*, which could not be obtained in the crystalline state.

The remainder of the paper consists of a reply to the criticisms brought by Ehrlich (A., 1912, i, 835) against the previous work of the author (*loc. cit.*). Stoltzenberg's process of isolating betaine hydrochloride from molasses differs essentially from that of Ehrlich (1904, D.R.-P. 157173), in that hydrochloric acid and alcohol are employed in the given order in the former process, in the inverse order in the latter. In the second method, the chemical nature of the residue is not affected by agitation with alcohol, and the hydrogen chloride is only used to precipitate the hygroscopic betaine. In the first method, however, the composition of the residue itself is greatly altered by the action of the hydrogen chloride. Ehrlich's statement that the alcohol consumption is less in his process than in that of the author is incorrect.

The paper concludes with a critical survey of the historical development of the subject as described by Ehrlich. H. W.

Action of Sodium Hypobromite on Semicarbazide. ROBERT STOLLÉ (*Ber.*, 1913, **46**, 260. Compare Linch, T., 1912, **101**, 1755).

—The product of the action of sodium hypobromite on semicarbazide is hydrazodicarbonamide, and not *p*-urazine as described by Linch. The compound obtained on oxidation with chromic acid is therefore azodicarbonamide (Thiele, A., 1892, 1295 and 1430), and not a stable tetrazine.   J. C. W.

Salt- and Complex Salt-Formation with Amino- and Hydroxy-acetohydroxamic Acids. HEINRICH LEY and F. MANNCHEN (*Ber.*, 1913, **46**, 751—758).—On account of the similarity in structure between the carboxylic and hydroxamic acids, the authors have investigated certain derivatives of the latter in which the formation of complex salts was to be expected. It is found that internally complex salts are obtainable from amino- and hydroxy-hydroxamic acids somewhat analogous to those obtained from the simple amino-acids. To the normal copper salts is attributed the

structure $R{\cdot}C{<}^{NO}_{O}{>}Cu$; acid salts could be obtained only from sub-

stituted hydroxamic acids, and the constitution suggested is

$$CH_2{<}^{NH_2}_{C(:NOH){\cdot}O}{>}M{<}^{NH_2}_{O{\cdot}C(:NOH)}{>}CH_2$$
(compare Ley, A., 1909, i, 138), where M represents a bivalent metal atom. Complex salts containing a bivalent metal together with an alkali metal could be obtained both from the unsubstituted and substituted acids ; the heavy metal is present as part of a complex ion, but from the colour of the salts of the amino- and hydroxy-substituted acids the conclusion is drawn that this atom is also linked with the anion complex by supplementary partial valencies.

Aminoacetohydroxamic acid, $NH_2{\cdot}CH_2{\cdot}C(OH){:}N{\cdot}OH$, was obtained by the interaction of equimolecular quantities of hydroxylamine, ethyl aminoacetate, and sodium ethoxide in alcoholic solution ; it was precipitated as the copper salt and recovered by the action of hydrogen sulphide ; it is a colourless, crystalline solid, m. p. 107° (approx.) ; normal *copper* salt, green, amorphous powder, obtained by mixing aqueous solutions of the acid and copper acetate ; *acid copper* salt, obtained by adding copper acetate to a solution of the *sodium* salt, separates in violet crystals ; *acid nickel* salt, prepared by the addition of dilute sodium hydroxide solution to a solution of nickel acetate with a bimolecular quantity of the acid, forms deep red crystals ; the complex *sodium nickel* salt, $(C_2H_3O_2N_2)_2NiNaH,H_2O$, yellowish-red, rhombic tablets, was obtained by treating a solution of the sodium salt with nickel acetate and sodium hydroxide.

Anilinoacetohydroxamic acid, $NHPh{\cdot}CH_2{\cdot}C(OH){:}N{\cdot}OH$, colourless needles, m. p. 126° (decomp.), separates in the form of the *sodium* salt when ethyl anilinoacetate is treated in alcoholic solution with an equimolecular quantity of hydroxylamine ; *copper* salt, green, amorphous solid.

Phenylglycollohydroxamic acid, $OH{\cdot}CHPh{\cdot}C(OH){:}N{\cdot}OH$, colourless, rhombic leaflets, m. p. 132°, was prepared in a similar manner to the last ; *sodium* salt, needles ; the green *copper* salt, like that of the last acid, gives a violet solution in aqueous sodium hydroxide ; the *nickel sodium* salt could be obtained only as a reddish-yellow solution.

The free acid soon decomposes in solution with the formation of benzaldehyde.

Phenoxyacetohydroxamic acid, $OPh \cdot CH_2 \cdot C(OH){:}N \cdot OH$, prepared in an analogous manner from ethyl phenoxyacetate, forms colourless leaves, m. p. 114°; the addition of copper acetate and sodium hydroxide solution to the solution of the *sodium* salt causes the formation of the crystalline, bluish-violet *copper sodium* salt,

$$(C_8H_7O_3N)_2CuNa_2, 2H_2O,$$
which is converted by water into the green *copper* salt.

The interaction of equimolecular quantities of hydroxylamine, ethyl lactate, and sodium ethoxide in alcoholic solution produces unstable *sodium lactohydroxamate*, $CH_3 \cdot CH(OH) \cdot C(ONa){:}NOH$.

An aqueous solution of acetohydroxamic acid (Miolati, A., 1892, 699) when treated with copper acetate and sodium hydroxide, after some days, deposits blue crystals of a complex *copper sodium* salt,

$$(C_2H_3O_2N)_2CuNa_2, 7H_2O,$$
which is converted by water into the ordinary green copper salt.

New Method of Preparing Nitriles of the Aliphatic Series. ALEXANDER E. ARBUZOV (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 74—79). —Catalytic decomposition of the hydrazones of aliphatic aldehydes in presence of cuprous chloride, platinous chloride, or zinc chloride always yields nitriles to some extent, although the yield varies considerably. In general, hydrazones containing small radicles give very small proportions of nitriles, the decomposition then yielding principally substituted indoles and other compounds (see this vol., i, 388). On the other hand, hydrazones containing large radicles, such as *iso*valeraldehydephenylhydrazone, undergo nitrilic decomposition almost exclusively : $C_5H_{10}N \cdot NHPh = NH_2Ph + C_5H_9N$.

*iso*Valeronitrile, thus obtained in 56% yield, is a colourless, mobile liquid, b. p. 128·5°, or 52·5—53°/50 mm., D_0^0 0·7884, D_0^{20} 0·8054 (compare Erlenmeyer, *Annalen*, 1871, **160**, 266).

*iso*Butyronitrile is similarly obtained from *iso*butaldehydephenylhydrazone in 37% yield, and *n*-heptonitrile, b. p. 183·5°, D_0^{20} 0 8107 (compare Henry, A., 1905, i, 561), from *n*-heptaldehydephenylhydrazone.

<div align="right">T. H. P.</div>

Chromates and Mercuric Cyanide. DANIEL STRÖMHOLM (*Zeitsch. anorg. Chem.*, 1913, **80**, 155—160. Compare A., 1912, ii, 648).—The following compounds have been obtained :

$$(NH_4)_6Cr_2O_7Cl_4, 6Hg(CN)_2, 4H_2O,$$
long, reddish-yellow crystals, with only a narrow range of stability ; $2K_2CrO_4, 3Hg(CN)_2, 2H_2O$. A chloride-chromate salt has not been obtained in the case of potassium.

<div align="right">C. H. D.</div>

Potassium β-Ferricyanide. HORACE L. WELLS (*Amer. Chem. J.*, 1913, **49**, 205—206).—Hauser and Biesalski (this vol., i, 26) have stated that the potassium β-ferricyanide described by Locke and Edwards (A., 1899, i, 407) is merely the ordinary salt, contaminated with colloidal Prussian-blue. It is now shown that this view is incorrect, and that Hauser and Biesalski have overlooked the fact that the

β ferricyanide does not yield a precipitate with bismuth nitrate, and is thus readily distinguished from the ordinary salt.   E. G.

Crystalline Form of Two Scandium Platinocyanides. PETR N. TSCHIRVINSKI (*Zeitsch. Kryst. Min.*, 1913, **52**, 44—47).—The crystalline form, as observed under the microscope, is described for the yellow salt, $Sc_2[Pt(CN)_4]_3,18H_2O$, and for the red salt,
$$Sc_2[Pt(CN)_4]_3.21H_2O.$$
New observations are also given for the yttrium salt,
$$Y_2[Pt(CN)_4]_3,21H_2O.$$ L. J. S.
Magnesium Methyl Iodide. PIERRE JOLIBOIS (*Compt. rend.*, 1913, **156**, 712—714. Compare A., 1912, i, 675, 753).—The action of methyl iodide on magnesium in dry ether is a simple one, there being practically no secondary reaction under any conditions. The magnesium methyl iodide, so obtained, when heated in a vacuum, first loses its ether of constitution at 130°, and at 240° methane is evolved, according to the equation : $2MgMe_2,MgI_2 = 3CH_4 + Mg_2C,2MgI_2$.

By raising the temperature to 600° no more gas is evolved. The residue is a voluminous, yellow mass, from which only a definite portion of the iodine can be extracted in the form of magnesium iodide by dry ether, leaving a *compound*, having the definite composition Mg_2C,MgI_2, which is violently decomposed by water with development of light and heat, and, on controlled decomposition by moist ether, yields practically pure methane.   W. O.

The Catalytic Hydrogenation of Camphorone. Some New *cyclo*Pentane **Hydrocarbons.** MARCEL GODCHOT and FÉLIX TABOURY (*Compt. rend.*, 1913, **156**, 470—473).—Camphorone on hydrogenation in the presence of reduced nickel at 130° yields dihydrocamphorone (compare Semmler, A., 1904, i, 260). If the reduction is carried out at 280°, the product obtained is 1-*methyl*-3-*iso*-*propyl*cyclopentane, $C_5H_8MePr^\beta$, a liquid with a terpene-like odour, b. p. 132—134°, D^{19} 0·773, n_D^{19} 1·4250. The same compound is obtained by dehydrating 1-methyl-3-*iso*propyl*cyclo*pentane-2-ol with zinc chloride, which furnishes a mixture of two isomeric unsaturated hydrocarbons, b. p. 143—145°, D^{18} 0·786, n_D^{18} 1·4465, non-separable, but which on hydrogenation at 170° are converted into the pentane hydrocarbon.

Dihydrocamphorone reacts with magnesium methyl iodide, giving a mixture of 1 : 2-*dimethyl*-3-isopropyl-Δ^1- and -Δ^2-*cyclopentenes*, b. p. 150—155°, D^{17} 0·812, n_D^{17} 1·4500, which on hydrogenation at 180° are transformed into 1 : 2-*dimethyl*-3-isopropyl*cyclo*pentane, b. p. 146—148°, D^{16} 0·786, n_D^{16} 1·4337. Similarly by using magnesium *iso*propyl iodide a mixture of 1-*dimethyl*-2 : 3-*diisopropyl*-Δ^1- and -Δ^2-*cyclopentene*, b. p. 160—168°, D^{16} 0·812, n_D^{18} 1·4509, is obtained, yielding on hydrogenation at 180°, 1-*methyl*-2 : 3-*diisopropyl*cyclopentane, b. p. 150—152°, D^{17} 0·781, n_D^{17} 1·4318.   W. G.

The *cyclo*Octane **Series. VI.** *cyclo*Octatetraene. RICHARD WILLSTÄTTER and MICHAEL HEIDELBERGER (*Ber.*, 1913, **46**, 517—527. Compare Willstätter and Waser, A., 1912, i, 17).—The previous

observations with *cyclo*octatetraene have been repeated and extended. The quaternary ammonium base is now distilled in a still lower vacuum and at a correspondingly lower temperature (30—45°). On cooling, the hydrocarbon solidifies to a pale yellow, crystalline mass, m. p. − 27°. It forms an additive compound with bromine, taking up two atoms only. The *dibromide*, $C_8H_8Br_2$, crystallises in lustrous, snow-white needles, m. p. 70—71·5° (corr.). It decolorises permanganate instantaneously and tends to take up more bromine, but hydrogen bromide is then eliminated, and a *substance*, $C_8H_7Br_3$, m. p. 53—55°, is obtained instead of the tetrabromide.

The tetraene reacts immediately with chlorine, and hydrogen chloride is eliminated ; an oily *chloride* is obtained, and can be separated into two fractions, both of which have the composition $C_8H_7Cl_3$.

With hydrogen bromide in acetic acid solution the tetraene forms a *hydrobromide*, C_8H_9Br, which is an almost colourless oil with a sweet odour, b. p. 85—87°/12·5 mm. It slowly decomposes in presence of oxygen, and gives an orange coloration with concentrated sulphuric acid.

The molecular refraction of *cyclo*octatetraene shows little or no exaltation. Similarly, the molecular dispersion $(\beta—\alpha)$ shows no marked exaltation, although in consequence of the greater dispersion in the ultra-violet the molecular dispersion, $M_\gamma—M_\alpha$, shows a larger exaltation.

The tetraene behaves, like benzene, optically normal in regions where it is free from absorption ; the dispersion is, however, abnormal in the region where selective absorption takes place.

Such selective exaltation of the molecular dispersion is even more marked in the case of the yellow fulvenes ; data are quoted for methylethylfulvene and dimethylfulvene, as well as *cyclo*octatriene.

When *cyclo*octatetraene is hydrogenated by the platinum method the yellow colour disappears after the addition of 1·5 molecules of hydrogen. The first three molecules appeared to be absorbed in approximately equal times and the fourth more slowly, the actual figures being 35, 40, 40, and 95 minutes respectively.

Methylethylfulvene does not lose the yellow colour until reduction is nearly complete. The three molecules of hydrogen were absorbed in 7, 7, and 10 minutes.

The product, *sec.-butyl*cyclopentane, is a mobile liquid, with an odour like limonene, b. p. 152—154°/725 mm., D_4^0 0·810.

The *cyclo*octane formed even from pure *cyclo*octatetraene is not pure, and probably contains an isomeride.

Pure *cyclo*octatetraene may be kept for several months without decomposition. E. F. A.

[Preparation of *cyclo*Hexene.] BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 254473. Compare A., 1899, i, 22 ; 1902, i, 2, and T., 1898, 73, 941).—When the vapour of chloro*cyclo*hexane at 350—450°/15—20 mm. is conducted over a catalytic agent (such as barium chloride, aluminium oxide, or nickel chloride), it gives rise to. *cyclo*hexene. F. M. G. M.

Rational Preparation of Some Benzene Homologues.   II.
FRANZ KUNCKELL and GEORG ULEX (*J. pr. Chem.*, 1913, [ii], **87**,
227—236).—A continuation of previous work (this vol., i, 29) on the
preparation of benzene homologues by the interaction of alkyl esters of
chloro-formic acid with aromatic hydrocarbons in the presence of
aluminium chloride.

Methyl chloro-formate reacts with benzene to form toluene and
m-xylene; with toluene it yields *p*-xylene and ψ-cumene.

The interaction of ethyl chloro-formate with benzene and toluene
yields respectively *p*-diethylbenzene and 1-*methyl*-3 : 4-*diethylbenzene*,
b. p. 200—203°, the constitution of which has been established by its
oxidation to 4-methylphthalic acid.

m-Xylene reacts with ethyl chloro-formate, yielding 1 : 3-*dimethyl*-
5-*ethylbenzene*, b. p. 182—188°, and with *p*-xylene to form 1 : 4-*dimethyl*-
2-*ethylbenzene*, b. p. 183—185°.

The interaction of cumene with methyl and ethyl carbonates yields
dimethylisopropylbenzene, b. p. 195—210°, and *diethylisopropylbenzene*,
b. p. 250—256° respectively.

The addition of *iso*butyl chloro-formate to a mixture of aluminium
chloride and benzene gives rise to *tert.*-butylbenzene, whilst the
addition of aluminium chloride to a mixture of the ester with
benzene yields *di*-(tert. ?)-*butylbenzene*, b. p. 225—235°, and *tri*-(tert. ?)-
butylbenzene.

The preparation of a *p*(?)-methylbutylbenzene, b. p. 190—195°, and a
methyldibutylbenzene, b. p. 241—247°, from toluene and *iso*butyl chloro-
formate, and p-*methylamylbenzene*, b. p. 205—210°, from amyl chloro-
formate and toluene is also described.   F. B.

Chemical Action of Light.   XXV.   Autoxidations.   III.
GIACOMO L. CIAMICIAN and PAUL SILBER (*Ber.*, 1913, **46**, 417—422*).—
A continuation of the investigation of the autoxidation of aromatic
hydrocarbons (A., 1912, i, 174, 645)   The results are in accordance
with those of Suida (A., 1912, i, 957), but as the present authors gave
prolonged exposure to light and investigated only the final products,
indications of peroxides were but rarely observed.

Benzene in contact with water and oxygen is completely unaltered
after several months' exposure to sunlight (compare Suida, *loc. cit.*).

Ethylbenzene under similar conditions gives a yellow aqueous layer,
and after neutralisation with sodium carbonate, ether extracts aceto-
phenone with some unchanged ethylbenzene ; the former was charac-
terised by its semicarbazone; this, it was observed, separates from
methyl alcohol with one molecule of alcohol of crystallisation, which is
lost on drying over sulphuric acid.   The alkaline solution, which
had been extracted with ether, was found to contain formic and benzoic
acids.

Mesitylene, when treated similarly, gave a strongly acidic mixture,
which after neutralisation yielded an ethereal extract containing
mainly unchanged hydrocarbon, together with a small quantity of a
non-volatile *substance* and a trace of an aldehyde.   The aqueous liquid
on acidification gave formic acid, mesitylenic acid, a substance probably

a polycarboxylic acid which sublimed near 300°, and some resinous matter.

The oxidation product of ψ-cumene contained as its neutral constituents only unchanged hydrocarbon and a trace of an aldehydic substance ; the acidic constituents comprised formic acid, together with 3 : 4-dimethylbenzoic acid, 2 : 4-dimethylbenzoic acid, and a difficultly volatile, crystalline *substance* ; the presence of 2 : 5-dimethylbenzoic acid could not be detected.

Indene was practically completely changed, and the reaction mixture slowly gave the reaction for a peroxide. A relatively large amount of resinous matter was produced which was partly soluble in ether, the soluble portion being separable by boiling water into a colourless *substance*, crystallising in leaflets, m. p. 72°, and a yellow, amorphous substance, m. p. 123° (approx.). The acidic portion of the reaction product contained formic and phthalic acids, together with a third substance, m. p. 174°, probably homophthalic acid.

Naphthalene proved quite resistant to autoxidation, but tetrahydronaphthalene (Bamberger and Kitschelt, A., 1890, 1146) is readily oxidised, giving much resinous matter and a little phthalic acid.

D. F. T.

Influence of Substituents in Benzene on the Binary Systems. Substituted Benzene–Antimony Trihaloids. BORIS N. MENSCHUTKIN (*J. Chim. phys.*, 1912, 10, 598—611. Compare A., 1912, i, 98, 99, 100, 177).—The compounds of benzene with antimony trichloride and tribromide are of the type $2SbCl_3,C_6H_6$, but some substituted benzenes give in addition compounds of the type $SbCl_3,PhR$. Methyl-, ethyl-, propyl- and *iso*amyl-benzenes exhibit a decreasing stability in the compounds $2SbCl_3,PhR$, whereas the stability of the compounds $SbCl_3,PhR$ attains a maximum in ethylbenzene.

Antimony tribromide has less affinity for the phenyl nucleus than the chloride. Toluene gives compounds of both types, but ethyl-, propyl- and *iso*amyl-benzenes of the type $SbBr_3,PhR$ only, the ethyl compound again having the maximum stability.

Diphenyl forms the compounds $2SbCl_3,PhPh$ (stable) and
$$2SbBr_3,PhPh$$
(unstable), and diphenylmethane gives two stable compounds of the same types. Triphenylmethane, however, does not combine with antimony tribromide, and with the chloride gives only an unstable compound of the formula $SbCl_3,CHPh_3$.

The xylenes form with antimony trichloride compounds of both types, which are intermediate in stability between those of toluene and ethylbenzene. *p*-Xylene gives the most, and *m*-xylene the least, stable. With antimony tribromide, *p*-xylene gives only the compound $2SbBr_3,C_6H_4Me_2$, which is intermediate in stability between those of benzene and toluene, whilst *m*- and *o*-xylene give also compounds, $SbBr_3,C_6H_4Me_2$, which are less stable than that of toluene.

The compounds of antimony trichloride and tribromide with cymene are analogous in composition and inferior in stability to those of *p*-xylene. The unfavourable influence of the *iso*propyl group is thus manifest in presence of the methyl group.

Mesitylene and ψ-cumene form compounds of both types with antimony trihaloids, those of ψ-cumene being less and those of mesitylene more stable than the toluene compounds. Apparently the three methyl groups in mesitylene neutralise each other's effects on the phenyl nucleus.   R. J. C.

Influence of Substituents in Benzene on the Properties of the Binary Systems Formed by Substituted Benzenes and Antimony Trichloride or Tribromide. BORIS N. MENSCHUTKIN (*J. Chim. phys.*, 1912, **10**, 612—623. Compare A., 1912, i, 193).— The compounds of monosubstituted benzenes with antimony trichloride are all of the two types $2SbCl_3,PhR$ and $SbCl_3,PhR$. When R is H, OH, Me, OMe, Et, Pr^a or $C_5H_{11}^{\beta}$, both compounds are formed. When R is OEt, Bz, Ph, COH, COMe, COPh, CN, compounds of the second type only are produced. When R is NO_2, F, Cl, Br, I, CHPh$_2$, compounds of the second type are also produced, which, however, decompose on melting, and when R is SO_3H, CO_2H, or COCl no combination occurs.

From the behaviour of phenol and anisole it is argued that oxygen has very little influence, although in phenetole the cumulative effect of the oxygen and the ethyl group prevents the formation of the compound $2SbCl_3,PhOEt$. Neither anisole nor ethylbenzene forms compounds of this type with antimony tribromide. Nitro-, fluoro-, chloro-, bromo-, and iodo-benzene do not combine with the tribromide at all.

m-Dinitrobenzene gives an unstable compound, $SbCl_3,C_6H_4(NO_2)_2$, which, like the compound $SbCl_3,PhI$, does not invariably crystallise out, so that complete f.p. diagrams of these systems are obtainable showing only one eutectic point. The nitro-group diminishes the affinity of the phenyl nucleus for antimony less than the halogens. *p*-Dichloro- and *p*-dibromo-benzene do not combine with antimony trichloride.

p-Chlorotoluene gives no compounds, but *o*- and *m*-chlorotoluene give compounds, $SbCl_3,C_6H_4MeCl$, which decompose on melting. No corresponding compounds of antimony tribromide exist.

The three nitrotoluenes form compounds of the formula

$$SbCl_3,C_6H_4Me\cdot NO_2,$$
the most stable being given by *o*-nitrotoluene, which also combines with antimony tribromide.

Benzene has more affinity for antimony haloids than any of its derivatives, but *cyclo*hexane does not combine at all. The degree of saturation of the phenyl nucleus varies with the nature of the substituting atoms or groups. This variation is not expressible by ordinary structural formulæ, but such formulæ as have been proposed recently by Kaufmann and by Stark are capable of giving some explanation of it.

The compounds of aniline containing 1, 2, 3, 4, and 6 molecules of aniline per molecule of antimony trichloride are in a class by themselves, and are to be attributed to the residual affinity of the amino-group.   R. J. C.

The Catalytic Action of Mercury in Nitrations. RICHARD WOLFFENSTEIN and OSKAR BOTERS (*Ber.*, 1913, 46, 586—589).— Mercury has no catalytic action on the nitration of benzene when concentrated nitric acid or a nitric acid-sulphuric acid mixture is used, nitrobenzene being formed as usual (compare Holdermann, A., 1906, i, 439). When, however, a more dilute nitric acid (D = 1·31) is used, nitro-phenols are produced. The reaction is first one of oxidation to phenol, and then nitration, since when nitrobenzene is used instead of benzene, no trace of a nitrophenol is produced. Similar reactions take place with toluene, and ethyl- and propyl-benzenes.

To prepare dinitro- or trinitro-phenol, a mixture of benzene (100 grams), nitric acid (800 grams; D = 1·31), and mercuric nitrate (15 grams) is heated on the water-bath under reflux, stirring vigorously meanwhile. At the end of the reaction, the flask contains a mass of crystals of 2 : 4-dinitrophenol and of picric acid. Additive mercury compounds are formed as intermediate products.

Instead of using nitric acid, nitrous acid, nitrogen dioxide or tetroxide, and nitrogen pentoxide may be used. For example, a mixture of 120 grams of benzene, 20 grams of mercuric nitrate, and 270 grams of nitrogen tetroxide is kept at the ordinary temperature for a few days, after which a crystalline mass of almost pure 2 : 4-dinitrophenol is obtained. T. S. P.

Hydrogenation of Aromatic Compounds by means of Platinum and Hydrogen. II. Dihydronaphthalene. RICHARD WILLSTÄTTER and VICTOR L. KING (*Ber.*, 1913, 46, 527—535. Compare Willstätter and Hatt, A., 1912, i, 545).—Dihydronaphthalene has not previously been prepared free from contamination with naphthalene or tetrahydronaphthalene. It may be obtained pure by distilling the quaternary hydroxide of tetrahydro-β-naphthylamine in a vacuum, or more conveniently by reducing naphthalene dibromide by means of zinc powder and alcohol at 60°. Pure dihydronaphthalene is a colourless oil with a sweet odour, b. p. 84·5°/16 mm., D_1^{20} 0·9974 ; it crystallises in large plates, m. p. − 9°.

When hydrogenated by means of platinum and hydrogen, the first stage is the formation of tetrahydronaphthalene, the one nucleus only being saturated. The further reduction to a completely saturated perhydronaphthalene takes place very slowly.

Naphthalene under similar conditions yields no tetrahydronaphthalene at any stage of the process, but a mixture of naphthalene and perhydronaphthalene, $C_{10}H_{18}$, is always obtained. This behaviour is not in accord with an aromatic-olefinic structure for naphthalene, such as proposed by Willstätter and Waser (A., 1912, i, 18). E. F. A.

Derivatives of *p*-Xylene. JAN J. BLANKSMA (*Chem. Weekblad*, 1913, 10, 136—141. Compare A., 1910, i, 661).—The melting-point curve of mixtures of 2 : 3-dinitro-*p*-xylene and 2 : 6-dinitro-*p*-xylene has been plotted, and a number of derivatives of *p*-xylene have been prepared. The curve indicates the formation of an additive product containing equimolecular proportions of the two substances.

Reduction of 2 : 5-dinitro-*p*-xylene with ammonium sulphide yields

5-nitro-*p*-2-xylidine, m. p. 142°, converted by Sandmeyer's reaction into 2-bromo-5-nitro-*p*-xylene, colourless crystals, m. p. 70°, which is reduced by iron powder and sulphuric acid to 5-bromo-*p*-2-xylidine, colourless crystals, m. p. 96°. Acetic anhydride converts this substance into 5-*bromo*-2-*aceto*-p-2-*xylidide*, colourless crystals, m. p. 180°, also formed by the action of a solution of bromine in glacial acetic acid on 2-aceto-*p*-2-xylidide. On saponification it yields 5-bromo-*p*-2-xylidine, already mentioned. On substituting bromine for the amino-group by Sandmeyer's reaction, there is formed 2 : 5-dibromo-*p*-xylene, m. p. 75°, also produced by bromination of *p*-xylene.

Bromine dissolved in glacial acetic acid transforms 5-nitro-*p*-2-xylidine into 3-*bromo*-5-*nitro*-p-2-*xylidine*, pale yellow crystals, m. p. 125°, converted by acetic anhydride and a trace of concentrated sulphuric acid into 3-bromo-5-nitro-2-aceto-*p*-2-xylidide, colourless crystals, m. p. 208°. Replacement of the amino-group in 3-bromo-5-nitro-*p*-2-xylidine produces 2 : 3-*dibromo*-5-*nitro*-p-*xylene*, colourless crystals, m. p. 99°.

Bromine in glacial acetic acid reacts with *p*-2-xylidine, forming 3 : 5-dibromo-*p*-2-xylidine, m. p. 65°, converted by diazotisation and the action of boiling alcohol into 2 : 6-*dibromo*-p-*xylene*, colourless plates of mother-of-pearl lustre, m. p. 32°, also obtained in an impure liquid form by the bromination of *p*-xylene. Nitration in presence of sulphuric acid converts 2 : 6-dibromo-*p*-xylene into 2 : 6-*dibromo*-3 : 5-*dinitro*-p-*xylene*, colourless crystals, m. p. 190°.

3 : 5-Dibromo-*p*-2-xylidine is converted by acetic anhydride and concentrated sulphuric acid into 3 : 5-dibromo-2-aceto-*p*-2-xylidide, colourless crystals, m. p. 192° (not 165°, as stated in *Rec. trav. chim.*, 1906, 25, 362). This substance is transformed by nitric and sulphuric acid into 3 : 5-*dibromo*-6-*nitro*-2-*aceto*-p-2-*xylidide*, colourless crystals, m. p. 256°, which is hydrolysed to 3 : 5-*dibromo*-6-*nitro*-p-2-*xylidine*, yellow crystals, m. p. 176°, also formed by bromination of 6-nitro-*p*-2-xylidine. By diazotisation and the action of boiling alcohol, this substance yields 3 : 5-*dibromo*-2-*nitro*-p-*xylene*, colourless crystals, m. p. 83°, which is converted by nitric and sulphuric acid into 3 : 5-dibromo-2 : 6-dinitro-*p*-xylene, already mentioned.

Replacement of the amino-group in 6-nitro-*p*-2-xylidine by bromine by the Sandmeyer reaction produces 2-*bromo*-6-*nitro*-p-*xylene*, pale yellow crystals, m. p. 38°.   A. J. W.

Kinetics of Ammonium Salts. EDGAR WEDEKIND and F, PASCHKE (*Zeitsch. physikal. Chem.*, 1913, 82, 314—324).—Polemical, an answer to von Halban (A., 1911, i, 852 ; compare also A, 1909, ii, 722 ; 1908, i, 723 ; 1911, i, 628). Several new preliminary experiments are given. It is shown that the addition of an inactive non-decomposable salt to a chloroform solution of an active iodide does not decrease the dissociation of the active iodide, but brings about a double decomposition, thus :

$$d\text{-NMePrPh}(C_7H_7)I + r\text{-NMePrPh}(C_7H_7)\cdot NO_3 \rightleftarrows$$
$$r\text{-NMePrPh}(C_7H_7)I + d\text{-NMePrPh}(C_7H_7)\cdot NO_3,$$
and of these four substances the iodides alone can dissociate, so that the decrease in the rate of dissociation, which is determined polari-

metrically, is explained.   The remaining and unchangeable activity is
due to the active nitrate which exists together with inactive nitrate in
the solution.   The latter can be precipitated by ether, and the amount
of active nitrate determined, which is always found to be equal in
concentration to that of the inactive nitrate added.   Preliminary
experiments are given on the rate of formation of phenylbenzylmethyl·
propylammonium bromide in chloroform solution at various tempera-
tures from methylpropylaniline and benzyl bromide.   J. F. S.

The Kinetics of Ammonium Salts.   Hans von Halban (*Zeitsch,
physikal. Chem.*, 1913, 82, 510—512).—Polemical, an answer to
Wedekind and Paschke's criticism (preceding abstract) of Halban's
paper (A., 1911, i, 852).   J. F. S.

Nitro-derivatives of Cresyl Oxides [Tolyl Ethers].   Alphonse
Mailhe (*Bull. Soc. chim.*, 1913, [iv], 13, 169—173).—Most of this
work has been published already (this vol., i, 173, 261). *p*-Tolyl ether
on nitration yields only a *tetranitro*-derivative, m. p. 84°, crystallising
in yellow needles, and furnishing on boiling with a dilute solution of
potassium hydroxide an amorphous, red powder which does not melt
at 300°.   T. A. H.

Nitro-derivatives of Cresylene Oxides [Tolylene Oxides].
Alphonse Mailhe (*Bull. Soc. chim.*, 1913, [iv], 13, 173—176. Com-
pare this vol., i, 261).—Part of this work has been published already
(*loc. cit.*). *p*-Tolylene oxide, m. p. 166°, on nitration in acetic acid
solution at 80° yields a mixture of the *mono*- and *dinitro*-derivatives.
The former has m. p. 197°, and is sparingly soluble in boiling alcohol.
The dinitro-derivative has m. p. 136°, and is readily soluble in boiling
alcohol ; it alone is formed when the nitration is effected in sulphuric
acid solution in the cold.   No higher nitro-derivative of the para-ether
could be obtained, whence the author considers that the union of the
two nuclei is in the ortho-position to the ether linking, whilst in
o-tolylene oxide (*loc. cit.*) it is in the meta-position.   T. A. H.

Preparation   of   Halogenated   Aminonaphtholsulphonic
Acids.   Farbenfabriken vorm Friedr. Bayer & Co. (D.R.-P.
254715).—Substituted aminonaphtholsulphonic acids can be readily
prepared by the halogenation of the *ON*-diacyl derivatives of 2-amino-
naphtholsulphonic acids with subsequent elimination of the acyl groups.
5-*Chloro*-6-*amino*-1-*naphthol*-3-*sulphonic acid* crystallises from water as
a colourless powder.   5-*Bromo-di*-p-*tolylsulphonyl*-6-*amino*-1-*naphthol*-
3-*sulphonic acid* is a yellow, crystalline powder.   The preparation
of 8-*bromo*-6-*amino*-1-*naphthol*-3-*sulphonic acid* is also described.
                                                          F. M. G. M.

3-Aminophenyl Mercaptan.   Theodor Zincke and Joh. Muller
(*Ber.*, 1913, 46, 775—786).—The preparation of 3-*aminophenyl
mercaptan* and of 3-*aminophenyl methyl sulphide* is described.   A
number of derivatives of the latter have been investigated.
Acetylaniline-m-*sulphonyl chloride*, $NHAc·C_6H_4·SO_2Cl$, is formed by

the action of phosphorus pentachloride on the corresponding sodium salt. It forms white needles, m. p. 88°, and is readily converted into the *amide*, m. p. 217°, and the *anilide*, m. p. 179°. Reduction of an alcoholic solution of the chloride by means of zinc dust transforms it into $3:3'$-*diacetylaminodiphenyl disulphide*, $S_2(C_6H_4\cdot NHAc)_2$, m. p. 210°, from which $3:3'$-*diaminodiphenyl disulphide*, colourless needles, m. p. 52°, is obtained by hydrolysis. The corresponding *hydrochloride* dissolves freely in water, whilst the *nitrate* and *sulphate* are sparingly soluble. When an alcoholic solution of the hydrochloride is boiled with sodium sulphide in the presence of a small quantity of sodium hydroxide, 3-aminophenyl mercaptan, b. p. 180—190°/16 mm., is formed as a pale yellow oil, which, when pure, is fairly stable towards air, but is readily oxidised when impure. Ferric chloride converts it into the disulphide. The *hydrochloride* and *sulphate* were examined. It forms a *diacetyl* derivative, m. p. 97°. With alcoholic benzaldehyde, it yields a *benzylidene* derivative, $CHPh(S\cdot C_6H_4\cdot N:CHPh)_2$, yellow powder, m. p. 59° (compare A., 1912, i, 257).

3-*Acetylaminophenyl methyl sulphide*, $NHAc\cdot C_6H_4\cdot SMe$, needles, m. p. 75°, is obtained by reducing $3:3'$-diacetylaminodiphenyl disulphide in alcoholic solution by means of sodium sulphide in the presence of sodium hydroxide and treatment of the product so obtained with methyl sulphate. Bromine converts it into a *perbromide*, which is readily transformed into a dibromo-substitution *product*. When a solution of it in chloroform is cooled in ice and saturated with chlorine, a pentachloro-*compound*, needles, m. p. 160°, probably having annexed formula, is obtained, which, when heated with aniline, yields triphenylguanidine and *dichloro-3-acetylaminophenyl mercaptan*, m. p. 152°. Hydrolysis of 3-acetylaminophenyl methyl sulphide by means of hydrochloric acid in aqueous alcoholic solution yields the *hydrochloride* of 3-aminophenyl methyl sulphide, from which the free *base*, pale yellow oil, b. p. 163—165°/16 mm., is obtained by means of ammonia. The *sulphate* was examined.
3-*Methylthiolphenyltrimethylammonium iodide*, $SMe\cdot C_6H_4\cdot NMe_3I$, m. p. 183—185° (decomp.), is obtained by the action of excess of methyl iodide on a methyl-alcoholic solution of 3-acetylaminophenyl methyl sulphide. It forms a di-iodo- and a tetra-iodo additive product. The free *base* is obtained by evaporation of its solution in a vacuum as yellowish-white, hygroscopic crystals.

3-*Methylthiolphenyltrimethylammonium chloride*, obtained from the corresponding iodide and silver chloride, forms white, hygroscopic needles. It yields a pale yellow, stable *platinichloride*, and an orange-yellow *dichromate*.

3-*Dimethylaminophenyl methyl sulphide*, pale yellow oil, b. p. 165—167°/16 mm., is obtained when the above iodide is heated above its m. p. under diminished pressure. It forms a readily soluble *hydrochloride* and *sulphate*.

3-Acetylaminophenyl methyl sulphide is oxidised by hydrogen peroxide in glacial acetic acid solution to the corresponding *sulphoxide*, $NHAc\cdot C_6H_4\cdot SO\cdot CH_3$, needles, m. p. 112°; this is converted by

hydrogen bromide into a *perbromide*, which readily passes into a mono-bromo-substitution *product*. When heated with aqueous alcoholic potassium hydroxide the above acetyl derivative is transformed into *3-aminophenylmethylsulphoxide*, colourless, rhombic leaflets, m. p. 115°. The *hydrochloride*, white needles, is readily soluble in water.

3-*Acetylaminophenylmethylsulphone*, $NHAc \cdot C_6H_4 \cdot SO_2Me$, obtained by the action of a larger quantity of hydrogen peroxide on a solution of 3-acetylaminophenyl methyl sulphide in glacial acetic acid (compare above), forms small, white needles, m. p. 137°, and is converted by aqueous alcoholic hydrogen chloride into 3-*aminophenylmethylsulphone*, m. p. 72°.

3-*Methylthiolbenzenediazonium chloride*, $SMe \cdot C_6H_4 \cdot N_2Cl$, is obtained in moderately stable, yellow leaflets by the addition of amyl nitrite to an alcoholic solution of the hydrochloride of 3-aminophenyl methyl sulphide in the presence of alcoholic hydrogen chloride. It couples with dimethylaniline and with β-naphthol, yielding dyes which crystallise in red needles. It decomposes when heated with water, but a phenol could not be isolated from the product of the reaction. It was transformed by the usual methods into 3-*methylthiolbenzonitrile*, white needles, m. p. 40° (3-*methylthiolbenzoic* acid, leaflets, has m. p. 129°), and 3-*methylthiolphenyl iodide*, almost colourless oil, b. p. 157°/16 mm.

3 : 3′-Diacetylaminodiphenyl disulphide is converted into the corresponding ammonium *iodide*, $S_2(C_6H_4 \cdot NMe_3I)_2$, m. p. 185—186° (decomp.), when heated with methyl alcohol and methyl iodide; this substance, when heated under diminished pressure, yields 3 : 3′-*dimethylaminodiphenyl disulphide*, $S_2(C_6H_4 \cdot NMe_2)_2$, colourless oil, b. p. 162—166°/16 mm. A solution of the latter in formic acid is converted by amyl nitrite in the presence of a little hydrochloric acid into 6 : 6′-*dinitroso*-3 : 3′-*dimethylaminodiphenyl disulphide*,

$$S_2(C_6H_3[NO] \cdot NMe_2)_2,$$

dark green needles, m. p. 130°, which is reduced by hydrogen sulphide in ammoniacal solution to 6-*amino*-2-*dimethylaminophenyl mercaptan*. The *hydrochloride* of the latter, white needles, m. p. 235° (decomp.), was investigated. It forms a colourless double *salt* with mercuric chloride. With potassium ferricyanide, it yields a dark green *precipitate*, the colour of which deepens on addition of alkali. Ferric chloride converts it into a dark red oxidation *product*, which yields a dark violet double *salt* with mercuric chloride. Hydrogen sulphide decomposes the latter, the original mercaptan being regenerated.

<div style="text-align:right">II. W.</div>

Basic Properties of Sulphoxides and their Position Among the Organo-metallic Bases. EMIL FROMM (*Annalen*, 1913, **396**, 75—103).—The similarities in behaviour between bases of the type $R_{n+1}Md \cdot OH$ (where Md represents a metalloid element such as N, P, As, Sb, O, S, Se, Te, or I, and n the number of atoms of hydrogen with which it can unite, and R an organic radicle) have frequently been emphasised. Compounds of the type MdR_n may be regarded as the anhydrides of $R_{n+1}Md \cdot OH$. All these bases are monoacidic.

The anhydrides, R_nMdO, of a second series of bases of the type $R_nMd(OH)_2$ are known. In the anhydrides, Md may be any one of the elements given above, but in the hydroxides hitherto Md has been only N, P, As, Sb, or Te. All these bases and their anhydrides are diacidic, and the anhydrides or their salts are characterised by the three equilibrium reactions: (i) $R_nMdO \rightleftharpoons R_nMd + O$; (ii) $R_nMdX_o \rightleftharpoons R_nMd + X_2$ (where X is halogen); (iii) $R_nMdCl_2 + H_2O \rightleftharpoons R_nMdCl \cdot OH + HCl \rightleftharpoons R_nMdO + 2HCl$.

In the present communication the author deals with substances in which Md is sulphur, and, therefore, $n = 2$. Sulphoxides can be prepared by reaction (i), the oxygen being supplied by nitric acid, hydrogen peroxide, or chromic acid, and also by reactions (ii) and (iii). The dichlorides of diaryl sulphides have been prepared by Fries and Vogt (A., 1911, i. 538), and are converted into sulphoxides by water; di-iodides of dialkyl sulphides, which have long been known, are, it is now shown, converted into sulphoxides by silver acetate.

It is also shown that sulphoxides can combine with one equivalent of hydrogen chloride to form hydrogen salts, $OH \cdot SR_2Cl$, and with two equivalents of hydrogen bromide or iodide to form normal salts, R_2SX_2, which are identical with the dibromides or di-iodides produced by reaction (ii). The hydrogen salts and the normal salts are both hydrolysed more or less rapidly by water, reproducing the sulphoxide. In addition to hydrolysis, the normal salts can also dissociate according to reaction (ii), and it depends on the relative velocities of dissociation and of hydrolysis whether a normal salt yields the sulphoxide or the sulphide by treatment with aqueous alkali hydroxide or silver acetate. The parent substance, H_2SO, of the sulphoxides, and its tautomeric form, $HS \cdot OH$, are unknown; anthraquinone derivatives of both have been described by Fries (A., 1912, i, 1005).

The relations between disulphides and disulphoxides and the basic properties of the latter can be represented by equations similar to (i), (ii), and (iii).

[With FRITZ SCHÄFER, AQUILA FORSTER, and BORIS VON SCHER-SCHEWITZKI.]—o-Nitrophenyl benzyl sulphide and the para-isomeride, 2 : 4-dinitrophenyl benzyl sulphide, dinitrophenyl methyl sulphide, and s-di-o-nitrophenylthiolethane, resemble di-p-tolyl sulphide (Fromm and Raiziss, A., 1910, i, 554) in not forming additive compounds with bromine; 2 : 4-dinitrophenyl benzyl sulphide in cold chloroform yields *bromodinitrophenyl benzyl sulphide*, $C_6H_3Br(NO_2)_2 \cdot S \cdot CH_2Ph$, m. p. 104°, yellow needles. Also the dibromides cannot be obtained from the sulphoxides and hydrogen bromide. Both reactions proceed, however, when the nitro-groups are reduced to amino-groups and the latter acetylated; thus di-o-acetylaminophenylthiolethane and bromine in cold chloroform yield the *tetrabromide*, $C_2H_4(SBr_2 \cdot C_6H_4 \cdot NHAc)_2$, m. p. 60—61°, unstable, orange crystals, which is converted by water into *di-*o-*acetylaminophenylsulphoxyethane*, $C_2H_4(SO \cdot C_6H_4 \cdot NHAc)_2$, m. p. 214°, colourless needles; the latter and hydrogen bromide in chloroform regenerate the tetrabromide.

Dibenzyl sulphide and chlorine in petroleum at 0° yield the very unstable *dichloride*, $SCl_2(CH_2Ph)_2$, which is converted into the sulphoxide by water. The dibromide is more stable (Fromm and

Raiziss, *loc. cit.*). The *di-iodide*, $SI_2(CH_2Ph)_2$, m. p. 64—65°, violet crystals, prepared from the sulphide and iodine in glacial acetic acid on the water-bath, is extremely stable. It is decomposed, without hydrolysis, by dilute sodium hydroxide, dibenzyl sulphide being regenerated; the hydrolysis is effected by silver acetate in dilute acetic acid, whereby dibenzylsulphoxide is produced.

Dibenzylsulphoxide and hydrogen iodide in chloroform at 0° yield the preceding dibenzyl sulphide di-iodide. The sulphoxide and hydrogen chloride in benzene form *dibenzylsulphoxide hydrochloride*,

$$OH \cdot SCl(CH_2Ph)_2,$$
m. p. 90°, colourless crystals, which does not further react with hydrogen chloride, and is decomposed into the sulphoxide by water or in a vacuum.

s-Dibenzylthiolethane reacts with chlorine in cold petroleum to form the unstable *tetrachloride*, $C_2H_4(SCl_2 \cdot CH_2Ph)_2$, white crystals, with bromine in cold chloroform to form the moderately stable *tetrabromide*, m. p. 84°, orange-red crystals, and with iodine in boiling glacial acetic acid to form the *tetraiodide*, m. p. 94°, red needles. The tetrachloride and the tetrabromide are very rapidly converted into the disulphoxide by water. On the contrary, the disulphoxide suspended in cold petroleum or chloroform is converted into the tetrabromide by hydrogen bromide, and into a comparatively stable *dihydrochloride*,

$$C_2H_4[SCl(OH) \cdot CH_2Ph]_2,$$
by hydrogen chloride.

p-*Tolyl benzyl sulphide*, $C_6H_4Me \cdot S \cdot CH_2Ph$, m. p. 44°, prepared from *p*-tolyl mercaptan and benzyl chloride, yields the *sulphoxide*, m. p. 136—137°, by oxidation with 30% hydrogen peroxide in glacial acetic acid or with nitric acid, and reacts with chlorine or bromine in cold petroleum to form respectively the very unstable *dichloride*, $C_6H_4Me \cdot SCl_2 \cdot CH_2Ph$, and comparatively unstable *dibromide*, and with iodine in hot glacial acetic acid to form the stable *di-iodide*, m. p. 72°, dark blue plates. The dichloride and the dibromide by treatment with water, and the di-iodide by treatment with silver acetate, are converted into *p*-tolylbenzylsulphoxide; the di-iodide and aqueous sodium hydroxide yield *p*-tolyl benzyl sulphide. The dibromide and the di-iodide are obtained from the sulphoxide and hydrogen bromide or iodide in chloroform. p-*Tolyl methyl sulphide di-iodide*, $C_6H_4Me \cdot SMeI_2$, m. p. 40°, prepared from its components in petroleum, crystallises in dark blue needles.

Formaldehyde-*p*-tolylmercaptal (this vol., i, 176) forms a *tetraiodide*, $CH_2(SI_2 \cdot C_6H_4Me)_2$, m. p. 68—70°, which can also be obtained from the disulphoxide and hydrogen iodide in chloroform, and is not converted into the disulphoxide by silver acetate. Formaldehydebenzyl-mercaptal also forms a *tetraiodide*, $CH_2(SI_2 \cdot CH_2Ph)_2$, decomp. 110—140°, which is converted by silver acetate, not into the sulphoxide as usual, but into formaldehydebenzylmercaptal.

In boiling glacial acetic acid, benzyl disulphide and iodine form the *tetraiodide*, $S_2(CH_2Ph)_2I_4$, decomp. 113—120°, green crystals, which is converted into the disulphoxide by silver acetate in hot glacial acetic acid; from the latter the tetraiodide is regenerated by hydrogen iodide at −5° in carbon tetrachloride. *Benzyl disulphide tetrachloride* is

extremely unstable, and the *tetrabromide* has m. p. 2° (decomp.); the latter and silver acetate yield the disulphoxide.   C. S.

Substituted Aryl Sulphonamides. OTTO N. WITT and D. UERMÉNYI (*Ber.*, 1913, 46, 296—308).—Hinsberg's method for the preparation of secondary bases (A., 1891, 49) has not yet received general application, owing to the difficulty which has been experienced in hydrolysing the sulphonamides. For this purpose Schroeter and Eisleb (A., 1909, i, 575) dissolved the substances in cold concentrated sulphuric acid, but obtained in the case of benzenesulphonanilide, not aniline but sulphanilic acid. It is now shown that good results may be obtained with 80% sulphuric acid. The toluene-*p*-sulphonamide is suspended in this acid and heated to 135—150°, when solution and hydrolysis take place. On cooling, *p*-toluenesulphonic acid separates, and is removed by filtration, whilst the base is liberated from the diluted filtrate and distilled in steam. The yields are somewhat impoverished by the formation of non-volatile by-products, which occur to a preponderating extent in the case of ethyl-*p*-toluidine, and consist of a sulphone, being due to the displacement of the *p*-toluenesulphonic acid residue into the ring.

Toluene-*p*-sulphon-*p*-toluidide and also its *acetyl* derivative, m. p. 133·5°, give *p*-toluidine-*m*-sulphonic acid with concentrated sulphuric acid, but sulphonation of the base does not occur with 80% acid at 150°. Crude methyl- and ethyl-aniline and also methyl-*o*-toluidine (*toluene-*p*-sulphon-methyl-o-toluidide*, $C_{15}H_{17}O_2NS$, has m. p. 119—120°) may be conveniently purified by this process. *Toluene-*p*-sulphonethyl-o-toluidide*, $C_{16}H_{19}O_2NS$, forms long needles, m. p. 75°, but the ethyl-*o*-toluidine is accompanied by a small quantity of the rearranged *sulphone*, white needles, m. p. 134°. The hydrolysis of *toluene-*p*-sulphonethyl-*p*-toluidide*, colourless needles, m. p. 71—72°, gives less than a 50% yield of ethyl-*p*-toluidine, the chief product being precipitated on adding water, in colourless needles, m. p. 113°. It is formed in still greater quantity when concentrated acid is used, and is a secondary base, since it gives an *acetyl* compound, $C_{16}H_{18}O_2NS \cdot O_2H_3O$, in silky, white needles, m. p. 143—144°. When the base is heated at 275° in a current of hydrogen chloride, ethyl chloride is removed and the resulting primary *aminoditolylsulphone*, $C_{14}H_{15}O_2NS$, colourless crystals, m. p. 169°, may be diazotised and deprived of the amino-group. The resulting compound forms colourless needles, m. p. 116°, and can be synthesised by condensing the chloride of *m*-toluenesulphonic acid with toluene by means of aluminium chloride. It is, therefore, mp-*ditolylsulphone*, and the rearrangement of the sulphonamide into a sulphone is to be represented thus:

(p) Me·C_6H_4·SO_2 (p) Me·C_6H_4·SO_2
The sulphone may be nitrated in the cold, and the *mononitro*-derivative, intensely yellow needles, m. p. 161°, forms an *acetyl* compound, $NO_2 \cdot C_{16}H_{17}O_2NS \cdot C_2H_3O$, in colourless crystals, m. p. 159—160°.   J. C. W.

Preparation of p-Alkyloxyphenylaminoalkyl Sulphites. FARB-WERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 255305).—When acetaldehyde (or its higher homologues) is condensed with p alkyloxy-aminobenzenes in the presence of an alkali (or ammonium) hydrogen sulphite it furnishes salts of therapeutic value, and having the general formula OR$^1\diagdown\diagup$NH·CHR·O·SO$_2$M, where M is an alkali metal or ammonium, R = methyl or ethyl, and R^1 an alkyl group.

Sodium p-*phenetidinoethyl sulphite*, needles, is obtained when a cooled aqueous solution of 40% sodium hydrogen sulphite (110 parts) is treated with acetaldehyde (20 parts) and p-phenetidine (55 parts), and subsequently gently heated until a clear solution is obtained; on cooling, the solution sets to a crystalline mass.

The p-phenetidine can be replaced by p-anisidine, and the acetalde-hyde by propaldehyde. F. M. G. M.

Preparation of Aromatic Amino-alcohols FARBENFABRIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 254438).—The reduction of aromatic ketones to the corresponding alcohols has previously been described, and is now found to proceed quantitatively if hydrogen is employed in the presence of colloidal metals of the platinum group.

OMe$\diagdown\diagup$CH(OH)·CHMe·NH$_2$
OMe
3 : 4-*Dimethoxyphenyl-a-propanol-amine* (annexed formula), hard, colourless crystals, m. p. 138°, is obtained when 100 parts of α-aminopropionylveratrole (A., 1910, i, 313) in 300 parts of water with palladous chloride (5 parts), gum arabic (10 parts), and hydrazine hydrate are submitted to the action of hydrogen during two days at 20° and under a pressure of 1·5 atmo-

OH$\diagdown\diagup$CH(OH)·CHMe·NH$_2$
OH

spheres; the *hydrochloride*, colour-less leaflets, has m. p. 212°; whilst the reduction in a similar manner of 4-*a-aminopropionylcatechol* (A., 1910, i, 313) gives rise to a 95% yield of 3 : 4-*dihydroxyphenyl-a-propanolamine* (annexed formula), m. p. 188°; the *hydrochloride*, a colourless powder, has m. p. 95°. F. M. G. M.
Preparation of Esters of Nitroanthraquinonylanthranilic Acid. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254475).—When nitroaminoanthraquinones are treated with the esters of o-halogenated benzoic acids in the presence of copper (or a salt of copper), they give rise to nitroanthraquinonylanthranilic acid esters.

Methyl 4-nitro-1-anthraquinonylanthranilate, reddish-brown needles, m. p. 234—240°, is thus obtained from 1-nitro-4-aminoanthraquinone and methyl o-chlorobenzoate. On hydrolysis and subsequent reduction, these compounds furnish the corresponding aminoanthraquinonyl-anthranilic acids, which are of technical value. F. M G. M.

Metaquinonoids. OTTO STARK and O. GARBEN (*Ber.*, 1913, **46**, 659—666).—The method by which Thiele and Balhorn obtained yellow

tetraphenyl-p-xylylene from methyl terephthalate (A , 1901, i, 491) has been applied to methyl isophthalate, and a yellow tetraphenyl-m-xylylene of the annexed formula has been prepared.
*Tetraphenyl-*m-*xylylene glycol*, $C_{32}H_{26}O_2$, is obtained by the action of magnesium phenyl bromide on methyl isophthalate in a boiling mixture of benzene and anisole. It crystallises from glacial acetic acid with one molecule of the solvent in light yellow prisms, m. p. 88°, and from light petroleum in the free state, m. p. 112—113°. Hydrogen chloride precipitates from an acetic acid solution the *dichloride*, $C_{32}H_{24}Cl_2$, which crystallises from petroleum in white needles, m. p. 137°, and like the *dibromide*, m. p. 167—168°, can be titrated with alkali in alcoholic solution. When heated with zinc dust and Devarda's alloy in benzene (compare Schmidlin, A., 1908, i, 150), a golden-yellow solution with red fluorescence is obtained, from which petroleum precipitates *tetraphenyl*-m-*xylylene*, in yellow needles, m. p. 210—220° (decomp.). It gives the above dichloride with chlorine, but is stable towards oxygen.

When hydrogen chloride is passed into the acetic acid mother liquors of the glycol, a *dichloride* is obtained, which is insoluble in hot petroleum, and has m. p. 236—238°. It may be hydrolysed and converted into a *dimethyl ether*, $C_{34}H_{30}O_2$, m. p. 187—188°, from which the *dibromide*, m. p. 242°, is obtained. It is supposed that the $-C(OH)Ph_2$ group has wandered into the *para*-position and that the compounds are isomeric, according to Schmidlin's isomerism (A., 1912, i, 32), with tetraphenyl-p-xylylene glycol dimethyl ether, m. p. 181—182·5°, and tetraphenyl-p-xylylene dibromide, m. p. 270—272° (Thiele and Balhorn, *loc. cit.*).   J. C. W.

Direct Hydrogenation of the Phenylacetic Esters. Preparation of *cyclo*Hexylacetic Acid. PAUL SABATIER and MARCEL MURAT (*Compt. rend.*, 1913, 156, 424—427. Compare A., 1912, i, 353).—The esters of phenylacetic acid are readily hydrogenated by excess of hydrogen in the presence of very active nickel at 180°. By this means the following esters have been prepared.

Methyl cyclo*hexylacetate*, b. p. 200—202° (corr.), D_0^0 0·9961, D_0^{14} 0·9896, n_D^{14} 1·459. Ethyl *cyclo*hexylacetate, b. p. 211—212° (corr.), D_0^0 0·9626, D_0^{14} 0·9537, n_D^{14} 1·451 (compare Freundler, A., 1905, i, 890). *Propyl* cyclo*hexylacetate*, b. p. 228—229° (corr.), D_0^0 0·9560, D_0^{15} 0·9431, n_D^{15} 1·450. iso*Butyl* cyclo*hexylacetate*, b. p. 240—241° (corr.), D_0^0 0·9445, D_0^{14} 0·9307, n_D^{14} 1·452. iso*Amyl* cyclo*hexylacetate*, b. p. 250—251° (corr.), D_0^0 0·9388, D_0^{16} 0·9267, n_D^{16} 1·454.

The refractive indices are practically constant throughout, but the density diminishes regularly with increase in molecular weight. All these esters are readily saponified by alcoholic potassium hydroxide, giving the free acid, m. p. 32°.

The phenylpropionic esters undergo similar hydrogenation.

It is of interest to note that benzyl acetate, the isomeride of methyl phenylacetate, submitted to similar hydrogenation is decomposed, giving

toluene and acetic acid, at the same time destroying the activity of the nickel.

<div align="right">W. G.</div>

Esters of Cellulose with Benzoic Acid and its Derivatives. OTTO HAUSER and H. MUSCHNER (*Zeitsch. angew. Chem.*, 1913, **26**, 137—139).—In the preparation of the esters the authors used hydrocellulose, which was made according to the method of Girard. The hydrocellulose is treated, under cooling, with a large excess of benzoyl chloride and sodium hydroxide, and the resulting product washed with hot water to remove alkali, and finally with alcohol and ether. The results show that the product obtained is always cellulose monobenzoate; no dibenzoate is formed, whatever may be the concentration of the sodium hydroxide (compare Cross and Bevan, A., 1901, i, 452). The only effect of the concentration of the sodium hydroxide is on the time of reaction, the stronger the alkali the shorter the time. The best concentration is 20%, and the temperature should be kept at 20° by appropriate cooling.

*Cellulose mono-*p-*chlorobenzoate,* $C_{19}H_{28}O_{11}Cl$, was prepared similarly from hydrocellulose and *p* chlorobenzoyl chloride. It is an amorphous, white powder, insoluble in all solvents, non-hygroscopic and non-fusible. Esters could not be obtained from *m*-nitrobenzoyl chloride and *p*-bromobenzoyl chloride, owing to the fact that the high temperature necessary to melt the chloride resulted in its saponification by the sodium hydroxide before the cellulose entered into reaction. *p*-Toluoyl chloride gave a product corresponding with the formula $C_{18}H_{26}O_{11}$, instead of the expected formula $C_{20}H_{26}O_{11}$.

<div align="right">T. S. P.</div>

An Interesting Case of Dimorphism. ALEXIS DUFFOUR (*Compt. rend.*, 1913, **156**, 473—475).—Vanillyl benzoate is obtained in two distinct crystalline forms, monoclinic or triclinic, accordingly as it is prepared by the hydrogenation of vanillin benzoate in the cold in the presence of platinum black (compare Vavon, A., 1912, i, 260), or by the condensation of benzoyl chloride and sodium vanillyloxide. These two forms are both stable at the ordinary temperature, having been kept for a year unaltered. The triclinic crystals

$$[a:b:c=0.8697:1:0.5283;\ a=90°20';\ \beta=72°22';\ \gamma=72°44']$$

have m. p. 99°, whilst the monoclinic

$$[a:b:c=0.7814:1:1.3460;\ \beta=111°9'],$$

observed under a microscope, begin to melt at 90°, and in the liquid obtained, triclinic crystals begin to form, transforming the whole into a friable mass only melting at 99°. This transformation of the monoclinic into the triclinic form when the two are in contact is retarded by diminution in temperature and becomes inappreciable at 30°.

<div align="right">W. G.</div>

Nitration of Benzoic Acid in the Presence of Mercury RICHARD WOLFFENSTEIN and W. PAAR (*Ber.*, 1913, **46**, 589—599).— When benzoic acid (50 grams) is nitrated with nitric acid (300 grams; D = 1·35) in the presence of mercuric nitrate, 2 : 4 : 6-trinitro-*m*-hydroxybenzoic acid is obtained. The mixture is heated on the brine-bath at

105° for twenty hours, after which it is filtered from unchanged benzoic acid, the filtrate made alkaline to remove the mercury, acidified, and then extracted with ether to dissolve out any m-nitrobenzoic acid formed. The aqueous solution is then concentrated in order to obtain crystals of the readily soluble 2 : 4 : 6-trinitro-m-hydroxybenzoic acid. Various trinitrohydroxybenzoic acids have been described in the literature, and in order to compare them with the above acid they have been again prepared by the authors. Shardinger (A., 1876, 584) obtained an acid by the nitration of anthraflavone. Since anthraflavone is a mixture of the two isomerides, anthraflavic acid and 1 : 7-dihydroxyanthraquinone, the authors have nitrated each of these substances. In each case a tetranitro-derivative is first obtained, which undergoes fission, on further action of nitric acid, with the formation of the above-mentioned 2 : 4 : 6-trinitro-m-hydroxybenzoic acid. The third isomeride of anthraflavic acid is anthrarufin, the tetranitro-derivative of which has been prepared by Liebermann (A., 1879, 537). This on boiling with nitric acid undergoes fission with the formation of the above acid. Tetranitroanthrarufin is therefore 3 : 4 : 6 : 8-tetranitro-1 : 5-dihydroxyanthraquinone. Beilstein and Geitner (*Annalen*, 1866, 139, 12) obtained a trinitrohydroxy-acid by the action of fuming nitric acid on m-aminobenzoic acid, and this the authors prove to be identical with their acid.

2 : 4 : 6-Trinitro-m-hydroxybenzoic acid, $C_7H_3O_9N_3$, crystallises with one molecule of water of crystallisation, in rhombic tablets ; m. p. 180°. It forms a series of salts, characterised by their water of crystallisation. The *sodium, potassium, barium,* and *silver* salts have $2H_2O$, and the *copper* salt, $5H_2O$. Its constitution was proved by its conversion into picric acid when heated in small quantities (0 2 gram) at a time at 195°. The simplest method of preparation is from m-hydroxybenzoic acid. Five grams of this acid are dissolved in 30 grams of fuming nitric acid (D = 1·52), and the solution heated on the water-bath. The nitric acid is expelled on the water-bath, the residue again evaporated down with nitric acid, then with water, and finally extracted with benzene, leaving the pure acid.   T. S. P.

2 : 4 : 6-Trinitro-m-hydroxybenzoic Acid. RICHARD WOLFFEN-STEIN and W. PAAR (*Ber.*, 1913, 46, 680—682. Compare preceding abstract).—E. F. Smith (*Proc. Amer. Phil. Soc.*, 25) described a compound, which he obtained by treating ethyl m-hydroxybenzoate with nitrous acid and then with an excess of potassium hydroxide, as a trinitro-m-hydroxybenzoic acid, basing his formula on an estimation of potassium in the monopotassium salt. It might be expected that the hydroxyl hydrogen should also have been replaced by potassium and that the acid might be identical with Wolffenstein and Paar's compound. These authors have repeated Smith's experiment, and find that the product is in reality an ester which cannot be hydrolysed by prolonged boiling with alcoholic or aqueous potash, and is therefore, according to Victor Meyer's rule that ortho-substituents protect a carboxyl or ester group, *ethyl* 2 : 6-*dinitro*-m-*hydroxybenzoate*. It has m. p. 117°.
                                                                J. C. W.

Action of Hydrogen Cyanide on *p*-Nitrobenzaldehyde.
GUSTAV HELLER [with OTTO FRITSCH] (*Ber.*, 1913, **46**, 280—294)
—When *p*-nitrobenzaldehyde is suspended in glacial acetic acid and
shaken with a concentrated aqueous solution of potassium cyanide
until dissolved, it is converted into *p*-nitromandelonitrile, which may
be precipitated by water. The behaviour of this substance towards
various reagents, its conversion into nitro- and amino-mandelic acid,
and attempts to form anhydrides of the latter acid are described.

p-*Nitromandelonitrile*, $NO_2 \cdot C_6H_4 \cdot CH(OH) \cdot CN$, crystallises from
benzene in faintly yellow needles, m. p. 109—110°, which on hydrolysis
with hydrochloric acid readily yield *p*-nitromandelic acid. Towards
sodium hydroxide it is very sensitive, and from the product of the re-
action, *p*-nitroso-, *p*-nitro-, and *p* azoxy-benzoic acids have been isolated.

a-*Benzoyloxy*-p-*nitrophenylacetic* acid, $NO_2 \cdot C_6H_4 \cdot CH(OBz) \cdot CO_2H$, is
obtained by benzoylating the acid in pyridine solution, in yellowish-
white prisms, m. p. 185—186°. It is easily hydrolysed, and all
attempts to reduce it resulted in the production of benzoic acid. The
reduction of *p*-nitromandelic acid itself follows different courses ; with
zinc and acetic acid it results in p-*azoxymandelic acid*, $C_{18}H_{14}O_7N_2$,
in yellow needles, which darken at 190°; with stannous chloride the
product is *p*-aminophenylacetic acid; ferrous sulphate and ammonia
lead to p-*aminomandelic* acid, $NH_2 \cdot C_6H_4 \cdot CH(OH) \cdot CO_2H$, which forms
faintly yellow needles from warm water, and a colourless *hydrochloride*.
When warmed for a long time in water, it gradually deposits a yellow
anhydride, $(C_8H_7O_2H)_x$, m. p. 210° (decomp.), which is insoluble in
organic solvents. *p*-Aminomandelic acid yields a normal *benzoyl*
derivative in sodium carbonate solution as a crystalline powder, m. p.
218°, which does not lose water when heated with acetic anhydride, but

when benzoylated in pyridine in the cold, the
product is β-*hydroxy*-1-*benzoylindole* (annexed
formula).
This substance could only be obtained as a
colourless, amorphous powder, which was not
readily attacked by warm aqueous alkali, but
was hydrolysed by cold alcoholic potash to *p*-benzoylamino-
mandelic acid.
If the solution of *p*-nitrobenzaldehyde in concentrated potassium
cyanide and acetic acid is not immediately precipitated by water,
but is left for a day, pp'-*dinitrodeoxybenzoin cyanide*,
$$NO_2 \cdot C_6H_4 \cdot CO \cdot CH(CN) \cdot C_6H_4 \cdot NO_2,$$
is deposited. This crystallises in pale yellow needles, m. p.
267—268°, cannot be acetylated, and gives no reaction with ferric
chloride. On reduction it yields *p*-aminobenzoic acid, and when
dissolved in hot sodium hydroxide it deposits *p*-azoxybenzoic acid.
When the red solution in cold sodium hydroxide is at once filtered into
hydrochloric acid, however, 4-*nitro*-4'-*nitrosostilbene*-αβ-*diol*,
$$NO_2 \cdot C_6H_4 \cdot C(OH) \cdot C(OH) \cdot C_6H_4 \cdot NO,$$
can be extracted by means of boiling water from the precipitate. It
forms colourless leaflets, m. p. 225° (decomp.), which give an intense,
dark red colour with ferric chloride, and form acetyl and benzoyl
derivatives which could not be obtained pure. J. C. W.
Preparation of Carboxydiarylhydrols. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254122).—6-*Hydroxy*-2 : 4 *dimethylbenzoic acid*, m. p. 66°, is prepared by the action of carbon dioxide on *s*-xylenol; when it is slowly added to a cooled solution of *p*-diethylaminobenzaldehyde (1 mol.) in concentrated sulphuric acid, it gives rise to a *hydrol*, which can be further condensed with *o*-hydroxytoluic acid to yield *compounds*, which dye wool in violet shades.

Similar *compounds* are also described from *o*-chloro-*p*-diethylaminobenzaldehyde with *m*-hydroxytoluic acid, and its further condensation with *o*-hydroxytoluic acid; from *o*-chlorobenzaldehyde with 6-hydroxy-2:4-dimethylbenzoic acid, followed by condensation with *o*-hydroxytoluic acid, whilst the tinctorial properties of other similar compounds are tabulated in the original.   F. M. G. M.

Preparation of 2-Halogen-5-acylaminobenzoylbenzoic Acid. AKTIEN-GESELLSCHAFT FUR ANILIN-FABRIKATION (D.R.-P. 254091).— 3-Aminobenzoylbenzoic acid (annexed formula) and its homologues can be readily acetylated by ordinary methods, and on subsequent halogenation (in the same solution) yield 2-halogen-5-acetylaminobenzoylbenzoic acid.
The following compounds are described: 6-*Bromo*-3-*acetylaminobenzoylbenzoic acid*, hard crystals, m. p. 218°; 6-*bromo*-3-*acetylamino*-p-*toluoylbenzoic acid* (prepared from 3-amino-*p*-toluoylbenzoic acid), colourless needles, m. p. 226°; 2-*bromo*-5-*acetylamino*-4-*carboxybenzoylbenzoic acid* (from 3-amino-4-carboxybenzoylbenzoic acid, m. p. 265°), short, colourless, rod-like crystals, m. p. 264—266°, and 2-*chloro*-5-p-*toluenesulphonyl*-p-*toluoylbenzoic acid*, colourless rods, m. p. 135°.   F. M. G. M.

α-Hydroxy-γ-phenylcrotonic Acid. An Example of an Ether of a Ketone Hydrate. J. BOUGAULT (*Compt. rend.*, 1913, 156, 555—556).—The acid amide, $C_{20}H_{23}O_6N$, obtained by the hydrolysis of α-hydroxy-γ-phenylcrotonamide (compare this vol., i, 269) on treatment with potassium permanganate in dilute acid solution gives a *compound*, $C_{20}H_{19}O_8N$, m. p. 120°, to which the author assigns the annexed constitution. The presence of the imide group in the compound is shown (1) by its pseudo-acid properties; (2) by its transformation into an *acid amide*, $C_{20}H_{21}O_4N$, m. p. 171°, and finally to the dibasic *acid*, $C_{20}H_{20}O_5$, m. p. 204°, by the action of dilute alkali hydroxides; (3) by the formation of a N-*methyl* derivative, m. p. 86°, which liberates methylamine on treatment with alkali. The compound, unlike the acid amide from which it is prepared (*loc. cit.*), is not readily decomposed by alkalis to give benzylpyruvic acid. Its preparation by the elimination of two tertiary hydroxyl groups appears to be the reverse of Wagner's action.   W. G.
Preparation of Esters of Acetylsalicylic [o-Acetoxybenzoic] Acid. RICHARD WOLFFENSTEIN and JOSEF ZELTNER (*Ber.*, 1913, 46, 582—586).—Attempts to prepare ethyl o-acetoxybenzoate by the action of o-acetoxybenzoyl chloride on ethyl alcohol led to the isolation of ethyl salicylate, ethyl acetate, salicylic acid, and salicylic anhydride, the primarily formed ethyl o-acetoxybenzoate being decomposed by the hydrogen chloride liberated during the reactions. Satisfactory results were, however, obtained when the reaction was carried out in the presence of a substance capable of absorbing hydrogen chloride, for example, quinoline.

*Trichloro*isopropyl o-*acetoxybenzoate* was obtained by heating a a mixture of o-acetoxybenzoyl chloride, trichloroisopropyl alcohol, and dimethylaniline on the water-bath during two hours. It had m. p. about 65°, and could not be distilled without decomposition. Occasionally this ester was obtained in an oily form, which could not be caused to crystallise, but which, according to analysis, was pure.

Trichloro-tert.-*butyl* o-*acetoxybenzoate*, m. p. 55—57°, after previous softening, b. p. about 180°/16 mm. (slight decomp.), was obtained by heating o-acetoxybenzoyl chloride and *tert.*-trichlorobutyl alcohol at 140° in the presence of barium carbonate. H. W.

Preparation of Chloroanthraquinonecarboxylic Acids. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P., 255121).—The method previously described (A., 1911, i, 466), in which anthraquinone was chlorinated in sulphuric acid solution in the presence of iodine, has now been extended to the anthraquinone-α- and β-carboxylic acids.

When anthraquinone-β-carboxylic acid dissolved in fuming sulphuric acid (in the presence of iodine) is chlorinated at 125°, it gives rise to a *dichloroanthraquinonecarboxylic acid*, yellow crystals, m. p. above 300°, which when heated with p-toluidine furnishes an intensely green quinazarin-like derivative, thus indicating that the chlorine atoms are in the para-position with regard to each other.

The analogous compound from anthraquinone-α-carboxylic acid crystallises from acetic acid, and has m. p. 240—241°. The anthraquinonedicarboxylic acids can also be employed in this reaction. F. M. G. M.

Saturated δ-Ketonic Esters and their Derivatives. DOROTHY A. HAHN AND ANGIE G. ALLBEE (*Amer. Chem. J.*, 1913, 49, 171—179).— Kohler (A., 1911, i, 384) has described a general method for the preparation of unsaturated δ-ketonic esters; this method has now been applied to the production of the corresponding saturated compounds.
Ethyl β-anisoyl-α-phenylethylmalonate,
$$OMe \cdot C_6H_4 \cdot CO \cdot CH_2 \cdot CHPh \cdot CH(CO_2Et)_2,$$
m. p. 78°, obtained by the condensation of ethyl malonate with anisyl styryl ketone in presence of piperidine, crystallises in plates or stout needles. The corresponding *methyl* ester, m. p. 104°, forms plates or slender needles. When an alcoholic solution of the ethyl ester is treated with concentrated aqueous solution of potassium hydroxide, the *potassium* salt of β-anisoyl-α-phenylethylmalonic acid separates, which

is converted by acids into the *potassium hydrogen* salt and subsequently into the acid itself.   *β-Anisoyl-α-phenylethylmalonic acid*, m. p. 165° (decomp.), crystallises from water in slender needles containing water of crystallisation, which is eliminated below 130°.   By the action of bromine on a solution of ethyl β-anisoyl-α-phenylethylmalonate in chloroform, the *β-bromo*-derivative,

$$OMe \cdot C_6H_4 \cdot CO \cdot CHBr \cdot CHPh \cdot CH(CO_2Et)_2,$$
m. p. 97°, is obtained, which forms large, six-sided prisms.

When β-anisoyl-α-phenylethylmalonic acid is heated at 165—170° until the evolution of carbon dioxide ceases, *γ-anisoyl-β-phenylbutyric acid*, $OMe \cdot C_6H_4 \cdot CO \cdot CH_2 \cdot CHPh \cdot CH_2 \cdot CO_2H$, m. p. 152°, is obtained, which crystallises in plates or prisms; its *methyl* ester, m. p. 86°, forms long plates or prisms, and is hydrolysed by potassium hydroxide with formation of the *potassium* salt, which crystallises with $1H_2O$.   On the addition of bromine to a solution of γ-anisoyl-β-phenylbutyric acid in chloroform, two isomeric γ-*bromo*-derivatives,

$$OMe \cdot C_6H_4 \cdot CO \cdot CHBr \cdot CHPh \cdot CH_2 \cdot CO_2H,$$
are obtained with m. p. 144° (decomp.) and 119° respectively, which both behave in the same way when treated with sodium carbonate, yielding *γ-anisoyl-β-phenyl-γ-butyrolactone*,

$$OMe \cdot C_6H_4 \cdot CO \cdot CH {<}^{CHPh}_{O-CO}{>} CH_2,$$
m. p. 109°, which forms large, six-sided prisms.   The methyl ester also yields two γ-*bromo*-derivatives, m. p. 84° and 122°.   E. G.

A New Oxide of Carbon, $C_{12}O_9$. HANS MEYER and KARL STEINER (*Ber.*, 1913, **46**, 813—815).—When mellitic acid is subjected to the action of dehydrating agents, either it remains unchanged or, by more drastic treatment, it is converted into the anhydride of pyromellitic acid.   As intermediate product, an anhydrocarboxylic *acid* (annexed formula) appears to be formed.   This substance can be isolated in the pure state by prolonged boiling of mellitic acid with thionyl chloride or by heating these substances at 160° during several hours.   It forms a white, crystalline powder, which unites with the calculated quantity of water to form mellitic acid, and which, when strongly heated, yields pyromellitic anhydride and carbonised products.
The *oxide* [*mellitic anhydride*] (annexed formula) is obtained when mellitic acid is boiled under reflux with much benzoyl chloride during six hours.   It separates from boiling benzoyl chloride in colourless crystals, which are perfectly stable and non-hygroscopic.   It is practically insoluble in cold water, but unites with warm water to form mellitic acid.   It gives characteristic colorations with various solvents of high b. p.; thus with naphthalene, retene, phenanthrene, and fluorene it yields rose-red to bluish-red solutions, and with nitrobenzene a bluish green solution.   It darkens when heated above 320°.   H. W.
Constituents of Essential Oils. [Degradation of the Diketone, $C_{13}H_{20}O_2$, Obtained from Selinene.] FRIEDRICH W. SEMMLER and FELIX RISSE (*Ber.*, 1913, 46, 599—603. Compare this vol., i, 66, 188).—The diketone, $C_{13}H_{20}O_2$, obtained by the oxidation of natural selinene and also the diketo-monocarboxylic acid, obtained by the action of ozone on ortho(α)selinene, have been further oxidised, whereby a tribasic acid, $\begin{matrix} CH_2-CH_2-CH\cdot CH(CO_2H)\cdot CH_2\cdot CO_2H \\ CHMe\cdot CH_2\cdot CH\cdot CO_2H \end{matrix}$, has been obtained.

The diketone was most advantageously oxidised by a cold solution of bromine in aqueous sodium hydroxide. The *acid*, $C_{12}H_{18}O_6$, so obtained was purified by solution in alcohol and addition of chloroform, when the precipitated product was found to contain chloroform (about one mol. of chloroform to two mols. of acid), which could only be completely removed by heating it in a vacuum at the temperature of boiling xylene. The pure acid had m. p. 188°. Its tribasic nature was shown by converting it into the methyl *ester*, $C_{15}H_{24}O_6$, b. p. 200—205°, D^{20} 1·140, n_D 1·47948, $\alpha_D - 27°48'$, by the action of methyl iodide on the *silver* salt. The acid could be recovered unchanged after saponification of the ester.

The same acid was obtained when the diketo-monocarboxylic acid, $C_{14}H_{22}O_4$, was oxidised by bromine in alkaline solution or by nitric acid.　　　　　　　　　　　　　　　　　　　　　　　　H. W.

Studies in the *cyclo*Pentadiene Series. III. Certain Derivatives of 5-Nitro-2 : 3-dibenzoyl-$\Delta^{1,3}$-*cyclo*pentadiene. WILLIAM J. HALE and LAMBERT THORP (*J. Amer. Chem. Soc.*, 1913, 35, 262—272. Compare A., 1912, i, 566; this vol., i, 184).—In the earlier papers, it has been shown that the formation of a *cyclo*-pentadiene ring by the condensation of a 1 : 3-dialdehyde with diphenacyl proceeds more slowly than with acetonylacetone. A study has now been made of the behaviour of pp'-dimethyl-, pp'-dibromo-, and p-bromo-diphenacyl. The results show that the effect of methyl groups in the phenyl rings of diphenacyl is to retard the activity of the methylene groups of this ketone, whilst the presence of bromine atoms increases their activity.

By the condensation of pp'-dimethyldiphenacyl (Limpricht, A., 1900, i, 600) with sodium nitromalonaldehyde, 5-*nitro*-2 : 3-*di-p-toluoyl*-$\Delta^{1,3}$-*cyclo*pentadiene, $NO_2\cdot CH \begin{matrix} CH:C\cdot CO\cdot C_6H_4Me \\ CH:C\cdot CO\cdot C_6H_4Me \end{matrix}$, was obtained in a yield of about 75% of the theoretical; it crystallises in yellow prisms, and decomposes at 243—244°. The *silver* salt decomposes at about 200°, and the *monoxime* at 150—151°.

Ethyl p-bromophenacylbenzoylacetate,
$$\cdot C_6H_4Br\cdot CO\cdot CH_2\cdot CHBz\cdot CO_2Et,$$
m. p. 81°, obtained in 75% of the calculated yield by the condensation of p-bromophenacyl bromide with the sodium derivative of ethyl benzoylacetate, forms colourless needles, and when boiled with dilute potassium hydroxide, is converted into p-*bromodiphenacyl*,
$$CH_2Bz\cdot CH_2\cdot CO\cdot C_6H_4Br,$$

m. p. 116°, which crystallises in white plates with a pearly lustre. The yield of the latter compound amounted to 45% of the theoretical. 5-*Nitro-3-benzoyl-2-p-bromobenzoyl*-Δ¹ ˙-*cyclopentadiene*,

$$NO_2 \cdot CH \Big\langle {}^{CH:C \cdot CO \cdot C_6H_4Br}_{CH:C \cdot CO \cdot C_6H_5} ,$$
was obtained in a yield of about 75% of the calculated by the condensation of *p*-bromodiphenacyl with nitromalonaldehyde; it forms small, yellow prisms and decomposes at 240—241°.

The *sodium* derivative of *ethyl* p-*bromobenzoylacetoacetate* was prepared by Claisen's method. When the ester itself is warmed with aqueous ammonia, *ethyl* p-*bromobenzoylacetate*,

$$C_6H_4Br \cdot CO \cdot CH_2 \cdot CO_2Et,$$
is obtained as a pale yellow, oily liquid which cannot be distilled without decomposition even under 5 mm. pressure. Its sodium derivative condenses with *p* bromophenacyl bromide to form *ethyl* p-*bromobenzoyl-p-bromophenacylacetate*, $C_6H_4Br \cdot CO \cdot CH_2 \cdot CH(CO \cdot C_6H_4Br) \cdot CO_2Et$, m. p. 75°, which crystallises in small, colourless prisms; a 60% yield of the theoretical was obtained. When this ester is boiled with dilute potassium hydroxide, it gives 30% of the calculated yield of *pp'*-dibromodiphenacyl, $C_6H_4Br \cdot CO \cdot CH_2 \cdot CH_2 \cdot CO \cdot C_6H_4Br$, m. p. 182°, which forms lustrous, colourless plates, and condenses with nitromalonaldehyde with production of 5-*nitro*-2 : 3-*di*-p bromobenzoyl-Δ¹ ˙-*cyclopentadiene*,

$$NO_2 \cdot CH \Big\langle {}^{CH:C \cdot CO \cdot C_6H_4Br}_{CH:C \cdot CO \cdot C_6H_4Br'}$$
which forms yellow crystals and decomposes at 230—232°.   E. G.

Action of Hydrochloric and Hydrobromic Acids on 2 : 4-Dimethylquinol [2 : 4-Dimethyl-Δ² ⁵-*cyclo*hexadiene-4-ol-1-one]. EUGEN BAMBERGER and EMIL REBER (*Ber.*, 1913, 46, 787—813).—It has been previously shown (Bamberger and Brady, A., 1901, i, 142) that aqueous sulphuric acid converts 2 : 4-dimethyl-Δ³ ⁵-*cyclo*hexadiene-4-ol-1-one into *p*-xyloquinol. Hydrochloric acid, in aqueous solution, transforms it mainly into 5-*chloro*-m-4-*xylenol* and 6-*chloro*-m-4-*xylenol*, whilst, in anhydrous glacial acetic acid solution, the latter isomeride is alone obtained. The actions are probably represented by the scheme:
Under similar conditions, hydrobromic acid forms mainly 5-bromo-

m-4-xylenol and 6-bromo-*m*-4-xylenol. The identity of the products was also synthetically established. In the light of the present work, a modified interpretation is given to the observation of Bamberger, Büsdorf, and Szolayski (A., 1899, i, 341) that *p*-nitrosotoluene is converted by hydrochloric and hydrobromic acids into 3-chloro-*p*-cresol, in that hemiquinols are now assumed to be formed as intermediate products.

An improved method for the preparation of 1 : 3-dimethylphenyl-hydroxylamine is described (compare Bamberger and Brady, *loc. cit.*).

2 : 4-Dimethyl-Δ^2 ^{5}-*cyclo*hexadiene-4-ol-1-one was heated during one hour at 100° with fuming hydrochloric acid, the mixture diluted with water, and extracted with ether. After drying the ethereal extract, the ether was removed, the residue was allowed to solidify as completely as possible, the solid portions filtered off, and the liquid part submitted to fractional distillation with steam. The following substances were obtained : 5-chloro-*m*-4-xylenol, b. p. 86·5—87°/9 mm. (*phenylurethane*, m. p. 129—130°; p-*nitrobenzoate*, white needles, m. p. 94—95°); 6-chloro *m*-4-xylenol, white, silky needles, m. p. 90—91° (*benzoate*, glassy prisms, m. p. 84·5—85·5°); a *substance*, m. p. 169—170°, possibly chlorodixylenol; a *substance*, m. p. 190°, reddish-yellow needles, possibly chloro-*p*-xyloquinol; traces of *p*-xyloquinol and resin. In a second experiment, dixylenol was obtained in addition to *p*-xyloquinol and *p*-xyloquinone.

5-Chloro-*m*-4-xylenol was prepared by pouring a diazotised solution of 5-amino-*m*-4-xylenol into boiling cuprous chloride solution, and had b. p. 100—101°/17 mm. The phenylurethane and *p*-nitrobenzoate obtained from it were identical with those obtained above.

The synthesis of 6-chloro-*m*-4-xylenol was effected in the following manner : 6-nitro-*m*-4-xylidine was diazotised and treated with cuprous chloride solution, whereby 4-chloro-6-nitro-*m*-xylene, m. p. 42°, was obtained (compare Ahrens, *Annalen*, 1892, **271**, 17). The latter was reduced by tin and hydrochloric acid to 6-chloro-*m*-4-xylidine, leaflets, m. p. 98·5—99°, which, according to Bamberger and Cadgène (*Dissert.*, 1903), is also formed by the action of concentrated hydrochloric acid on *as*-*m*-xylylhydroxylamine. The *hydrochloride, sulphate,* and *oxalate* were also prepared. The *acetyl* derivative forms silky needles, m. p. 158·5°. *Phenyl-4-chloro*-m-*xylylcarbamide*, $C_6H_2Me_2Cl\cdot NH\cdot CO\cdot NHPh$, white, silky needles, has m. p. 217—218° after previous softening. It immediately re-solidifies, melting again at 255° (decomp.). The corresponding *thiocarbamide* has m. p. 140—140·5° when rapidly heated. When slowly heated it melts at a lower temperature. Diazotisation and subsequent boiling of the aqueous solution converts 6-chloro-*m*-4-xylidine into 6-chloro-*m*-4-xylenol, which is identical with the substance described above.

The action of hydrogen chloride dissolved in glacial acetic acid on 2 : 4 dimethyl*cyclo*hexadienolone gave 6-chloro-*m*-4-xylenol, chloro-*p*-xyloquinol, traces of an oily chloroxylenol, resin, and, possibly, *p*-xyloquinol.

2 : 4-Dimethyl*cyclo*hexadienolone, when heated on the water-bath with aqueous hydrobromic acid, b. p. 122—123°, yielded 5-bromo-*m*-4-xylenol (which possibly contained small quantities of 6-bromo-*m*-4-

xylenol, *as*-m-xylenol, and *p*-xyloquinone), dixylenol, *p*-xyloquinol (or *p*-xyloquinone), and an amorphous *acid*.

To determine the constitution of the above bromoxylenol, it was treated with bromine in glacial acetic acid solution. The *product* obtained, long, white needles, m. p. 179·5—180°, had the same m. p. as 2 : 3 : 6-tribromo-*p*-5-xylenol (obtained by bromination of *p*-xylenol) and 2 : 5 : 6-tribromo-*m* : 4-xylenol (obtained by brominating *m*-xylenol), whilst mixtures of any of the three compounds showed no noticeable depression of m. p. When acted on by benzoyl chloride, however, the *benzoates*, m. p. 151—152°, obtained from 2 : 5 : 6-tribromo-*m* : 4-xylenol, and from the product of the successive action of hydrobromic acid and bromine on 2 : 4-dimethyl*cyclo*hexadienolone, proved to be identical, whereas 2 : 3 : 6-*tribromo*-p-*xylenyl*-5-*benzoate* had m. p. 128—129°; hence, the above monobromoxylenol is probably 5-bromo-*m*-4-xylenol. The *benzoate* and *phenylurethane* of the latter were prepared.

The direct synthesis of 5-bromo *m*-4-xylenol (compare Stoermer and Göhl, A., 1903, i, 848; Orton, Coates, and Burdett, T., 1907, 91, 53) was effected by the action of cuprous bromide solution on a diazotised solution of 5-amino-*m*-4-xylenol hydrobromide. It had b. p. 121 5—122·5°/37 mm., and yielded a benzoate, m. p. 49—50·5°, and a phenylurethane, m. p. 136·5—137°, after previous softening, which proved to be identical with the above-mentioned products.

2 : 4-Dimethyl*cyclo*hexadienolone, when treated with hydrogen bromide in anhydrous glacial acetic acid solution, gave 6-bromo-*m*-4-xylenol, m. p. 76—76·5°, 5-bromo-*m*-4-xylenol, probably *p*-xyloquinone, possibly crude monobromo-*p*-xyloquinol and resin. The constitution of the solid bromoxylenol follows from its identity with the product obtained from 6-nitro-*m*-4-xylidine by conversion of the latter into 4-bromo-6-nitro-*m*-xylene, reduction of this substance by iron filings and acetic acid to 6-bromo-*m*-4-xylidine and diazotisation of the latter substance (compare Noelting, Braun, and Thesmar, A., 1901, i, 589).   H. W.

Preparation of Derivatives of *p*-Benzoquinone. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 253091)—When the dinaphthylamino-*p*-benzoquinones (and their derivatives), obtained by the action of *p*-benzoquinone on α- and β-naphthylamines, are heated with reagents having a high boiling point, they furnish highly coloured compounds, which after sulphonation are of technical importance.

Di - 2 - naphthylaminodichloro-*p*-benzoquinone, $C_6O_2Cl_2(NH \cdot C_{10}H_7)_2$ (obtained from tetrachloro-*p*-benzoquinone and β-naphthylamine), when boiled during three hours with nitrobenzene furnishes the *compound*, $C_{26}H_{15}O_2NCl$, glistening, green crystals, m. p. above 300°, whilst the isomeric *compound* from α-naphthylamine has similar properties.

The *compound*, $C_{52}H_{29}O_4N_4Cl$, is obtained from di-2-naphthylamino-chloro-*p*-benzoquinone, whilst that from di-2-naphthylamino-*p*-benzoquinone, $C_6H_2O_2(NH \cdot C_{10}H_7)_2$, forms a brownish-yellow powder.   F. M. G. M.

Preparation of Chloroanthraquinones. BADISCHE ANILIN-& SODA-FABRIK (D.R.-P. 254450. Compare A., 1908, i, 994, and this vol., i, 49, 61).—The preparation of α-chloroanthraquinones by the replacement of a nitro-group by chlorine has been described (*loc. cit.*), and the reaction has now been extended to the β-nitroanthraquinones.

When a suspension of 2-nitro-3-methylanthraquinone in trichlorobenzene is treated with chlorine at 150—180°, it gives rise to a yellow precipitate consisting of a mixture of ω-2-tetrachloro- and ω-2-trichloro-3-methylanthraquinones, which by the action of hot concentrated sulphuric acid, followed by treatment with sodium carbonate, furnishes a readily separable mixture of 2-*chloroanthraquinone*-3-*carboxylic acid*, m. p. 280°, and of 2-*chloroanthraquinone*-3-*aldehyde*, m. p. 229°, whilst the technical mixture of 1 : 6- and 1 : 7-dinitroanthraquinones give rise on similar treatment to 1 : 6-*dichloroanthraquinone*, $C_{14}H_6O_2Cl_2$, m. p. 202—204°.　　　F. M. G. M.

Preparation of 1-Halogen-2-aminoanthraquinones. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 253683. Compare A., 1904, i, 256).—When 2-aminoanthraquinone-3-sulphonic acid is treated with a halogen (1 mol.) it readily yields a 1-halogen-2-aminoanthraquinone-3-sulphonic acid, which by heating with 80% sulphuric acid is converted into the corresponding 1-halogen-2-aminoanthraquinone.

Sodium 1-*chloro*-2-*aminoanthraquinone*-3-*sulphonate* forms orange-red crystals; 1-*chloro*-2-*aminoanthraquinone*, yellow needles, m. p. 228—229°; *sodium* 1-*bromo*-2-*aminoanthraquinone*-3-*sulphonate*, orange-red leaflets, and 1-*bromo*-2-*aminoanthraquinone*, glistening, brownish-red leaflets, m. p. 305°, which on further bromination yields 1 : 3-dibromo-2-aminoanthraquinone.　　　F. M. G. M.

Preparation of Nitro-*p*-acyldiaminoanthraquinone. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D. R.-P. 254185).—Nitro-*p*-acyldiaminoanthraquinones are readily obtained by the action of nitric acid (D 1·5) at temperatures not exceeding 25° on diacyl-1 : 4-diaminoanthraquinones, the nitro-group entering the ortho-position with respect to an amino-group.

2-*Nitro*-1 : 4-*diacetyldiaminoanthraquinone* forms yellowish-brown needles, m. p. 237° (decomp.), and on hydrolysis furnishes 2-*nitro*-1 : 4-diaminoanthraquinone as a blue, crystalline powder.

2-*Nitro*-1 : 4-*diaminoanthraquinoneurethane*, orange-red needles, m. p. 230—232°, is obtained in a similar manner from 1 : 4-diaminoanthraquinoneurethane.　　　F. M. G. M.

Preparation of Dianthraquinonylthio-ethers. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254561).—Dianthraquinonyl thio-ethers are readily prepared by heating anthraquinone mercaptans.

ββ-*Dianthraquinonyl thio-ether*, yellow needles, is thus obtained from anthraquinone β-mercaptan; the isomeric αα-*dianthraquinonyl thio-ether* is a reddish-brown, crystalline powder, whilst αβ-*dianthraquinonyl thio-ether* is prepared by heating together molecular proportions of α- and β-anthraquinone mercaptans.

6-Chloro-1-benzoylaminoanthraquinone when treated with sodium

sulphide furnishes 1-benzoylaminoanthraquinone 6-mercaptan ; this, when heated, gives rise to 1 : 1'-*dibenzoyldiamino*-6 : 6'-*dianthraquinonyl thio-ether*, which crystallises from nitrobenzene in yellow needles.

F. M. G. M.

Anthraflavone-G. EDUARD HEPP, RUDOLF UHLENHUTH, and FRITZ ROMER (*Ber.*, 1913, 46, 709—712).—To the above dye (D.R.-P.199756) has been attributed the structure 1 : 2 : 5 : 6-diphthaloylanthracene (Bohn, A., 1910, i, 405). In its preparation by the action of calcium hydroxide on ω-dichloromethylanthraquinone, the occurrence of large quantities of anthraquinone-2-carboxylic acid as by-product suggests that the first product of the reaction is anthraquinone-2-aldehyde, which then undergoes change into the corresponding acid and alcohol, the latter of which then condenses to anthraflavone. According to this view the dye must be diphthaloylstilbene, and its formation by the action of lead oxide on 2-methylanthraquinone and its derivatives would be analogous to the well-known formation of stilbene from toluene. A convincing proof of the untenability of the older view with regard to the structure is given by the preparation of the dye in better yields than hitherto, from ω-dibromo-2-methylanthraquinone by the action of copper powder or sodium iodide on solutions in nitrobenzene and acetone respectively.

The last method of preparation can be extended to substituted anthraflavones. 1-*Chloro*-2-*methylanthraquinone*, yellow needles, m. p. 171°, obtained from 2-methylanthraquinone-1-sulphonic acid by heating with potassium chlorate and hydrochloric acid, when treated with bromine in nitrobenzene solution is converted into 1-*chloro*-ω-*dibromomethylanthraquinone*, yellow leaflets, m. p. 176° ; the action of sodium iodide on the acetone solution of this substance produces 1 : 1'-*dichloroanthraflavone* (2 : 2'-dichloro-3 : 4 : 3' : 4'-diphthaloylstilbene), a yellow, crystalline powder.

The new formula for this class of dye also gives a satisfactory explanation of other properties, such as the quantitative conversion into the corresponding anthraquinonecarboxylic acids.   D. F. T.

2-Methylanthraquinone. FRITZ ULLMANN AND KARL LUDWIG KLINGENBERG (*Ber.*, 1913, 46, 712—725).—The authors have found that for the preparation of anthraquinone-2-aldehyde in larger quantities, the best method is by the intermediate formation of ω-dibromomethylanthraquinone. The stilbene structure for anthraflavone (see Hepp, Uhlenhuth, and Römer, preceding abstract) is confirmed.

Anthraquinone-2-*aldehyde* can be obtained by the gradual addition of a mixture of chromic acid and acetic acid to a suspension of 2-methylanthraquinone in acetic anhydride containing a little sulphuric acid, and also by heating ω-dibromomethylanthraquinone (prepared by the action of bromine on the methylanthraquinone in nitrobenzene solution at 150—160°) with concentrated sulphuric acid at 125—130°. The aldehyde forms pale yellow leaflets or needles, m. p. 188—189° (corr.) ; *phenylhydrazone*, reddish-violet needles, m. p. 242°(corr.); *oxime*, straw-yellow needles, m. p. 238—239° ; *semicarbazone*, yellow needles, m. p.

397° (corr.); *azine*, yellow needles, m. p. 410°: *sodium disulphite* compound, colourless crystals.

When a suspension of anthraquinone-2-aldehyde in dimethylaniline with zinc chloride is heated on a water-bath, condensation occurs; the same substance, 2-*anthraquinonyltetramethyldiaminodiphenylmethane*, is obtained when ω-dibromomethylanthraquinone is warmed with dimethylaniline and zinc chloride; it crystallises in red needles, m. p. 240—241° (corr), and can be oxidised to a green colouring matter.

The reaction between ω-dibromomethylanthraquinone and dimethylamine or diethylamine follows a different course at the b. p. of the mixture, the product being the same as that from the action of copper powder on dibromomethylanthraquinone, namely, anthraflavone,

$$C_6H_4{<}^{CO}_{CO}{>}C_6H_4 \cdot CH{:}CH \cdot C_6H_4{<}^{CO}_{CO}{>}C_6H_4$$
(diphthaloylstilbene, dianthraquinonylethylene), identical with the known dye; it is oxidised by sodium dichromate and nitric acid to anthraquinone-2-carboxylic acid, m. p. 285°, and when boiled with bromine in nitrobenzene solution yields the *dibromide*, m. p. above 400°; this on boiling with diethylaniline regenerates the anthraflavone.

If ω-dibromomethylanthraquinone is heated at 240—250°, hydrogen bromide is eliminated and 2 : 2′-*dianthraquinonylacetylene dibromide*, yellow needles, m. p. 360°, is obtained; when heated with diethylaniline or alkali phenoxide, the last substance is converted into 2 : 2′-*dianthraquinonylacetylene (diphthaloyltolane)*, yellow leaflets, m. p. 350—353°, which unites with bromine to yield the dibromide, and is oxidised by chromic acid in the presence of nitric acid to anthraquinone-2-carboxylic acid; it can also be reduced by hyposulphite to a red vat, which dyes cotton yellow.
                                                                                                D. F. T.

Action of Carbon Dioxide on the Magnesium Compound of Fenchyl Chloride.

GUSTAV KOMPPA and S. V. HINTIKKA (*Ber.*, 1913, **46**, 645—648).—Fenchyl chloride reacts with magnesium in the course of a week, and when carbon dioxide is passed through the product, the reaction leads to as complicated a mixture as Houben experienced in the case of pinene hydrochloride (A., 1893, i, 42). When the ethereal extract is shaken with sodium carbonate it gives, starting from inactive fenchyl chloride, a clear aqueous solution containing hydrofenchenecarboxylic acid and an emulsion from which a small quantity of *hydrodifenchenecarboxylic acid*,

$$C_{10}H_{17} \cdot C_{10}H_{16} \cdot CO_2H,$$
may be isolated in the form of long, glistening needles, m. p. 106°, whilst the predominating, neutral portion, on fractionation, yields an almost inactive *hydrodifenchene*, $C_{20}H_{34}$, as a glycerol-like liquid, b. p. 155—157°/10 mm., D_4^{17} 0·9564, n_D 1·50928, and also inactive fenchene, and probably some fenchyl alcohol.

Active fenchyl chloride, a_D^{18} − 6°0′, however, gives a better yield of *hydrofenchenecarboxylic acid*, $C_{10}H_{17} \cdot CO_2H$, in the form of a white, very soluble, inactive mass, b. p. 140—142°/20 mm., m. p. 52—53°, which yields an *amide*, m. p. 107°, and an *anilide*, m. p. 105—106°. On the other hand, no hydrodifenchenecarboxylic acid is obtained, and less neutral substances are formed, from which active *hydrodifenchene*,

b. p. 155—156°/10 mm., D_1^{17} 0 9652, n_D 1·51299, a_D^{18} +5°30′, and an active fenchene, a_D^{20} +4°17′, have been isolated.   J. C. W.

Preparation of Esters of Dibromo-β-phenylpropionic Acid. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254666. Compare this vol., i, 63).—*Fenchyl di bromo-β-phenylpropionate*, colourless, tasteless prisms, m. p. 105°, and of therapeutic value, is readily prepared by heating together fenchyl alcohol and dibromo-β-phenylpropionyl chloride in benzene solution.   F. M. G. M.

Preparation of a Fenchyl Ester. CHEMISCHE FABRIK VON KERESZTY, WOLF & CIE (D.R.-P. 253756).—*Fenchyl salicylate*, m. p. 51°, is of therapeutic value, and can be prepared by known methods from fenchyl alcohol and salicylic acid (or methyl salicylate).
    F. M. G. M.

The Constitution of Camphene. EDUARD BUCHNER and WILHELM WEIGAND (*Ber.*, 1913, 46, 759—768).—Of the three suggested formulæ for camphene :

$$
\begin{array}{ccc}
\text{CH}_2\cdot\text{CH—CMe}_2 & \text{CH}_2\cdot\text{CH—CMe}_2 & \text{CH}_2\text{——CH} \\
| & | \quad | & | \\
\text{CH}_2 & \text{CH}_2 \ \text{CH} & \text{CH}\cdot\text{CMe}_2\text{—}\ \ \text{CMe} \\
| & | \quad \| & | \\
\text{CH}_2\cdot\text{CH—C:CH}_2 & \text{CH}_2\cdot\text{CH—CH} & \text{CH}_2\text{——CH} \\
\text{(I.)} & \text{(II.)} & \text{(III).}
\end{array}
$$
the first (Wagner's formula) has been received with most favour (compare Semmler, A., 1909, i, 170; Harries and Palmén, A., 1910, i, 497; Komppa, A., 1911, i, 388), and has received additional support from molecular refractivity considerations (von Auwers, A., 1912, ii, 214). A final decision on purely chemical grounds appears to be possible by the application of ethyl diazoacetate.

It has already been shown that benzene and ethyl diazoacetate couple with loss of nitrogen to form ethyl norcaradienecarboxylate,

$$\begin{array}{c}\text{CH:CH·CH} \\ \text{CH:CH·CH} \end{array}\!\!>\text{CH·CO}_2\text{H},$$

which after hydrolysis can be oxidised to *cyclo*propane-*trans*-1 : 2 : 3-tricarboxylic acid (Braren and Buchner, A., 1901, i, 385). If this reaction could be applied generally, a substance of formula 1 should yield 2 : 2-dimethylnor-
$$
\begin{array}{c}
\text{CH}_2\cdot\text{CH—CMe}_2 \\
| \\
\text{CH}_2 \\
| \\
\text{CH}_2\cdot\text{CH-C—CH}_2 \\
\diagdown\diagup \\
\text{CH·CO}_2\text{H} \\
\text{(IV.)}
\end{array}
$$

camphane-3-*spirocyclo*propanecarboxylic acid (formula IV annexed), which might be oxidised to *cyclo*propane-1 : 1 : 2-tricarboxylic acid ; a substance of formula II would give finally *cyclo*propane-1 : 2 : 3-tricarboxylic acid, whilst a substance of formula III would not react with ethyl diazoacetate. Experiment gives results in entire accord with the first of these possibilities, thus providing apparently final evidence in favour of formula I.

It is interesting to note that the condensation product of ethyl diazoacetate and camphene is a *spirane* molecule with three-ring systems, this view being supported by determinations of the molecular refraction and dispersion.

The camphene used was mainly prepared from bornyl chloride by the action of aniline (Ullmann and Schmid, A., 1911, i, 70); the same condensation product was always obtained. For the condensation, a mixture of 5 grams of camphene with 5 grams of methyl diazoacetate was gradually added to 30 grams of camphene (m. p. 44—45°; b. p. 156—157°/745 mm.; $[a]_D^{15} + 62.59°$) containing 1 gram of copper powder as catalyst, at 160—165°. A practically theoretical volume of nitrogen is liberated, and *methyl* 2 : 2-*dimethylnorcamphane*-3-spirocyclo-*propanecarboxylate* is obtained as a colourless oil, b. p. 126°/14 mm., $[a]_D^{19.5} + 6.79°$, $D_4^{18.5}$ 1.0268, $n_D^{18.3}$ 1.48567, with an odour resembling camphene; in suspension in sodium carbonate solution it is stable towards potassium permanganate. The corresponding *ethyl* ester, obtained by the application of ethyl diazoacetate, has b. p. 128—136°/14 mm. The esters can be hydrolysed to the corresponding acid (formula IV) by alcoholic potassium hydroxide, and the product was purified by conversion into the acid *chloride*, which is changed by concentrated aqueous ammonia into the *amide*, colourless leaflets, m. p. 124°; 2 : 2-*dimethylnorcamphane*-3-spirocyclopropanecarboxylic *acid*, obtained by hydrolysis of this, forms colourless needles, m. p. 108°; the *calcium*, *barium*, *lead*, and *silver* salts were obtained by precipitation from an aqueous solution of the *ammonium* salt. When an intimate mixture of the amide with sodium hypobromite solution is warmed on a water-bath, 2 : 2-*dimethylnorcamphane*-3-spiroaminocyclopropane is produced as an unpleasant smelling oil; *hydrochloride*, colourless leaflets, m. p. 253° (decomp.); yellow *aurichloride*, m. p. 160° (decomp.); *platinichloride*, golden prisms decomposing at 237°; yellow *picrate*, m. p. 201°.

If the methyl ester obtained by the condensation of camphene and methyl diazoacetate is treated in alcoholic solution with sodium, it becomes reduced to 2 : 2-*dimethylnorcamphane*-3-spirocyclopropane-*methylol*, $C_{11}H_{17}\cdot CH_2\cdot OH$, a colourless, viscous liquid, b. p. 129°/12 mm., $a_D^{20} + 26.79°$, D_4^{19} 0.9972, n_D^{19} 1.50205, with an odour resembling that of camphene; *phenylurethane*, needles, m. p. 234°.

The oxidation of 2 : 2-dimethylnorcamphane-3-*spirocyclo*propane-carboxylic acid was effected in dilute sulphuric acid by potassium permanganate, the last substance is added as required, and the process occupies many hours; the oxidation tends to proceed too far, and only a relatively small quantity of *cyclo*propane-1 : 1 : 2-tricarboxylic acid was obtained, which on heating lost carbon dioxide with formation of a mixture of *cyclo*propane-1 : 2-*cis*dicarboxylic acid and the corresponding anhydride; acetyl chloride dehydrated this to the pure anhydride, which was definitely recognisable.   D. F. T.

The Constituents of Ethereal Oils. High-boiling Camphor Oil. FRIEDRICH W. SEMMLER and IRENE ROSENBERG (*Ber.*, 1913, **46**, 768—774).—A more careful investigation of the constituents of the blue-coloured, high-boiling camphor oil (compare Schimmel & Co., A , 1909, i, 816).

The oil was separated by distillation into three fractions, b. p. 130—150°/10 mm., 150—170°/10 mm., and 170—190°/10 mm.

The first fraction contained limene and a little cadinene, which were

identified by their hydrogen chloride additive compounds; limene trihydrochloride, m. p. 79°, has before solidification the following properties. b. p. 177—189°/8 mm., D^{20} 1·0370, n_D 1·50152, $[a]_D \pm 0°$. The presence of three ethylenic linkings in limene was proved by reduction in acetic acid with hydrogen and platinum black to *hexahydrolimene*, an optically inactive liquid, b. p. 123—125°, D^{20} 0·8244, n_D 1·45423. This fraction also contained a sesquiterpene, $C_{15}H_{24}$, b. p. 129—133°, D^{20} 0·9015, n_D 1·50058, $[a]_D + 3°$, for which the name *sesquicamphene* is suggested; although the data suggest a bicyclic diolefinic substance, no solid hydrogen chloride additive compound was obtainable.

The second fraction had as almost sole constituent a sesquiterpene alcohol, $C_{15}H_{26}O$, b. p. 159—162°, D 0·95413, for which the name *sesquicamphenol* is suggested; it was purified by conversion into the sodium alcoholate and regeneration by treatment with water; by heating with potassium hydrogen sulphate at 180° for two hours a molecule of water is eliminated with formation of a *hydrocarbon*, b. p. 125—130°, D^{20} 0·9138, n_D 1·50895, $[a]_D + 50°$, which is probably a reduced naphthalene derivative; no solid hydrochloride was obtainable.

The least volatile fraction consisted chiefly of hydrocarbons, from which small quantities of oxygen compounds were removed by heating with sodium; the purified product, b. p. 180—190°/11 mm., D^{20} 0·9276, n_D 1·51986, $[a]_D + 1°$, is a diterpene, $C_{20}H_{32}$, a class of substance generally absent from ethereal oils. If this crude product is treated in ethereal solution with hydrogen chloride, a *tetrahydrochloride*, thin tablets, m. p. 129—131°, is obtained, from which the hydrocarbon can be regenerated in a purer condition by treating successively with a mixture of sodium acetate and acetic acid and then alcoholic potassium hydroxide; it then has b. p. 177—178°/6 mm., D^{20} 0·8870, n_D 1·50339, $[a]_D \pm 0°$. This monocyclic hydrocarbon, for which the name *a-camphorene* is proposed, is reduced by hydrogen and platinum black to *octahydro-a-camphorene*, $C_{20}H_{40}$, b. p. 174—176°/9 mm., D^{20} 0·8526, n_D 1·46470, $[a]_D \pm 0°$. From the oily residue obtained in the preparation of the tetrahydrochloride, could be regenerated by alcoholic potassium hydroxide a bicyclic isomeride, *β-camphorene*, $C_{20}H_{32}$, b. p. 170—180°/10 mm., D^{20} 0·930, n_D 1·518°, $[a]_D \pm 0°$, which gives no solid additive compound with hydrogen chloride.

The blue colour of all high-boiling fractions of camphor oils is due to such small traces of a coloured substance that no particulars of its composition could be determined.   D. F. T.

Caoutchouc and Guttapercha Resins. G. H. HILLEN (*Arch. Pharm.*, 1913, **251**, 94—121).—Proximate analyses have been made of the resinous portions of various kinds of caoutchouc and allied products.

The resinous portion of "pontianac," "bresk" or "dead Borneo," an inferior "rubber" obtained from the latex of *Dyera costulata*, Hook, was found to contain lupeol acetate, α-amyrin acetate, β-amyrin acetate, and a resen (compare Sack and Tollens, A., 1904, i, 1011; Cohen, A., 1907, i, 211, 230). The formula $C_{26}H_{42}O$ is suggested for lupeol.

The caoutchouc (Ceara rubber) of *Manihot glaziovii*, prepared by the

Lewa process in German East Africa, contains 7% of resin. composed of *iso*cholesterol acetate, a soft resin, and a green, amorphous substance.

Guayule caoutchouc contains 16% of resin, composed of soft resinous material, probably formed by the oxidation of the essential oil contained in the plant, which contains no substances giving the phytosterol reactions (compare Alexander, A., 1911, i, 897).

"Malabuwai guttapercha" from *Alstonia grandifolia*, Miq., contains α-amyrin acetate, β-amyrin acetate, an oily substance, and traces of a yellow resen.

The resin of *Palaquium Gutta* from German New Guinea contains lupeol cinnamate, an oily substance, and a small quantity of a resen.

A table giving the percentages of resin, the appearance of the resins under the microscope, and their reactions with the usual phytosterol reagents for a number of commercial caoutchoucs is provided.

The colour reactions of most of the substances referred to in the paper with phytosterol reagents are tabulated.　　　　T. A. H.

The Viscous Transformation of Caoutchouc. A. VON ROSSEM (*Zeitsch. Chem. Ind. Kolloide*, 1913, **12**, 78—83).—According to Gorter (*Mededeelingen over Rubber*, 1911) the transformation of ordinary caoutchouc into the viscous, glue-like modification under the influence of heat, light, and certain chemical reagents is due to depolymerisation. It is suggested that normal polymerised caoutchouc is under ordinary conditions metastable, and that the formation of the viscous variety simply corresponds with the transition from the metastable to the stable form. In support of this view, Gorter describes experiments which show that if a benzene solution of caoutchouc, prepared and kept in the dark, is mixed with a caoutchouc solution which has been exposed to sunlight for some time, the viscosity of the mixed solution gradually diminishes when the solution is protected from the light by means of red glass. In exactly similar circumstances, the viscosity of the original solution was found to remain constant, and the difference in behaviour is supposed to be due to the "inoculation" of the original solution with the stable modification when this solution is mixed with the insolated solution.

To test this theory, measurements of the viscosity of 1% solutions of caoutchouc have been made, with special reference to the influence of light. After exposure to the light from an arc lamp for some hours, the viscosity is found to have diminished, but the subsequent fall is very slow if the solution is kept in the dark, and does not differ from that exhibited by a portion of the original solution which has not been exposed to the arc light. If diffused daylight is allowed access to the solution, the subsequent fall in the viscosity is very much more rapid.

Similar experiments were made with solutions exposed to the light from a Uviol lamp. The results obtained in both series show that there is no after-effect of the light in so far as the viscosity of the solutions is concerned. In some of these experiments the caoutchouc solutions were exposed to the Uviol lamp in glass vessels, whilst in others, quartz vessels were employed. After six and three-quarter

d d 2

hours' exposure, the time of out-flow of a certain volume of solution was found in a particular case to have fallen from 560 to 412 seconds with the glass apparatus, whilst the time required by the solution after exposure in the quartz tube was only 56 seconds. These results indicate that the active rays are the short-waved rays which are absorbed by glass.   H. M. D.

The Hydrohaloids of Artificial and Natural Caout-choucs, and the Caoutchouc-like Substances Regenerated from Them. CARL D. HARRIES (*Ber.*, 1913, **46**, 733—743).— Contrary to the statement of Weber (A., 1900, i, 353), caoutchouc forms additive compounds with hydrogen bromide and hydrogen iodide, as well as with hydrogen chloride. The method followed was to saturate the chloroform solution of the caoutchouc with the gas, and then after several hours to precipitate by alcohol.

Natural caoutchouc unites with two molecules of each acid, forming substances : $C_{10}H_{18}Cl_2$, $C_{10}H_{18}Br_2$, $C_{10}H_{18}I_2$; guttapercha, caoutchouc obtained by the polymerisation of isoprene under the influence of heat and of sodium, and also caoutchouc obtained from dimethylbutadiene, behave in a similar manner, except that the additive compounds of the two former synthetic caoutchoucs with hydrogen iodide, after precipitation, contain only one molecule of hydrogen iodide.

The halogen hydride is only partly removed by treatment with organic bases, but pyridine and piperidine at 125—145° act on the compounds, if necessary in benzene solution, with elimination of the two molecules of hydracid. The products are not identical with natural caoutchouc, but resemble more the synthetic substance obtained by the action of sodium (Harries, A., 1911, i, 798). The elimination of halogen hydride by heating with sodium hydroxide or sodium amide gives a halogen-free caoutchouc, which, however, is apparently different from the natural product and from that obtained by polymeri-sation with sodium. The dihydrochloride of guttapercha, when treated for the elimination of two molecules of hydracid, yields a compound resembling caoutchouc, possibly indicating a conversion of guttapercha into caoutchouc.

From a consideration of the difficulty with which the above new forms of caoutchouc undergo ozonisation, it is tentatively suggested that their molecules include a conjugated pair of ethylenic linkings,

for example, $CHMe\begin{smallmatrix}CH_2 \cdot CH_2 \cdot CH_2 \\ CH:CH——CH\end{smallmatrix}CMe$ and

$$CHMe\begin{smallmatrix}CH_2—CH:CH \\ CH_2 \cdot CH_2 \cdot CH\end{smallmatrix}CMe,$$
whilst the arrangement in natural caoutchouc is

$$CMe\begin{smallmatrix}CH \cdot CH_2—CH_2 \\ CH_2 \cdot CH_2 \cdot CH\end{smallmatrix}CMe.$$
[With EWALD FONROBERT.]—From natural caoutchouc were prepared the dihydrochloride, *dihydrobromide*, and *dihydriodide*; from caoutchouc, obtained by polymerisation on warming, were prepared a *dihydro-chloride*, *dihydrobromide*, and a *hydriodide* ; "sodium polymerised" caoutchouc yielded a *dihydrochloride*, a *hydrobromide*, and a *hydriodide*; "dimethylbutadiene" caoutchouc yielded a *dihydrochloride*, *dihydro-*

bromide, and a *dihydriodide*; guttapercha yielded a *dihydrochloride*, *dihydrobromide*, and a *dihydriodide*. Although affected by hydrofluoric acid no hydrofluoride was obtainable from any of the preceding hydrocarbon substances. The above hydrohaloids are amorphous, sometimes viscous, substances, which undergo decomposition at temperatures between 100° and 200°.

The caoutchouc regenerated from the dihydrochlorides by treatment with pyridine or piperidine at 125—135° resembles "sodium isoprene" caoutchouc in solubility and slow absorption of ozone to produce a diozonide, but yields a relatively stable *dihydrobromide* and *dihydriodide*.

D. F. T.

Theory of Vulcanisation. DAVID SPENCE (*Zeitsch. Chem. Ind. Kolloide*, 1913, **12**, 84—85).—Polemical against Kindscher and Hinrichsen (A., 1912, i, 1007) and Ostwald (A., 1912, i, 706).

H. M. D.

α- and β-Antiarin and on Crystallised Albumin from Antiaris Latex. HEINRICH KILIANI (*Ber.*, 1913, **46**, 667—680. Compare A., 1897, i, 91, and A., 1911, i, 138).—Crystallised rhamnose, m. p. 93—94°, and antiarigenin, m. p. 188°, have been obtained from β-antiarin by means of dilute hydrochloric acid. The α- and β-antiarins only differ in their sugars, and careful analyses lead to the formulæ $C_{27}H_{40}O_{10}, 4H_2O$ and $C_{27}H_{40}O_{10}, 3H_2O$ respectively, whilst antiarigenin receives the formula $C_{21}H_{28}O_5$. The hydrolysis of these glucosides by means of dilute acids is accompanied by the extensive formation of resinous matter, which seems to indicate the presence of a labile aldehyde or ketone group in antiarigenin. The action of the common moulds is quite unavailing, although the glucosides soon disappear from unpreserved antiaris latex, which may, therefore, contain a specific enzyme.

Antiarose could not be obtained crystalline, but the lactone of antiaronic acid, well-defined monoclinic crystals of the epidote type, has been converted into the following derivatives, which differ from those of the known metameric acids: *phenylhydrazone*, long needles, m. p. 143—145°; *quinine* salt, very slender needles, m. p. 180—181°, more soluble in cold water than the *quinine* salt of rhamnonic acid, which forms nodules of silky needles, m. p. 180—182°; *brucine* salt, small, pointed needles with $2H_2O$, m. p. 118—119°; brucine salt of rhamnonic acid, large crystals with $7H_2O$, m. p. 120—126°.

α-Antiarin is considerably attacked by sodium amalgam, and forms an *oxime*, $C_{27}H_{41}O_{10}N, 2H_2O$, m. p. 239—240°, which, however, like the parent substance, is unaffected by aluminium amalgam in the cold. Antiarigenin yields a *semicarbazone*, $C_{22}H_{31}O_5N_3$, which begins to sinter at 225°.

Attempts to oxidise the glucosides with silver oxide or hydrogen peroxide were without result, but the action of chromic acid, nitric acid, or permanganate promises to throw light on their constitution.

"Antiaris residue," the portion of the latex which is insoluble in alcohol, contains a protein which may be extracted to the extent of 6·3% by means of 0·8% acetic acid (compare Kotake and Knoop,

A., 1912, ii, 81). It may be recrystallised from hot 10% acetic acid in the form of white, hygroscopic crystals, which darken at 250°, $[a]_D - 15·2°$. The substance may be titrated, using phenolphthalein, but it could not be shown that the magnesium which accompanies the crude protein is combined as a salt.   J. O. W.

Anthocyanin. III. An Anthocyanin-like Oxidation Product of Euxanthone. MAXIMILIAN NIERENSTEIN (*Ber.*, 1913, **46**, 649—650. Compare A., 1912, i, 42, 292).—When euxanthone (2 : 8-hydroxyxanthone) (I), which is obtained by treating Indian-yellow with hydrochloric acid and ammonia, is oxidised by chromic acid in glacial acetic acid, 2-*hydroxy*-5 : 8-*quinoxanthone* (II) is formed in small, sparkling, deep red needles, which give a blue solution in alkalis and a red in concentrated sulphuric acid. On reduction with zinc dust in acetic anhydride suspension, an amorphous product is obtained, which, on hydrolysis, yields 2 : 5 : 8-*trihydroxyxanthone* (III) in small, light yellow, silky needles with $2H_2O$, m. p. 328—330°. This compound, like its isomeride, gentisein, gives a blood-red colour with sodium amalgam, and its alcoholic solution dyes mordanted cotton. It forms a *triacetyl* derivative, $C_{19}H_{14}O_8$, in faintly yellow needles, m. p. 226—230°, and with diazomethane a *trimethoxyxanthone*, $C_{16}H_{14}O_5$, in pale yellow needles, m. p. 194—195°.

(I.)   (II.)   (III.)
J. O. W.

Action of Sodium Methoxide on Bilirubic Acid, Bilirubin, and Hemibilirubin. HANS FISCHER and HEINRICH ROSE (*Ber.*, 1913, **46**, 439—442).—Bilirubin and hemibilirubin resemble the earlier examined pyrrole derivatives (this vol., i, 71, Fischer and Bartholomäus, this vol., i, 209) in their behaviour towards sodium methoxide at elevated temperatures. When heated with sodium methoxide in alcoholic solution at 220—230°, each gives rise to 2 : 4 : 5-trimethyl-pyrrole-3-propionic acid (identified by the picrate ; compare Fischer and Bartholomäus, *loc. cit.*), together with a little xanthobilirubic acid (see below).

Bilirubic acid under similar treatment gives in good yield an acid *substance*, yellow prisms, m. p. 274°, for which the name *xanthobilirubic acid* (or *xanthopyrrolecarboxylic acid*) is proposed ; *sodium* salt sparingly soluble. It is possible that the acid is the pure form of the dehydrobilic acid of Piloty and Thannhauser (A., 1912, i, 925). On reduction by a mixture of hydriodic and acetic acids it is reconverted into bilirubic acid.

The above results must be regarded as a proof of the presence of a third pyrrole ring in bilirubin and hemibilirubin.   D. F. T.

The Identity of Baphinitone with Homopterocarpin. Hugh Ryan and R. Fitzgerald (*Proc. Roy. Irish Acad.*, 1913, 30, 106—108).—Baphinitone, $C_{17}H_{16}O_4$, obtained from barwood, forms colourless, acicular crystals, m. p. 84° (Anderson, T., 1876, ii, 582, gives m. p. about 88°, and formula $C_{26}H_{26}O_6$). In 4% solution in chloroform it has $[a]_D^{20} - 211·7°$. Similarly, homopterocarpin, obtained from santalin by the method of Cazeneuve and Hugounenq (A, 1887, 971; 1889, 160), was found to melt at 84° (Brooks, A., 1911, i, 154, gives 86°), and to have $[a]_D^{20} - 211°$ in 4% solution in chloroform. In appearance, solubility and m. p., homopterocarpin is identical with baphinitone, and a mixture of the two substances melts at the same temperature as each of its constituents.

A solution of homopterocarpin in chloroform reacts readily with bromine in bright sunlight with the formation of a *substance*, $C_{17}H_{14}Br_2O_4$, colourless needles, m. p. 200°, and of a yellow, amorphous *solid*. Contrary to Cazeneuve's statement, homopterocarpin does not yield methyl iodide when treated with hydriodic acid, and thus contains no methoxy-group; nevertheless, a phenolic substance is obtained by the action of hydriodic acid on it.　　　　　　　H. W.

Optical Activity of Tannin. Emanuel Navassart (*Zeitsch. Chem. Ind. Kolloide*, 1913, 12, 97—99).—The rotatory power of tannin solutions has been examined with reference to the influence of concentration. In the case of aqueous solutions, the rotatory power varies very considerably with the concentration, the value of $[a]_D^{20}$ increasing from 49·8° to 89·7° when the concentration falls from 20% to 0·08%. When dissolved in ethyl alcohol, acetone, and acetic acid, the rotatory power of tannin is much smaller, and varies less with the concentration. For concentrations between 1% and 20%, the observed values of $[a]_D^{20}$ vary from 12·7° to 16·9° in alcohol, from 12·9° to 15·1° in acetone, and from 9·4° to 14·5° in acetic acid. These results seem to show that the rotatory power of the tannin increases as the degree of dispersity of the substance in the various solvents diminishes.

[Preparation of Derivatives of Benzanthrone Containing Sulphur.] Gesellschaft für Chemische Industrie (D.R.-P. 254098). —The action of chlorine (or chlorinating reagents) on 2-methylbenzanthrone (m. p. 199°) gives rise to *chloromethylbenzanthrone*, m. p. 175°; this, when heated with sulphur or polysulphides during two hours at 200—240°, yields the *compound* (annexed formula), glistening, coppery needles.
The preparation of *bromomethylbenzanthrone, dichloro-2-methylbenzanthrone*, and of *nitro-* and *amino-benzanthrone* with their sulphur derivatives is also described.　　　　　　　F. M. G. M.

Preparation of Homologues of Hydroquinine. VEREINIGTE CHININFABRIKEN ZIMMER & Co. (D.R.-P. 254712. Compare A., 1892, 1253).—The alkylation of hydrocupreine has furnished the following derivatives : *Ethylhydrocupreine*, $C_{21}H_{28}O_2N_2$, is amorphous, but its *sulphate* forms colourless needles, whilst *propylhydrocupreine*, $C_{22}H_{30}O_2N_2$, colourless crystals, has m. p. 142°.   F. M. G. M.

Alkaloids of Javanese Coca [Erythroxylon novogranatense]. ANNE W. K. DE JONG (*Rec. trav. chim.*, 1911, 30, 204—210 ; 1912, 31, 249—259. Compare A , 1906, ii, 315).—The method of analysis previously described has been slightly modified, since it is found that the insoluble barium salts, obtained by heating the alkaloids with barium hydroxide, contain small quantities of barium cinnamate in addition to barium β-truxillate. The cinnamic acid is recovered by agitating the mixed acids with chloroform. The mixed acids obtained from the soluble barium salts are also treated with chloroform, when α-truxillic acid, possibly containing also the β-isomeride, remains. The acids obtained from the chloroform solution were found to contain about 50·3% cinnamic acid and 37 9% benzoic acid.

A second specimen of mixed acids was obtained by decomposing the alkaloids by means of hot hydrochloric acid and solution of the product in ether, which left a small residue of impurities. The ethereal solution was shaken with potassium hydroxide, the latter acidified with hydrochloric acid, and again treated with ether, whereby a small quantity of α-truxillic acid remained undissolved. The ethereal solution was evaporated to dryness, and the residue extracted with chloroform, which left a small residue consisting of a mixture of α- and β truxillic acids. The acids obtained from the chloroform solution contained 52·1% cinnamic acid, and 34% benzoic acid mixed with acids of higher molecular weight or with neutral substances.

In the second paper the author has worked out a process for the separation of the acids obtained by the decomposition of the alkaloids of Javanese coca, and has ascertained the presence of the following substances in a specimen of these acids : cinnamic, benzoic, *allo*cinnamic, α-truxillic, β-truxillic and δ-truxillic acids, resinous acids, and neutral substances, together with an acid, m. p. about 150° (probably identical with protococaic acid obtained by Hesse, A., 1903, i, 192), and an acid, m. p. about 190°, possibly identical with β-cocaic acid.

The properties of the truxillic acids and their salts have been investigated. The former are insoluble in light petroleum, but are dissolved in the presence of benzoic or cinnamic acids, the solubility of the α- and γ-acids being, however, only slightly affected. α-, β-, and γ-Truxillic acids are only sparingly soluble in chloroform at the ordinary temperature. Hot chloroform dissolves the β-acid, particularly in the presence of benzoic and cinnamic acids. The δ-acid is soluble in chloroform. The α- and γ-acids are insoluble in benzene, whereas the β- and δ-acids are more soluble in the hot than in the cold solvent. The latter acids may be crystallised from boiling water, in which the α- and γ-acids are but slightly soluble.

One hundred c.c. of an aqueous solution of barium β-truxillate, saturated at 26°, contain 0·028 gram of the salt.

The following salts are sparingly soluble in water : the zinc, cadmium, iron, lead, copper, mercury, and silver salts of the α-acid ; the calcium, barium, strontium, zinc, cadmium, manganese, iron, cobalt, nickel, lead, copper, mercury, and silver salts of the β-acid ; the lead, copper, mercury, and silver salts of the γ-acid ; the same salts of the δ- as of the β-acid, and in addition the magnesium salt. The magnesium salt of the β-acid is soluble in water.　　　　　　　　　　H. W.

Preparation of Therapeutically Valuable Double Salts from Morphine and Narcotine. C. F. BOEHRINGER & SOEHNE (D.R.-P. 254502).—The following therapeutically valuable double salts are readily obtained by treating a hot alcoholic solution of the acid with the requisite amount of the other components. *Morphine narcotine meconate*, $C_7H_4O_7,C_{17}H_{19}O_3N,C_{22}H_{23}O_7N,4H_2O$. *Morphine dinarcotine benzenetrisulphonate*, $C_6H_3(SO_3H)_3,C_{17}H_{19}O_3N,(C_{22}H_{23}O_7N)_2,2H_2O$. *Morphine narcotine phenoldisulphonate,*

$$OH\cdot C_6H_3(SO_3H)_2,C_{17}H_{19}O_3N,C_{22}H_{23}O_7N,2H_2O.$$
Morphine dinarcotine disulphosalicylate,

$$OH\cdot C_6H_3(SO_3H)_2\cdot CO_2H,C_{17}H_{19}O_3N,(C_{22}H_{23}O_7N)_2,H_2O.$$
Dimorphine narcotine disulphosalicylate,

$$OH\cdot C_6H_3(SO_3H)_2\cdot CO_2H,(C_{17}H_{19}O_3N)_2 C_{22}H_{23}O_7N,2H_2O.$$
Morphine narcotine sulphate, $H_2SO_4,C_{17}H_{19}O_3N,C_{22}H_{23}O_7N,4\tfrac{1}{2}H_2O$. They form colourless crystals, sparingly soluble in cold, readily in hot water, and somewhat insoluble in the ordinary organic media.

F. M. G. M.

Preparation of Morphine Esters of Alkyl- and Aryloxy-fatty Acids. CHEMISCHE FABRIK VON FRIEDR HEYDEN (D.R.-P. 254094).—*Diethoxyacetylmorphine*, an oil, is prepared by heating morphine (10 parts) with ethoxyacetic anhydride (37 parts) during several hours at 40—45° ; the *hydrochloride*, glistening leaflets, decomposes at about 142°.

Ethoxyacetylmorphine, m. p. 155° (about), is obtained accompanied by the foregoing compound when the proportions of the reacting components are varied, and the mixture heated at 40—50° ; the *hydrochloride,* needles, has m. p. 183—186°. *Diphenoxyacetylmorphine,* m. p. 125° (decomp.), faintly-coloured crystals, is prepared in an analogous manner.　　　　　　　　　　　　　　　　F. M. G. M.

Alkaloids of Pareira Root. MAX SCHOLTZ (*Arch. Pharm.*, 1913, **251**, 136—151. Compare A., 1913, i, 87, and Faltis, 1912, i, 796).—As the result of further analyses, the author now reverts to the formula $C_{18}H_{21}O_3N$, which he used originally for the bebeerines. Bebeerine, *iso*-bebeerine, and β-bebeerine can all be represented by the extended formula $OH\cdot C_{16}H_{14}O(OMe):NMe$. The first and third isomerides yield with acetic anhydride the same optically inactive hydroxytriacetylbebeerine. The latter appears to be formed by the opening of a ring containing nitrogen, the attachment of an acetyl group to the N-atom, and of the residue $CH_3\cdot CO\cdot O$ to the carbon atom formerly linked to the N-atom.

*iso*Bebeerine yields two hydroxytriacetyl*iso*bebeerines, one dextro-rotatory and the other inactive.

*iso*Bebeerine, $C_{18}H_{21}O_3N$, m. p. 297° (decomp.), is the chief constituent of "crystallised bebeerine sulphate" (Merck); the *hydriodide*, m. p. 300° (approx. decomp.), forms prisms from water; the *hydrochloride* is precipitated as colourless needles on adding hydrochloric acid to a solution of the sulphate; the *methiodide*, B,MeI, m. p. 275° (decomp.), forms large, prismatic crystals containing water of crystallisation. On heating with acetic anhydride, *iso*bebeerine yields (1) *α-hydroxy-triacetyl*isobebeerine, m. p. 130—140°, $[a]_D^{20} + 68·1°$ in pyridine, which is colourless and amorphous, and *β-hydroxytriacetyl*isobebeerine, m. p. 291° (approx.), $[a]_D = 0°$, which crystallises in colourless needles and is only soluble in pyridine. On hydrolysis by sodium hydroxide in alcohol, each triacetyl derivative yields a corresponding *hydroxymono-acetyl*isobebeerine; the α-compound, m. p. 280° (approx.), crystallises in colourless, slender needles, and the β-isomeride, m. p. 332° (approx.), forms microscopic needles. Both are insoluble, except in solutions of the alkali hydroxides. *Benzoyl*isobebeerine, m. p. 215° (approx.), obtained by the action of benzoic anhydride on *iso*bebeerine, crystallises from alcohol in glancing, yellow leaflets.

β-Bebeerine, $C_{18}H_{21}O_3N$, is amorphous, but yields a crystalline *methiodide*, B,MeI, m. p. 80° (hydrated) or 258—259° (dry, decomp.). Both bebeerine and β-bebeerine on heating with acetic anhydride yield the same *hydroxytriacetylbebeerine*, $C_{24}H_{29}O_7N$, m. p. 125—135°, which is amorphous, and loses two acetyl groups on treatment with potassium hydroxide in alcohol.   T. A. H.

Zygadenine, the Crystalline Alkaloid of Zygadenus inter-medius. FREDERICK W. HEYL, F. E. HEPNER, and SYLVESTER K. LOY (*J. Amer. Chem. Soc.*, 1913, **35**, 258—262).—It has been shown already (A., 1911, ii, 325) that the leaves of *Zygadenus intermedius* yield 0·3—0·4% of a mixture of alkaloids. Further work on this subject has resulted in the isolation of a pure alkaloid, *zygadenine*, $C_{39}H_{63}O_{10}N$, m. p. 200—201°, $[a]_D - 48·2°$, which crystallises from benzene in clusters of lustrous needles, and from alcohol in ortho-rhombic prisms containing 2Et·OH; the *aurichloride* forms long, dense prisms. The alkaloid gives a yellowish-orange coloration with concentrated sulphuric acid, changing to a brilliant cherry-red. Its physiological action resembles that of veratrine.   E. G.

Electrochemical Reductions. III. Reduction of Nitroso-amines. HILMAR JOHANNES BACKER (*Rec. trav. chim.*, 1913, **32**, 39—47. Compare A., 1912, i, 339, 730).—Nitrosopiperidine suspended in sulphuric acid (10%) was electrolysed at a cathode of tinned copper when an 81% yield of the corresponding hydrazine (estimated by oxidation to the tetrazone) was obtained (compare Knorr, A., 1884, 467; Ahrens, A., 1897, i, 369). At a platinum electrode, the hydrogen was incompletely utilised, and the yield of hydrazine sank to 32%. An excess of hydrogen was found to be practically without effect on the hydrazine.

Diaminopiperazine was obtained in 55% yield by the action of zinc

dust and acetic acid on dinitrosopiperazine (compare Schmidt and Wichmann, A., 1892, 210). Electrolytic reduction at a tinned copper cathode of a suspension of the latter in a mixture of acetic and sulphuric acids gave a 38% yield of diaminopiperazine, which, however, increased to 72% when the mixture of acids was replaced by an aqueous solution of sodium sulphate to which a few drops of sulphuric acid had been added. An attempt to convert dinitrosopiperazine into dinitropiperazine by the action of nitric acid was unsuccessful.

Phenylmethylhydrazine (compare Fischer, A., 1878, 312; 1887, 138) was formed by electrolytic reduction of phenylmethylnitrosoamine suspended in dilute acetic acid at a tinned copper cathode. The yield was 79% of the theoretical.

α-Nitroso-α-methylcarbamide, $NH_2 \cdot CO \cdot NMe \cdot NO$, was readily reduced in sulphuric acid suspension at a tin cathode with the formation of methylsemicarbazide (compare Brüning, A., 1890, 23; Young and Oates, T., 1901, 79, 662), which was identified by conversion into benzylidenemethylsemicarbazone, white needles, m. p. 163°. Young and Oates (loc. cit.) give 159—160° as m. p. of this substance, whilst Michaelis and Hadanck (A., 1908, i, 1020) found 162°.   H. W.

Indole. RUDOLF WEISSGERBER (Ber., 1913, 46, 651—659).—The difficulty experienced in preparing derivatives of indole is chiefly due to the lability of the imino-hydrogen atom. If this atom is replaced by a group which can be subsequently removed, it is found possible to obtain halogen derivatives by direct substitution and to disrupt the indole ring so that anthranilic acid results.

[With ARNO KLEMM.]—Halogens react violently with indole, and only by working in very dilute solutions could Pauly and Gundermann obtain iodoindole (A., 1909, i, 71). When 1-benzoylindole (A., 1911, i, 155), however, is treated in the cold with bromine in carbon disulphide, bromo-1-benzoylindole, $C_{15}H_{10}ONBr$, is obtained in thick plates, m. p. 97—98°, which may be hydrolysed by dilute ammonia or, more conveniently, by means of sodium ethoxide in alcoholic solution, when water precipitates bromoindole, C_8H_6NBr, in silvery leaflets which have a strong fœcal odour and undergo vigorous decomposition at 67°. The compound is not very stable, but the bromine atom resists the action of alkalis.

1-Benzoylindole also combines with chlorine, and the chloro-1-benzoylindole, colourless prisms, m.p. 97—99°, may be hydrolysed to the chloroindole which Mazzara and Borgo obtained by the action of sulphuryl chloride on indole (A., 1906, i, 304). Since the benzoyl derivatives may be oxidised to benzoylanthranilic acid, the halogen is present in the pyrrole ring, and, from their similarity to Pauly's 3-iodo-indole, the constitution of which was satisfactorily determined, the conclusion is drawn that the bromo- and chloro-derivatives are also substituted in position 3, although all three compounds give 2-oxindole when treated with dilute acids.

[With O. HERZ.]—The oxidation of indole itself results in the formation of amorphous masses, but the benzoyl compound is readily converted by permanganate in acetone solution into benzoylanthranilic acid, and this, by hydrolysis, into anthranilic acid itself.

[With F. Kraft.]—The conversion of an indole derivative into indigotin has been accomplished by passing ozone through a strongly alkaline solution of 3-indolecarboxylic acid (A., 1911, i, 155). The reaction commences quickly, but the yield is only about 38%, anthranilic acid being isolated from the by-products. Other oxidising agents do not yield indigotin, neither does 2-indolecarboxylic acid give rise to that dye. J. C. W.

Preparation of Substituted Indoles by the Catalytic Decomposition of Hydrazones. ALEXANDER E. ARBUZOV and V. M. TICHVINSKI (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 70—74).— When heated with cuprous chloride or bromide, or platinous or zinc chloride, hydrazones of aldehydes and ketones undergo catalytic decompositions in directions depending on their structures and on the magnitudes of the radicles present. In the cases already investigated, the principal products are substituted indole derivatives.

Methyl-ethyl-ketone-phenylhydrazone (50 grams), when heated at 180—230° in presence of cuprous chloride (0·1 gram), yields 2 : 3-dimethylindole, the yield being about 60%.

Similarly, propaldehydephenylhydrazone gives skatole in 73—74% yield, whilst propaldehydetolylhydrazone gives 3 : 5-dimethylindole, $C_{10}H_{11}N$, which crystallises in feathery masses of colourless, silky needles, m. p. 74—74·5°. T. H. P.

5-, 6-, and 8-Iodoquinolines and Their Derivatives. JOHANN HOWITZ, HEDWIG FRAENKEL, and ELSE SCHROEDER (*Annalen*, 1913, **396**, 53—75).—8-Aminoquinoline is obtained by the reduction of 8-nitroquinoline best by iron and acetic acid. When tin or stannous chloride and hydrochloric acid are used, the resulting 8-aminoquinoline is contaminated with 5-chloro-8-aminoquinoline. 8-*Iodoquinoline*, C_9NH_6I, m. p. 36°, colourless needles, prepared from diazotised 8-aminoquinoline in the usual manner, forms a *platinichloride*,

$$2C_9NH_6I,H_2PtCl_6,2H_2O,$$
m. p. 251°, orange needles, and *methiodide*, m. p. 200°, yellow needles. By oxidation with alkaline potassium ferricyanide, the latter yields

8-*iodo*-1-*methyl*-2-*quinolone*, $C_9H_3I<^{NMe\cdot CO}_{CH=CH}$, m. p. 168°.

The 8-iodoquinoline, m. p. 136°, described by Claus and Grau in 1893, is 5-chloro-8-iodoquinoline, produced from the impure 8-amino-quinoline mentioned above.

8-Iodoquinoline is readily nitrated by concentrated sulphuric acid and nitric acid (D 1·5) in the cold, yielding 8-*iodo*-5-*nitroquinoline*, m. p. 192°, pale yellow needles. 8-*Iodo*-5-*aminoquinoline*,

$$C_9NH_5I\cdot NH_2,H_2O,$$
m. p. 148° (anhydrous, 155°), brown prisms (*benzoyl* derivative,

$$C_{16}H_{11}ON_2I,H_2O,$$
m. p. 218°, leaflets), yields 5 : 8-*di-iodoquinoline*, m. p. 162°, and 5-*chloro*-8-*iodoquinoline*, m. p. 138°, by the usual methods.

By the Sandmeyer process, 5-aminoquinoline yields 5-chloroquinoline, m. p. 44—45° (Claus and Junghanns give 31°), the nitration of which

produces 5-chloro-8-nitroquinoline, m. p. 136° (184°, Claus and Junghanns). 5-Chloro-8-aminoquinoline, m. p. 75° (69°, Claus and Junghanns), forms an *acetyl* derivative, m. p. 140°, and is converted into 5-chloro-8-iodoquinoline by the usual method.

8-Iodoquinoline is readily attacked by 40% fuming sulphuric acid in the cold, yielding 8-*iodoquinoline-5-sulphonic acid*, $C_9NH_5I\cdot SO_3H$, silver-grey leaflets, of which the *sodium* and *barium* salts are described. The *silver* salt, $C_9NH_5I\cdot SO_3Ag,\frac{1}{2}H_2O$, when dehydrated, reacts with methyl iodide at 120—130° to form chiefly the *betaine*, m. p. 292° (decomp.), of 8-iodo-1-methylquinoline-5-sulphonic acid, and with ethyl iodide at 130—140° to form *ethyl 8-iodoquinoline-5-sulphonate*,

$$C_9NH_5I\cdot SO_3Et,$$
m. p. 156°, colourless leaflets, and the *betaine*, m. p. about 340° (decomp.), of 8-iodo-1-ethylquinoline-5-sulphonic acid. Sodium 8-iodo-quinoline-5-sulphonate and phosphorus pentachloride at 125—130° yield 8-*iodoquinoline-5-sulphonyl chloride*, m. p. 116°, yellow needles or prisms, from an ethereal solution of which and dry ammonia the *sulphonamide*, $C_9NH_5I\cdot SO_2\cdot NH_2$, m. p. 212°, is obtained. The position of the sulpho-group in 8-iodoquinoline-5-sulphonic acid is proved by nitration, whereby the sulpho- is replaced by the nitro-group, and 8-iodo-5-nitroquinoline, m. p. 192°, is obtained.

5-Iodoquinoline methiodide is oxidised to 5-*iodo-1-methyl-2-quinolone*, m. p. 172°, yellow leaflets, by alkaline potassium ferricyanide. 5-*Iodo* 8-*nitroquinoline*, m. p. 160°, yellow needles, obtained by the nitration of 5-iodoquinoline on the water-bath, yields by reduction 5-*iodo-8-aminoquinoline*, m. p. 122°, brown needles (*benzoyl* derivative, m. p. 161°), from which 5 : 8-di-iodoquinoline, m. p. 161°, and 8-*chloro-5-iodoquinoline*, m. p. 118°, are prepared by the usual methods; the formation of the di-iodo-compound determines the orientation of the nitro-group in nitrated 5-iodoquinoline.

The following derivatives of 6-iodoquinoline have been prepared: 6-*Iodo-1-methyl-2-quinolone*, $C_{10}H_8ONI$, m. p. 129°, yellow needles or leaflets; 6-*iodo-5-aminoquinoline*, m. p. 176° (*acetyl* derivative,

$$C_{11}H_9ON_2I,H_2O,$$
m. p. 197°); 5 : 6-*di-iodoquinoline*, m. p. 125°, and 5-*chloro-6-iodo-quinoline*, m. p. 141°. C. S.

2-*op*-Dinitrophenyl*iso*quinolinium Chloride and its Products of Transformation. THEODOR ZINCKE and G. WEISSPFENNING (*Annalen*, 1913, **396**, 103—131).—The authors' experiments have not realised their expectations that the action of arylamines or of cyanogen bromide on 2-*op*-dinitrophenyl*iso*quinolinium chloride would yield the glutacondialdehyde derivative, $CHO\cdot C_6H_4\cdot CH_2\cdot CHO$, or colour bases, $NAr{:}CH\cdot C_6H_4\cdot CH{:}CH\cdot NHAr$, analogous to those obtained in the pyridine series (A., 1904, i, 448, 921; 1905, i, 467, 923; 1907, i, 625).

2-op-*Dinitrophenylisoquinolinium chloride*,

$$C_6H_3(NO_2)_2\cdot NCl{<}{{}^{CH\cdot C_6H_4}_{CH:CH}},$$
decomp. 130°, stout, rhombic crystals, is obtained by keeping an ethereal solution of *iso*quinoline and 1-chloro-2 : 4-dinitrobenzene for

several weeks or months at the ordinary temperature. It forms a *platinichloride*, m. p. 222°, and *periodide*, $C_{15}H_{10}O_4N_3I_8$, dark brown needles, and is readily hydrolysed by hot aqueous sodium nitrite, yielding *iso*quinoline, hydrogen chloride, and 2 : 4-dinitrophenol (in the form of the dinitrophenyl*iso*quinolinium and *iso*quinoline salts; the latter has m. p. 127°). Hydrogen sulphide decomposes the chloride, 2 : 4-dinitrophenyl mercaptan being produced in the aqueous solution and 2 : 4-dinitrophenyl sulphide in alcoholic solution.

Dinitrophenyl*iso*quinolinium chloride is converted by aqueous ammonia or sodium carbonate or by an aqueous solution of methyl-amine or aniline, less satisfactorily by aqueous sodium hydroxide, into the ψ *base*, $C_6H_8(NO_2)_2 \cdot N {<}^{CH(OH) \cdot C_6H_4}_{CH =\!=\!= CH}$, orange-red needles, m. p. 141—142°, darkening at about 90°, which is reconverted into dinitrophenyl*iso*quinolinium chloride by dilute hydrochloric acid, and yields ethers, $C_6H_8(NO_2)_2 \cdot N {<}^{CH(OR) \cdot C_6H_4}_{CH =\!=\!= CH}$, by warming with alcohols; the *methyl ether*, m. p. 149°, dark red crystals, *ethyl ether*, m. p. 135°, pale red prisms, and iso*butyl ether*, m. p. 122°, orange-red crystals, have been prepared. These ethers, which are also produced directly from dinitrophenyl*iso*quinolinium chloride and ammonia dissolved in the alcohol, are converted one into another by warming with the necessary alcohol.

By heating with water at 90—95° for some hours, or with acetone at 100°, or with boiling acetic anhydride, the freshly precipitated ψ-base is converted into an *isomeride*, m. p. 151°, dark red crystals with a violet shimmer. The isomeride is only slowly attacked by warm dilute hydrochloric acid, does not form ethers by boiling with alcohols, and is slowly converted into dinitrophenyl*iso*quinolinium chloride by hot concentrated hydrochloric acid. It does not react with phenylhydrazine, and is, therefore, not the aldehydo-base, $CHO \cdot C_6H_4 \cdot CH{:}CH \cdot NH \cdot C_6H_8(NO_2)_2$; probably it has the constitution $NHR \cdot CH{:}CH \cdot C_6H_4 \cdot CH(OH) \cdot O \cdot CH {<}^{NR - CH}_{C_6H_4 \cdot CH}$ [where R is $C_6H_8(NO_2)_2$], and is formed by the union of the ψ-base and the aldehydo-base.

When boiled in alcoholic solution with aniline or *p*-toluidine, dinitrophenyl*iso*quinolinium chloride or, better, the ψ-base or the violet isomeride is decomposed into 2:4-dinitroaniline and the 2-aryl*iso*quinolinium chloride. 2-*Phenyliso*quinolinium chloride, $C_{15}H_{12}NCl, 2H_2O$, long needles, forms a *platinichloride*, m. p. 228—229°, orange needles, and *mercurichloride*, m. p. 183—184°; the *dichromate*, decomp. about 195°, and *picrate*, m. p. 136—137°, yellow needles, are described. 2-*p*-*Tolyl*iso-*quinolinium chloride*, $C_{16}H_{14}NCl, 2H_2O$, colourless needles, forms a *platinichloride*, m. p. 216—217°, orange-yellow needles.

Dinitrophenyl*iso*quinolinium chloride is converted into the ψ-base by hydrazine hydrate, but reacts with phenylhydrazine in boiling alcohol just as does dinitrophenylpyridinium chloride (A., 1904, i, 448), yielding the *dinitroanilinophenylhydrazone*,

$$C_6H_8(NO_2)_2 \cdot NH \cdot CH{:}CH \cdot C_6H_4 \cdot CH{:}N \cdot NHPh,$$
m. p. 183—184°, black needles. In a similar manner the *dinitro-anilino*-p-*tolylhydrazone*, $C_{22}H_{19}O_4N_5$, m. p. 185—186°, black leaflets with a red shimmer, and the *dinitroanilino-phenylmethylhydrazone*, $C_{22}H_{19}O_4N_5$, m. p. 181—182°, reddish-brown leaflets, have been obtained. These three substances are decomposed by boiling alcohol and hydrochloric acid, D 1·19, into 2 : 4-dinitroaniline and 2-*anilino*iso-quinolinium chloride, $C_9H_7N(NHPh)Cl$, m. p. 198—200°, faintly yellow, monoclinic prisms (*platinichloride*, m. p. 190° [decomp.]), 2-p-*toluidino*isoquinolinium *chloride*, rhombic plates, and 2-*methylanilino*-isoquinolinium *chloride*, faintly yellow needles (*picrate*, m. p. 170°; *platinichloride*, m. p. 185°; *mercurichloride*, m. p. 174°), respectively. 2-Anilino*iso*quinolinium chloride yields *iso*quinoline (aniline could not be detected) by reduction with zinc dust and dilute hydrochloric acid, and by treatment with aqueous sodium hydroxide, sodium carbonate, or ammonia yields a red precipitate which is apparently a mixture of the

ψ-base, $C_9H_4{<}^{CH(OH)\cdot N\cdot NHPh}_{CH=\!=\!=CH}$, and the azo-compound,

$C_6H_4{<}^{CH:N:NPh}_{CH:CH}$. C. S.

Bromination of 6-Methylquinoline and 6-Quinolinealdehyde.

JOHANN HOWITZ and J. PHILIPP (*Annalen*, 1913, **396**, 23—37).—The dibromide of 6-methylquinoline hydrobromide is obtained as a brick-red, crystalline powder by saturating a cold chloroform solution of 6-methylquinoline with hydrogen bromide and subsequently adding bromine (1 mol.). By carefully heating it at 170—180° for two hours, cooling to 140°, and adding more bromine (1 mol.), and heating again at 170—180° for two hours, the substance is converted into 6-*dibromomethylquinoline*, $C_9NH_6\cdot CHBr_2$, m. p. 159—160°, white needles (*platinichloride*, $2C_{10}H_7NBr_2,H_2PtCl_6$, m. p. 235°, orange crystals), and 3-*bromo* 6-*dibromomethylquinoline*, $C_{10}H_6NBr_3$, m. p. 141°, yellowish-white needles, each of which loses two atoms of bromine by hydrolysis with alcoholic potassium hydroxide.

By boiling with water for ten to fifteen minutes and basifying, 6-dibromo-methylquinoline is converted into 6-*quinolinealdehyde*, $C_{10}H_7ON$, glistening needles containing H_2O, m. p. 55° (anhydrous, 75—76°), which exhibits the usual reducing and additive properties of an aldehyde. It yields quinoline 6-carboxylic acid by oxidation, forms a *platinichloride*, $2C_{10}H_7ON,H_2PtCl_6$, m. p. 244°, reddish-yellow needles, *aldazine*, $N_2(:CH\cdot C_9NH_6)_2$, m. p. 261°, yellow needles, *semicarbazone*, m. p. 239°, *oxime*, m. p. 191°, *phenylhydrazone*, m. p. 185°, yellow crystals containing H_2O, *anil*, $NPh:CH\cdot C_9NH_6$, m. p. 99°, and o-*tolil*, m. p. 97°, and condenses with dimethylaniline in the presence of zinc chloride to form *tetramethyldiaminodiphenyl-6-quinolylmethane*,

$C_9NH_6\cdot CH(C_6H_4\cdot NMe_2)_2$,
m. p. 160°, almost colourless needles, which yields a green *dye* by oxidation with lead peroxide. When heated with methyl iodide at 100°, 8-quinolinealdehyde yields a *methiodide*, $CHO\cdot C_9H_6NMeI$, m. p. 218°; the latter is oxidised by cold alkaline potassium ferricyanide to

1-*methyl*-2-*quinolone*-6-*aldehyde*, $CHO\cdot C_9H_5{<}^{NMe\cdot CO}_{CH=CH}$, m. p. 164°,

colourless needles, or the corresponding *acid*, $C_{11}H_9O_3N$, m. p. above 300°, according to the duration of the reaction.

3-Bromo-6-dibromomethylquinoline is hydrolysed by an excess of potassium carbonate and a little water at 115—120°, yielding *3-bromo-quinoline-6-aldehyde*, m. p. 139°, white needles (*aldazine*, m. p. 194°, pale yellow needles, *oxime*, m. p. 217°; *phenylhydrazone*, m. p. 195°; *anil*, m. p. 124°), in which the position of the halogen is determined by its oxidation to 3-bromopyridine-5 : 6-dicarboxylic acid by hot alkaline potassium permanganate. By oxidation with chromic and sulphuric acids, the aldehyde yields *3-bromoquinoline-6-carboxylic acid*, m. p. 245°, long white needles.   C. S.

8-Quinolyl Ketones and their Derivatives. JOHANN HOWITZ and O. KOPKE (*Annalen*, 1913, **396**, 38—52).

—Hitherto, only quinolyl ketones have been known containing the carbonyl group attached to the pyridine nucleus. Bromoquinolines and 8-bromomethylquinoline do not react with magnesium in ether. The interaction of 8-quinol-inealdehyde (Howitz and Schwenk, A., 1905, i, 471) and magnesium phenyl bromide in ether at 0°, leads to the formation of *phenyl-8-quinolylcarbinol*, $OH\cdot CHPh\cdot C_9NH_6$, m. p. 104°, large colourless plates, in about 60% yield. The carbinol forms a *platinichloride*, m. p. 198° (decomp.), and a *benzoate*, m. p. 146°, and is oxidised by chromic and acetic acids on the water-bath to *phenyl 8-quinolyl ketone*,

$$COPh\cdot C_9NH_6,$$
m. p. 94°, colourless plates (*platinichloride*, m. p. 213° [decomp.]). By treatment with hydroxylamine hydrochloride and potassium hydroxide in boiling alcohol, the ketone yields an *oxime*, $C_{16}H_{12}ON_2,H_2O$, m. p. 121°, which is converted into an *isomeride*, $C_{16}H_{12}ON_2,H_2O$, m. p. 165°, by heating at 120°, and then crystallising from alcohol. By treating a cold ethereal solution of the oxime, m. p. 121°, with phosphorus pentachloride, and decomposing the precipitated imino-chloride with water at 0°, *8-benzoylaminoquinoline*, $C_9NH_6\cdot NHBz$, m. p. 93°, is obtained, the identity of which is established by its formation by the benzoylation of 8-aminoquinoline and by its decomposition into 8-aminoquinoline and benzoic acid by concentrated hydrochloric acid at 160°. The oxime, m. p. 121°, is therefore anti-*phenyl 8-quinolyl ketoxime*, $\begin{matrix} C_9NH_6\cdot CPh \\ HO\cdot N \end{matrix}$. In a similar manner, the oxime, m. p. 165°, is proved to be syn-*phenyl 8-quinolyl ketoxime*, $\begin{matrix} C_9NH_6\cdot CPh \\ N\cdot OH \end{matrix}$, by its conversion by the Beckmann transformation into the anilide of quinoline-8-carboxylic acid; unfortunately, neither the anilide nor the quinolinecarboxylic acid produced by its hydrolysis has been isolated, but only the aniline resulting in the latter operation.

Phenyl 8-quinolyl ketone forms a *phenylhydrazone*, m. p. 190°, *semicarbazone*, m. p. 188°, and *azine*, $C_{32}H_{22}N_4$, m. p. 287°.

8-Quinolylmethylcarbinol, $OH\cdot CHMe\cdot C_9NH_6$, m. p. 65° (*platini-chloride*, m. p. 197° [decomp.], orange-yellow crystals; *benzoate*, m. p. 100°), obtained ultimately from magnesium methyl iodide and 8-quinolinealdehyde in ether, is oxidised to *8-quinolyl methyl ketone*, $C_9NH_6\cdot COMe$, m. p. 45°, b. p. about 295°, by potassium dichromate

and very dilute sulphuric acid on the water-bath. The ketone forms a *semicarbazone*, m. p. 223°, and an *oxime*, m. p. 137°; the latter has only been obtained in one modification, which is *syn*-8-quinolyl methyl ketoxime, since it yields 8-acetylaminoquinoline by the Beckmann transformation.

8-*Quinolylethylcarbinol* (*platinichloride*, m. p. 210° [decomp.]; *benzoate*, m. p. 82°) and 8-*quinolyl ethyl ketone*, b. p. about 290° (*semicarbazone*, m. p. 203°), have been prepared by methods similar to the preceding.

C. S.

Preparation of 9-Methylcarbazole. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 255304).—The technically valuable 9-methylcarbazole can be prepared in about 70% yield by the following method.

Dry potassium carbazole is heated with freshly distilled ethyl chloroacetate during about three hours, yielding *ethyl carbazole-9-acetate*, m. p. 97°; this when hydrolysed with an alkaline hydroxide gives rise to *carbazole-9-acetic acid*, glistening, colourless leaflets, m. p. 215°, which, when carefully heated at 250—270°, evolves carbon dioxide and furnishes pure 9-methylcarbazole, m. p. 87°. F. M. G. M.

Kehrmann's Interpretation of Chromo-Isomeric Acridonium Salts as "Quinhydrone Salts" which Contain Hydroacridine. ARTHUR HANTZSCH (*Ber.*, 1913, 46, 682—684. Compare this vol., i, 298).—Kehrmann's view that the dark green iodide obtained from methylphenazonium salts is a quinhydrone salt composed of one molecule of azonium tri-iodide and two molecules of methyldihydrophenazine, is combated.

According to Kehrmann, the salt should be decomposed by water into phenylmethylacridonium iodide, phenylmethylhydroacridine, and hydrogen iodide, but in reality it gives a clear, neutral solution, and behaves as a normal binary electrolyte. J. C. W.

"Halochromism" of the Derivatives of Phenyl*iso*oxazolone and of the Indogenides. ANDRÉ MEYER (*Compt. rend.*, 1913, 156, 714—717. Compare Baeyer and Villiger, A., 1901, i, 658; 1902, i, 380, 769; Meyer, A., 1912, i, 1019).—The indogenides and in particular the *iso*oxazole-indogenides give coloured compounds with acids and metallic salts, comparable to the oxonium salts, and the author has prepared a number of such compounds.

On passing dry hydrogen chloride into a suspension of piperonylidene-*iso*oxazolone in benzene at − 10°, a deep red additive *compound* is formed and crystallises out.

Condensation products are also formed from the *iso*oxazolones and stannic chloride, ferric chloride, or aluminium chloride, and a number of such stannichlorides, prepared by the addition of anhydrous staunic chloride to benzene solutions of the *iso*oxazolones, are described.

Phenylbenzylideneisooxazolone stannichloride, $C_{16}H_{11}O_2N,SnCl_4$, a yellow, microcrystalline powder, decomposes at 200°.

Phenylpiperonylidene-isooxazolone stannichloride, $C_{17}H_{11}O_4N,SnCl_4$, deep red leaflets, decomposes at 160°.

Phenylanisylideneisooxazolone stannichloride, $C_{17}H_{13}O_3N,SnCl_4$, a deep yellow powder, decomposes at 155°.

Phenyl-o-methoxybenzylideneisooxazolone stannichloride,
$$2C_{17}H_{13}O_3N,SnCl_4,$$
an orange powder, decomposes at 130°.

Phenylvanillylideneisooxazolone stannichloride, $C_{17}H_{13}O_4N,SnCl_4$, a brownish-red, microcrystalline powder, decomposes at 150°.

Phenyldimethylaminobenzylideneisooxazolone stannichloride,
$$C_{18}H_{16}O_2N_2,2SnCl_4,$$
a bright red powder, decomposes above 250°.
The indogenides furnish similar compounds, such as *piperonylidene-hydroxythionaphthen stannichloride*, $C_{15}H_{10}O_3S,SnCl_4$, a violet-black, microcrystalline powder, decomposing at 230°.

All these substances are hydrolysed by water and are practically insoluble in organic solvents, their colours being deeper than those of the parent substances.

The mixed azo-derivatives of phenylisooxazolone are also "halo-chromes" and give coloured stannichlorides, the one described being *benzeneazophenylisooxazolone stannichloride*, $C_{15}H_{11}O_2N_3,SnCl_4$, an orange-yellow powder, decomposing at 130°.   W. G.

Some Derivatives of the Methoxyphenylisooxazolones. ANDRÉ WAHL and C. SILBERZWEIG (*Bull. Soc. chim.*, 1913, [iv], 13, 236—240. Compare Wahl and Meyer, A., 1908, i, 368; Wahl, *ibid.*, 1909, i, 260).—The authors have condensed *o*-, *m*-, and *p*-methoxyphenyl-*isooxazolone* with a number of aldehydes, and have thus prepared the following substances : 3-o-*methoxyphenyl-4-benzylideneisooxazolone*, yellow leaflets, m. p. 150°; 3-m-*methoxyphenyl-4-benzylideneisooxazolone*, yellow needles, m. p. 110°; 3-p-*methoxyphenyl-4-benzylideneisooxazolone*, yellow leaflets, m. p. 170°; 3-o-*methoxyphenyl-4-anisylideneisooxazolone*, pale yellow, m. p. 154°; 3-m-*methoxyphenyl-4-anisylideneisooxazolone*, yellow crystals, m. p. 164°; 3-p-*methoxyphenyl-4-anisylideneisooxazolone*, pale yellow leaflets, m. p. 165°; 3-o-*methoxyphenyl-4-cinnamylideneiso-oxazolone*, orange-yellow, m. p. 163°; 3-m-*methoxyphenyl-4-cinnamyli-deneisooxazolone*, orange-yellow, m. p. 146—147°; 3-p-*methoxyphenyl-4 cinnamylideneisooxazolone*, orange needles, m. p. 163°; 3-o-*methoxy-phenyl-4-furfurylideneisooxazolone*, yellow crystals, m. p. 171—172°; 3-p-*methoxyphenyl-4-furfurylideneisooxazolone*, yellow needles, m. p. 141—142°; 3-o-*methoxyphenyl-4-p-dimethylaminobenzylideneisooxazolone*, red needles, m. p. 190°; 3-m-*methoxyphenyl-4-p-dimethylaminobenzyli-deneisooxazolene*, red needles, m. p. 140°; 3-p-*methoxyphenyl-4-p-di-methylaminobenzylideneisooxazolone*, red leaflets, m. p. 192°; 3-p-*methoxy-phenyl-4-o-hydroxybenzylideneisooxazolone*, yellow leaflets, m. p. 195°; 3-o-*methoxyphenyl-4-p-hydroxybenzylideneisooxazolone*, orange-yellow, m. p. 218°; 3-m-*methoxyphenyl-4-p-hydroxybenzylideneisooxazolone*, yellow leaflets, m. p. 215°; 3-p-*methoxyphenyl-4-p-hydroxybenzylideneisooxazolone*, golden-yellow needles, m. p. 204—205°; 3-o-*methoxyphenyl-4 p-hydroxy-m-methoxybenzylideneisooxazolone*, yellow crystals, m. p. 168°; 3-m-*methoxyphenyl-4-p-hydroxy-m-methoxybenzylideneisooxazolone*, orange-yellow crystals, m. p. 203°; 3-p-*methoxyphenyl-4-p-hydroxy-m-methoxy-benzylideneisooxazolone*, yellow crystals, m. p. 199°; 3-o-*methoxyphenyl-*

4-mp-*dihydroxybenzylidene*isooxazolone, orange crystals, m. p. 209°;
3-m-*methoxyphenyl*-4-mp-*dihydroxybenzylidene*isooxazolone, orange-red
needles, m. p. 184°; 3-p-*methoxyphenyl*-4-mp-*dihydroxybenzylidene*iso-
oxazolone, orange crystals, m. p. 193°; with o-vanillin, the 3-o- and
p-methoxyphenyl*isooxazolones* form yellow *leaflets*, m. p. 195°, and
orange-yellow *leaflets*, m. p. 208°, respectively, whilst with resorcyl
aldehyde, 3-o-, m- and p-methoxyphenyl*isooxazolones* yield orange-
yellow *crystals*, m. p. 235°, orange-yellow *crystals*, m. p. 240°, and
yellow *crystals*, m. p. 209°, respectively. The phenolic derivatives
dissolve in alkali, forming solutions in which the colour varies from
yellow to reddish-violet. Presence of excess of alkali rapidly discharges
these colorations, yielding colourless solutions from which acids
re-precipitate the original substance. The action of excess of alkali
probably causes a rupture of the lactonic grouping according to the
scheme:

$$O<\begin{matrix}CO\cdot C\colon CH\cdot R\\ N=C\cdot C_6H_4\cdot OCH_3\end{matrix} \quad \underset{HCl}{\overset{NaOH}{\rightleftarrows}} \quad \begin{matrix}CO_2Na\cdot C\colon CH\cdot R\\ HO\cdot N=C\cdot C_6H_4\cdot OCH_3\end{matrix}\cdot$$

The three methoxyphenyl*isooxazolones* have been condensed with
5-bromoisatin chloride, yielding the three 3-*methoxyphenyl*isooxazolone-
5-*bromo-2-indoles*,

$$\begin{matrix}N\colon C\cdot C_6H_4\cdot OCH_3\\ O\underline{\quad\quad} CO\end{matrix}>C\colon C<\begin{matrix}NH\\ CO\end{matrix}>C_6H_3Br,$$ the proper-

ties of which are similar to those of the previously described indigoid
dyes derived from the three methoxyphenyl*isooxazolones* and isatin
chloride. If, however, sodium hyposulphite is added to their solution
in alkali, the yellow colour of the latter persists. Addition of acid
causes the formation of a flocculent, yellow *precipitate*. The latter
dissolves in alcohol, forming a red solution, the colour of which deepens
on addition of an oxidising agent, the initial dye being ultimately
formed. The yellow precipitate appears to be the leuco-derivative
of the dye. It presents no marked affinity for the textile fibres.

H. W.

**Action of Acetic Anhydride on some Benzylideneanthranilic
Acids. II.** John B. Ekeley and Stiles Clinton (*J. Amer. Chem.
Soc.*, 1913, **35**, 282—284).—Ekeley and Dean (A., 1912, i, 211) have
shown that a series of oxazines can be obtained by the action of acetic
anhydride on benzylideneanthranilic acids. The reaction seems to be
of general application, and further compounds are now described.

Protocatechuylideneanthranilic acid, m. p. 204°, obtained by the
condensation of protocatechualdehyde with anthranilic acid, forms
orange-red crystals, and is converted by acetic anhydride into 4-*acetyl*-
3-(3′ : 4′)*dihydroxyphenyldihydro*-2 : 4-*benzoxazine*-1-*one*,

$$C_6H_4<\begin{matrix}CO\underline{\quad}O\\ NAc\cdot CH\cdot C_6H_3(OH)_2\end{matrix},$$
m. p. 121°. *Bromosalicylideneanthranilic acid*, m. p. 198°, crystallises in
yellow needles, and furnishes 4-*acetyl*-3-(4′ : 2′-)*bromohydroxyphenyldi-
hydro*-2.4-*benzoxazine*-1-*one*, m. p. 170°. o-*Nitrobenzylideneanthranilic
acid*, m. p. 67°, forms straw-coloured needles, and yields 4-*acetyl*-3-o-
nitrophenyldihydro-2:4-*benzoxazine*-1-*one*, m. p. 167·5°. o-*Methoxybenzyl-
ideneanthranilic acid*, m. p. 122°, gives 4-*acetyl*-3-o-*methoxyphenyldihydro*-
2:4-*benzoxazine*-1-*one*, m. p. 165°. *Resorcylideneanthranilic acid* begins to

decompose at about 150°; *4-acetyl-3-(1:3)-dihydroxyphenyldihydro-2:4-benzoxazine-1-one* has m. p. 192°. p-*Dimethylaminobenzylidene-anthranilic acid*, m. p. 176°, yields *4-acetyl-3-p-dimethylaminophenyl-dihydro-2:4-benzoxazine-1-one*, m. p. 162°.　　　　　　　　　E. G

A Gelatinous Mercury Salt of an Organic Sulphonic Acid.
W. DOHLE and BERTHOLD RASSOW (*Zeitsch. Chem Ind. Kolloide*, 1913, 12, 71—74).—By the action of fuming sulphuric acid on benzothiazole-methenesulphide, a monosulphonic acid of the composition :

$$C_8H_6NS_2 \cdot SO_3H$$
is obtained. When aqueous solutions of the potassium salt and of mercuric chloride are mixed together, a yellow solution is obtained, which, sooner or later, depending on the concentration, solidifies to a jelly. The jelly-forming substance is the normal mercuric salt, and its activity is such, that even in $N/100$-solution it is capable of producing a jelly at the ordinary temperature. The mercury salt is unstable, and the jellies sooner or later become cloudy in consequence of the formation of the basic salt, $Hg(C_8H_6NS_2 \cdot SO_3)_2, HgO$, which separates out in the form of very small crystals. The stability of the jellies increases with the concentration of the mercury salt and those prepared from $N/5$-solutions of the potassium salt and mercuric chloride can be kept for some time before they begin to exhibit opalescence as a result of the initial precipitation of the basic salt.

The colloidal mercury salt is coagulated by electrolytes and alcohol, the coagulum being converted into the crystalline basic salt on contact with water.

From the examination of freshly prepared solutions of the mercury salt, it has been found that the viscosity increases with time, the rate of increase varying very considerably from one solution to another even when the conditions under which the solutions were prepared, were exactly the same. Most electrolytes increase the viscosity, but potassium iodide increases it to a remarkable extent.　　　　H. M. D.

Aromatic ψ-Thiocarbamides and Orthothiocarbonic Esters.
FRITZ ARNDT (*Annalen*, 1913, 396, 1—22. Compare A., 1911, i, 918).—*Phenyl-ψ-thiocarbamide*, $NH:C(NH_2) \cdot SPh$, m. p. 96—97° (decomp.), glistening needles, prepared from phenyl mercaptan and cyanamide, forms a sparingly soluble *nitrate-sulphate*,

$$3C_7H_8N_2S, H_2SO_4, HNO_3,$$
m. p. 206° (decomp.), which, however, is distinctly more soluble than the nitrate-sulphate of p-tolyl-ψ-thiocarbamide (*loc. cit.*) ; in fact, the salts of phenyl-ψ-thiocarbamide are much more soluble than those of the p-tolyl homologue. p-*Chlorophenyl-ψ-thiocarbamide*,

$$NH:C(NH_2) \cdot S \cdot C_6H_4Cl,$$
forms a *nitrate-sulphate*, $3C_7H_7N_2SCl, H_2SO_4, HNO_3$, m. p. 222° (decomp.).

The substance previously described as nitroso-p-tolyl-ψ-thiocarbamide (*loc. cit.*) is now shown to be the p-tolyl-ψ-carbamide salt of *dinitroso* p-*tolyl-ψ-thiocarbamide*, $OH \cdot N:N \cdot O(SC_7H_7):N \cdot NO$. The salt is decomposed by cold glacial acetic acid into nitrogen and p-tolyl thiocyanate, and by cold concentrated hydrochloric acid into nitrous acid and p-tolyl-ψ-thiocarbamide. The yellow substance obtained by

its decomposition by boiling methyl alcohol receives the constitution $C_7H_7S\cdot CO\cdot N\!:\!NOH$, since it yields p-tolylthiocyanate and mercaptan by treatment with concentrated hydrochloric acid. By gradually adding the p-tolyl-ψ-thiocarbamide salt of dinitroso-p-tolyl-ψ-thiocarbamide to a gently boiling methyl-alcoholic solution of potassium acetate (saturated in the cold), the *potassium* salt,

$$C_8H_7O_2N_4SK,H_2O,$$
of the dinitroso-derivative is obtained. It crystallises in glistening needles, yields the *calcium*, *barium*, and *ferric* salts by double decomposition, and the *benzamidine* salt, white leaflets, by treatment with aqueous benzamidine hydrochloride, and by the action of dilute acetic acid yields the free dinitroso-compound, which, however, instantly decomposes into nitrous acid and *nitroso-p-tolyl-ψ-thiocarbamide*,

$$C_7H_7S\cdot C(\!:\!NH)\cdot N\!:\!N\cdot OH,$$

decomp. 115—120°, golden-yellow leaflets. The latter yields nitrous acid and p-tolyl-ψ-thiocarbamide by treatment with concentrated hydrochloric acid, and nitrogen and p-tolyl thiocyanate with warm glacial acetic acid. By treatment with sodium nitrite and hydrochloric acid, phenyl-ψ-thiocarbamide and p-chlorophenyl-ψ-thiocarbamide each yield ψ-thiocarbamide salts of the dinitroso-ψ-thiocarbamide.

As mentioned previously (*loc. cit.*), p-tolyl *ortho*-thiocarbonate is obtained by treating a methyl-alcoholic solution of the p-tolyl-ψ-thiocarbamide salt of dinitroso-p-tolyl-ψ-thiocarbamide with aqueous ammonia. This reaction could not be explained when the p-tolyl-ψ-thiocarbamide salt was considered to be a nitroso-compound. Its course is now clear. The ammonia liberates p-tolyl-ψ-thiocarbamide and converts it into p-tolyl mercaptan, which then reacts with the dinitroso-compound (or its ammonium salt) in accordance with the equation: $C_7H_7S\cdot C(\!:\!N\cdot NO)\cdot N\!:\!N\cdot OH + 3C_7H_7\cdot SH = C(SC_7H_7)_4 + 2N_2 + 2H_2O$. The orthothiocarbonate is also obtained by treating a methyl-alcoholic solution of the p-tolyl-ψ-thiocarbamide salt or the potassium salt of dinitroso-p-tolyl-ψ-thiocarbamide directly with p-tolyl mercaptan.

Phenyl orthothiocarbonate, $C(SPh)_4$, m. p. 159°, small leaflets, and p-*chlorophenyl orthothiocarbonate*, $C(S\cdot C_6H_4Cl)_4$, m. p. 212—213°, are prepared by methods similar to the preceding. p-*Chlorophenyl orthothioformate*, $CH(S\cdot C_6H_4Cl)_3$, m. p. 111—112°, almost colourless leaflets, is obtained by boiling p-chlorophenyl mercaptan in aqueous sodium hydroxide with an excess of chloroform. *Phenyl tri-p-chlorophenyl orthothiocarbonate*, $SPh\cdot C(S\cdot C_6H_4Cl)_3$, small, white leaflets, m. p. about 191°, obtained by warming potassium dinitrosophenyl-ψ-thiocarbamide and the calculated amount of p-chlorophenyl mercaptan in methyl alcohol, is converted by crystallisation from acetic acid into a mixture of the tetraphenyl and the tetra-p-chlorophenyl esters of orthothiocarbonic acid; the latter has been isolated. *Tri-p-chlorophenyl-p-tolyl orthothiocarbonate*, m. p. about 193°, is prepared in a similar manner, and also tends to change to the unmixed esters. By reduction with boiling glacial acetic acid and zinc dust, it is converted into *di-p-chlorophenyl-p-tolyl orthothioformate*, $C_7H_7S\cdot CH(S\cdot C_6H_4Cl)_2$, m. p. 96—97°, white leaflets, which is not changed by crystallisation from glacial acetic acid.   C. S.

Preparation of 6-Aminodiarylamino- and 7-Aminodiaryl-amino-1-naphthol-3-sulphonic Acids with their Derivatives. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254510).— Numerous compounds obtained by the condensation of aromatic benzenoid amines with aminonaphthols in the presence of sodium hydrogen sulphite have been previously described (A., 1905, i, 585), and the reaction has now been extended to the diphenyl series.
4'-*Amino*-7-*diphenylamino*-1-*naphthol*-3-*sulphonic acid* (annexed formula) is obtained when 1 : 7-dihydroxynaphthalene-3-sulphonic acid (240 parts) is boiled during forty-eight hours with benzidine (184 parts) and an aqueous solution of sodium hydrogen sulphite (2400 parts); the *sodium* salt forms grey leaflets.

The following compounds are also described : 3'-*sulpho*-4'-*amino*-6-*diphenylamino*-1-*naphthol*-3-*sulphonic acid* ; 3'-*sulpho*-4'-*amino*-7-*diphenylamino*-1-*naphthol*-3-*sulphonic acid*, from 7-amino-1-naphthol-3-sulphonic acid with benzidinesulphonic acid ; 4'-*amino*-6-*diphenyl-amino*-1-*naphthol*-3-*sulphonic acid*, from benzidine with 1 : 7-dihydroxy-naphthalene-3-sulphonic acid ; and the *compound*, from 7-amino-1-naphthol-3-sulphonic acid with benzidinesulphonic acid and a mixture of ammonium and sodium hydrogen sulphites ; the *sodium* salt forms glistening, grey leaflets.   F. M. G. M.

Catalytic Decomposition of Phenylhydrazine by Cuprous Salts. ALEXANDER E. ARBUZOV and V. M. TICHVINSKI (*J. Russ. Phys. Chem Soc*, 1913, **45**, 69—70).—When heated with cuprous chloride, bromide or iodide, phenylhydrazine undergoes catalytic decomposition according to the equation :

$$3NHPh\cdot NH_2 + CuX = 3NH_2Ph + N_2 + NH_3 + CuX$$

(compare Struthers, P., 1905, 95). In all cases, an unstable intermediate compound is formed, that given by the iodide having the composition $CuI,2NHPh\cdot NH_2$. Cuprous chloride is the most effective and the iodide the least so.   T. H. P.

A Process for the Preparation of New Colouring Matters and its Application. BRONISLAW PAWLEWSKI (*Bull. Soc. ind. Mulhouse*, 1912, **82**, 682—683).—When aniline in acid or alcoholic solution is oxidised at 50—60° with ammonium persulphate, a black *dye* is obtained, which is considered to be bisimino-*p*-benzoquinone,

$$O{:}C_6H_4{:}N\cdot N{:}C_6H_4{:}O.$$
By changing the conditions, other brown or black anilinoquinones are formed. Similar colouring matters containing oxygen have been prepared from *m*-phenylenediamine, *o*-dianisidine, and benzylaniline. They are easily fixed by cotton, linen or silk, with or without the aid of mordants.   J. C. W.

Preparation of 1-*p*-Bromo-4-iodophenyl- and of 4-Bromo-1-*p*-iodophenyl-2 : 3 dimethyl-5-pyrazolone. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254487).—The introduction of bromine and iodine into the molecule of 1-phenyl-2 : 3-dimethyl-5-pyrazolone confers on it a markedly increased therapeutic activity.

1-p-*Bromo-4-iodophenyl*-2 : 3-*dimethyl-5-pyrazolone* (annexed formula), colourless crystals, m. p. 163°, is obtained when a benzene solution of *p*-bromophenyl-2 : 3-dimethyl-5-pyrazolone (A., 1900, i, 695) is treated with finely powdered iodine and heated at 50—60° during two hours, whilst 4-*bromo*-1-p-*iodophenyl* 2 : 3-*dimethyl-5-pyrazolone*, pale yellow leaflets, m. p. 170°, is prepared by the bromination of 1-*p*-iodophenyl-2 : 3-dimethyl-5-pyrazolone (A., 1907, i, 84).   F. M. G. M.
Hydantoins. XXI. Action of Ammonium and Potassium Thiocyanates on α-Amino-acids. TREAT B. JOHNSON and BEN H. NICOLET (*Amer. Chem. J.*, 1913, 49, 197—204).—In an earlier paper (this vol., i, 203), it has been pointed out that ammonium and potassium thiocyanates behave somewhat differently towards α-amino-acids. It has now been found that both salts combine with the acids to form the same thiohydantoins, but that the best yields are obtained by means of the ammonium salt.

When asparagine is treated with ammonium thiocyanate, 2-thio-3-acetylhydantoin-4-acetamide (Johnson and Guest, A., 1912, i, 807) is obtained in a yield amounting to 50% of the theoretical, whilst with the potassium salt a yield of only 6% is obtained.

Phenylalanine gives with ammonium thiocyanate a 94% yield of 2-thio-3-acetyl-4-benzylhydantoin, m. p. 170° (not 257° as stated by Johnson and O'Brien, A., 1912, i, 806); a somewhat smaller yield is obtained by the use of the potassium salt.

By the action of ammonium thiocyanate on tyrosine, a 94% yield is obtained of 2-*thio*-4-p-*hydroxybenzylhydantoin*,

$$\begin{array}{c}NH \cdot CO \\ CS \cdot NH\end{array}\!\!\!\!> OH \cdot CH_2 \cdot C_6H_4 \cdot OH,$$
m. p. 211°, which forms pale yellow needles ; if potassium thiocyanate is employed, only a very small yield is obtained.

2-Thio-3-benzoylhydantoin (Johnson and Nicolet, A., 1912, i, 53) is obtained in 85—88% yield by the action of ammonium thiocyanate on hippuric acid, but in not more than 50% yield by the action of the potassium salt.

In the case of alanine, an excellent yield of 2-thiol-3-acetyl-4-methylhydantoin (Johnson, A., 1912, i, 390) is obtained with ammonium thiocyanate, but only about 34% with the potassium salt.

The thiohydantoin of pyrrolidonecarboxylic acid (Johnson and Guest, A., 1912, i, 317) is readily obtained in good yield by means of ammonium thiocyanate, but only in small amount by the action of the potassium salt.   E. G.

The Reactivity of the β-Unsubstituted Pyrrole Ring. III. Action of Cyanogen Bromide and Pyridine on Indoles. WALTER KÖNIG and R. SCHRECKENBACH (*J. pr. Chem.*, 1913, [ii], **87**, 241—257). —In view of the parallelism, previously shown to exist (A., 1911, i, 808), in the reactivity of primary aromatic amines and phenols on the one hand, and of 3-unsubstituted indole derivatives on the other, the author has examined the behaviour of the latter compounds toward pyridine and cyanogen bromide, and finds that they yield dyes which have the general formula :

$$NH{<}^{C_6H_4}_{OR}{>}C{\cdot}CH{:}CH{\cdot}CH{:}CH{\cdot}CH{:}C{<}^{C_6H_4}_{OR}{>}NHX,$$
and are, therefore, closely related to the pyridine dyes derived from aromatic amines.

α-2-Methylindyl-ε-2-methylindolidene-Δαγ-pentadiene hydrobromide,

$$NH{<}^{C_6H_4}_{CMe}{>}C{\cdot}CH{:}CH{\cdot}CH{:}CH{\cdot}CH{:}C{<}^{C_6H_4}_{CMe}{>}NHBr,$$ is obtained in

lustrous, golden leaflets by the action of hot acetone on its additive *compound*, $C_{23}H_{21}N_2Br,C_5H_5N,HBr$, with pyridine hydrobromide. The latter compound separates in green needles by the successive addition of pyridine and cyanogen bromide in ethereal solution to 2-methylindole, dissolved in methyl alcohol. The *dihydrobromide*, prepared by warming the monohydrobromide with acetone and hydrobromic acid, crystallises in lustrous, silky, bluish-green needles.

On treatment with aqueous sodium hydroxide and methyl alcohol, the hydrobromide yields the *dye-base*, $C_{23}H_{20}N_2$. This forms bluish-black needles, and is converted at 220° into a yellow *substance*, m. p. 265°, which probably has the same composition as the original dye-base, yields a *phenylhydrazone* (decomp. 160—170°), and when heated at 160° under diminished pressure decomposes, yielding 2-methylindole. The dye-base reacts with phenylhydrazine in alcoholic solution, yielding 2-methylindole and the *phenylhydrazone*,

$$NH{<}^{C_6H_4}_{CMe}{>}C{\cdot}CH{:}CH{\cdot}CH{:}CH{\cdot}CH{:}N{\cdot}NHPh,$$
which forms an amorphous, light yellow powder (decomp. 170—180°) containing alcohol (1 mol.).

On treatment with dry hydrogen chloride, the dye-base yields a *hydrochloride*, $C_{23}H_{21}N_2Cl$; the *perchlorate*, $C_{23}H_{21}O_4N_2Cl$, forms small, compact, green crystals having a golden lustre, and crystallises with methyl alcohol in long, slender, bluish-green needles.

α-Indyl-ε-indolidene-Δαγ-pentadiene hydrobromide, $C_{21}H_{17}N_2Br$, prepared from indole, cyanogen bromide, and pyridine in methyl alcoholic solution, forms a microcrystalline, dark blue powder, containing pyridine (1 mol.).

α-2:4-Dimethylindyl-ε-2:4-dimethylindolidene-Δαγ-pentadiene hydrobromide, prepared from 2:4-dimethylindole, yields on treatment with aqueous sodium hydroxide and methyl alcohol the *dye-base*, $C_{25}H_{24}N_2$, which forms microcrystalline, bluish-black needles ; a *dihydrobromide* and a *perchlorate*, crystallising in green leaflets of a golden lustre, are also described.

The action of cyanogen bromide and pyridine on phloroglucinol and

resorcinol gives rise to blue pyridine dyes, which, however, are too unstable to be isolated. F. B.

[Preparation of 4-Chloro-5-bromoisatin.] KALLE & Co. (D.R.-P. 254468).—*4-Chloroisatin*, a yellow, crystalline powder, m. p. 254°, is prepared by treating a cooled acetic-chromic acid solution of 4 : 4'-dichloroindigotin with concentrated nitric acid ; when warmed with bromine (in acetic acid solution) it gives rise to *4-chloro-5-bromoisatin*, red needles, m. p. 255°, which on treatment with phosphorus pentachloride furnishes *4-chloro-5-bromoisatin chloride*, brown needles, m. p. 278° ; the corresponding anilide was also prepared.

F. M. G. M.

Preparation of 5 : 6 : 5' : 6'-Tetrachloroindigotin. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254467).—*4 :5-Dichloro-2-nitrobenzaldehyde*, yellow prisms, m. p. 73°, is prepared by the nitration of 4 : 5-dichlorobenzaldehyde ; this when condensed with acetone in the presence of sodium hydrogen sulphite furnishes *dichloronitrophenyl-lactyl ketone*, m. p. 116°, which is readily converted by known methods into 5 : 6 : 5' : 6'-*tetrachloroindigotin*, a substance possessing valuable tinctorial properties. F. M. G. M.

Preparation of Dinitro-1 : 1'-dianthrimide. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254186).—The nitration of dianthrimide (which has previously been described) takes place more smoothly and yields a definite characteristic product when carried out in the presence of boric acid.

1 : 1'-Dianthrimide (100 parts) and boric acid (65 parts) are dissolved in 1000 parts of concentrated sulphuric acid, treated at 5—10° with 27% nitric acid (122 parts), and left during two to three days at the ordinary temperature, when about 87% of the 4 : 4'-dinitro-1 : 1'-dianthrimide separates in glistening, coppery crystals. The m. p. is above 300°, and it is identical with the compound previously obtained by condensing 4-nitro-1-amino- with 4-chloro-1-amino-anthraquinone ; on reduction it furnishes 4 : 4'-diamino-1 : 1'-dianthrimide.

F. M. G. M.

Preparation of ω-Methylsulphites of Substituted Amino-arylpyrazolones. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254711).—Compounds having valuable therapeutic properties are obtained when the substituted 4-amino-1-phenyl-2 : 3-dimethyl-5-pyrazolones are heated with formaldehyde and sodium hydrogen sulphite ; *compounds* obtained in this manner from the following pyrazolones have now been prepared. From 4-amino-1-phenyl-2 : 3-dimethyl-5-pyrazolone, sintering and decomposing at 231—233° ; from 4-amino-1-*p*-tolyl-2 : 3-dimethyl-5-pyrazolone, sintering at 120°, decomposing at 125° ; from 1-*p*-aminophenyl-2 : 3-dimethyl-5-pyrazolone, isolated as its hygroscopic, crystalline *sodium* salt ; from 1-*p*-amino-phenyl-2 : 3 : 4-trimethyl-5-pyrazolone, also isolated as a crystalline

sodium salt; from 4-amino-1-*p*-ethoxyphenyl-2:3-dimethyl-5-pyrazolone, m. p. 113—115°, decomp. at 133—135°. The foregoing *4-amino-p-ethoxyphenyl-2 : 3-dimethyl-5-pyrazolone*, m. p. 132—133°, is obtained by the reduction of 4-nitroso-*p*-ethoxy-2 : 3-dimethyl-5-pyrazolone.

F. M. G. M.

Pyrimidines. LIX. Barbituryl- and 2-Thiobarbituryl-5-acetic Acids. TREAT B. JOHNSON and EDWARD F. KOHMANN (*Amer. Chem. J.*, 1913, **49**, 184—197).—An account is given of experiments undertaken with a view to the preparation of compounds containing condensed pyrimidine and pyrrole nuclei, and corresponding with the indoles and pyrindoles (Perkin and Robinson, T., 1912, **101**, 1787). Compounds of this new class are termed 1:6:8-, 1:5:7-, and 2:5:7-pyrimazoles (annexed formulæ).
A 1:6:8-pyrimazole has already been obtained by heating ethyl 6-chloro-2-ethylthiolpyrimidine-5-acetate with alcoholic ammonia (A., 1911, i, 575); this compound, previously termed 2-ethylthiol-5:6-*a*-pyrrolidone-pyrimidine, is now designated 2-keto-7-ethylthiol-1:6:8-pyrimazole.

When ethyl ethane-*aaβ*-tricarboxylate is treated with carbamide in the presence of sodium ethoxide, the *sodium* salt of barbituryl-5-acetamide is obtained, which crystallises with $4H_2O$. *Barbituryl-5-acetamide*,

$$CO{<}^{NH \cdot CO}_{NH \cdot CO}{>}CH \cdot CH_2 \cdot CO \cdot NH_2,$$
m. p. 258—261° (decomp.), crystallises in needles. *Barbituryl-5-acetic acid*, $CO{<}^{NH \cdot CO}_{NH \cdot CO}{>}CH \cdot CH_2 \cdot CO_2H$, obtained by the action of 20% hydrochloric acid on the sodium salt of the amide, separates in plates, becomes charred at 230°, and decomposes at 250°. An attempt to condense the amide to a 1:6:8-pyrimazole by the action of phosphoryl chloride on its sodium salt was not successful.

Thiobarbituryl-5-acetamide, $CS{<}^{NH \cdot CO}_{NH \cdot CO}{>}CH \cdot CH_2 \cdot CO \cdot NH_2, H_2O$,

prepared by the condensation of thiocarbamide with ethyl ethane-*aaβ*-tricarboxylate, crystallises in needles and decomposes at 272°; the *sodium* salt forms long, colourless prisms. *Thiobarbituryl-5-acetic acid*, $CS{<}^{NH \cdot CO}_{NH \cdot CO}{>}CH \cdot CH_2 \cdot CO_2H, 2H_2O$, crystallises in needles and decomposes above 230°.

Ethyl cyanosuccinate condenses with carbamide with formation of a pyrimidine. The reaction does not take place smoothly, and only small yields of condensation products are obtained. In one experiment, barbituryl 5-acetic acid was pro-

produced, together with 2 : 5 : 7-*triketo*-1 : 6 : 8-*pyrimazole* (formula I), which forms a brown powder and does not melt below 320°. In another experiment, barbituryl-5-acetic acid and 4-*iminobarbituryl-5-acetic acid*,
$$CO\underset{NH\cdot C(:NH)}{\overset{NH----CO}{<}}>CH\cdot CH_2\cdot CO_2H,$$
were isolated; the latter substance is a brown powder, and does not melt below 338°.   E. G.

Preparation of Azimino-[Triazole]-compounds in the Anthraquinone Series. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254745).—The azimino-compounds having the general formula $A<\underset{-N}{\overset{NR}{}}>N$, where A is anthraquinone and R hydrogen, alkyl or aryl groups, and prepared by the action of nitrous acid on *o*-diamino-anthraquinones, are of technical value for the preparation of dyes. The preparation of the following *compounds* is described: From 1 : 2-diaminoanthraquinone, needles; from 2 : 3-diaminoanthra-quinone, and from 1-*p*-tolylamino-2-amino-3-bromoanthraquinone, citron-yellow needles. The tinctorial properties of these compounds are enhanced by the introduction of halogens into the molecule.

F. M. G. M.

Polymeric Indoles. K. KELLER (*Ber.*, 1913, **46**, 726—733).— The high-boiling residue obtained in the distillation of practically pure indole consists of a trimeride, *tri-indole*, which after recrystalli-sation from benzene can be obtained in colourless crystals, m. p. 167°. The polymerisation can be better effected by heating indole with an aqueous solution of metaphosphoric acid. When distilled in a vacuum, tri-indole decomposes completely into indole; it gives a *monoacetyl* derivative, colourless crystals, m. p. 202°, and a *monobenzoyl* deriv-ative, colourless, crystalline powder, m. p. 207°. These acyl compounds are remarkably resistant to alkalis. When benzoyltri-indole is heated in a vacuum, indole distils away, leaving a residue of *benzoyldi-indole*, colourless needles, m. p. 198°; this resisted all attempts at acetylation and hydrolysis. The easiest method for the preparation of benzoyl-tri-indole is by boiling together a benzene solution of indole with anhydrous sodium carbonate and benzoyl chloride, whilst a slow current of hydrogen chloride is passed through the mixture; the yield is then 90% of the indole taken.

The action of hydrogen chloride on a solution of indole in benzene yields a colourless salt of composition

$$(C_8H_7N)_2,HCl,$$
presumably *di-indole hydrochloride*, but it was not found possible to isolate the corresponding base in a pure state.

From a consideration of the behaviour of the above tri-indole derivatives, the annexed structure is suggested for the base, the reactive indole nucleus being that on the left; this differs from the remaining two by being attached to the rest of the molecule at carbon atoms which are each adjacent to nitrogen atoms. D. F. T.
Preparation of Formaldehyde Derivatives of Xanthine and its Substitution Products. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 254488).—When xanthine, its derivatives, or the purine bases are gently heated in aqueous or hydrochloric acid solution with formaldehyde (or its generators), they furnish *compounds* of marked therapeutic value. The following are described : (1) From 1 : 3-dimethylxanthine and formaldehyde in aqueous solution, contains 14% formaldehyde, m. p. 265° when slowly heated, but if suddenly subjected to a temperature of 165—170°, violent decomposition occurs with regeneration of 1 : 3-dimethylxanthine.

(2) From 3 : 7-dimethylxanthine with paraformaldehyde in fuming hydrochloric acid solution, it forms characteristic needles, contains 14% formaldehyde, and does not melt below 300°.

(3) From xanthine and formaldehyde, contains 32% formaldehyde ; and (4) from 3-methylxanthine contains 16% of formaldehyde. These compounds readily decompose in the organism with elimination of formaldehyde.   F. M. G. M.

The Anomalies in the Solubility of Uric Acid (Colloidal Uric Acid). HEINRICH SCHADE and E. BODEN (*Zeitsch. physiol. Chem.*, 1913, 83, 347—380).—If uric acid is suspended in boiling water, and alkali is then added very slowly until the mixture is just alkaline to phenolphthalein, the acid appears to pass into solution. This solution can be made by one of the following methods to set to a solid gel : (*a*) by the addition of concentrated sodium chloride solution ; (*b*) by addition of other salt solutions, such as ammonium sulphate, which are ordinarily employed for the precipitation of colloids ; (*c*) by addition of alcohol, and (*d*) by rapid cooling. The same phenomenon can be produced when the acid is neutralised by ammonia, lithium, sodium and potassium hydroxides, by the alkaline earths, and even ferric hydroxide. The appearance of the gel thus produced is described in great detail, and also the phenomena of its gradual transformation into the ordinary crystalline form. The colloid appears to be a supersaturated uric acid solution, in which the uric acid forms an adsorption compound with the alkali, which causes it to retain the colloidal form, and this adsorption compound appears to be a preliminary stage in the formation of the true chemical crystalline compound. The view here advanced can explain certain anomalies, to which Bechhold and Ziegler have called attention as regards the solubility of uric acid in serum.   S. B. S.

Purines. VIII. 2 : 8-Dihydroxy-1 : 9-dimethylpurine and 2-Hydroxy-6 : 9-dimethylpurine. CARL O. JOHNS (*J. Biol. Chem.*, 1913, 14, 1—7).—2 : 8-Dihydroxy-1 : 9-dimethylpurine is synthesised as follows : the potassium salt of 5-nitro-6-methylamino-2-hydroxypyrimidine (Johns, A., 1911, i, 506) when heated with methyliodide gives 5-*nitro-6-methylamino-2-hydroxy-3-methylpyrimidine*, the constitution of which is established by heating the methylated product with sulphuric acid, when 5-nitro-2 : 6-dihydroxy-3-methylpyrimidine (Behrend and Thurm, A., 1902, i, 833) is obtained.

On reducing the methylated product with freshly precipitated

ferrous hydroxide, it is converted into *5-amino 6-methylamino-2-oxy-3-methylpyrimidine*, $N<^{C(NHMe)\cdot C\cdot NH_2}_{CO\cdot NMe-CH}$. This is very soluble and purified only with difficulty. The crude base was accordingly heated with carbamide and converted into *2 : 8-dioxy-1 : 9-dimethylpurine*, $^{NMe\cdot CH:C\cdot NH}_{CO-N:C\cdot NMe}>CO$.

By heating the potassium salt of acetyl-5 : 6-diamino-2-oxy-4-methylpyrimidine, *2-oxy-6 : 9-dimethylpurine*,

$$^{N:CMe-C\cdot NH}_{CO\cdot NH\cdot C-N}>CMe,$$
is obtained.

5-Nitro-6-methylamino-2-oxy-3-methylpyrimidine forms a bulky mass of hair-like crystals, m. p. 203°, to a colourless oil.

The *picrate* of *5-amino-6-methylamino-2-oxy-3-methylpyrimidine* crystallises in long prisms, m. p. 200° (decomp.).

2 : 8-Dioxy-1 : 9-dimethylpurine crystallises in small, irregular plates, which do not melt or char at 320°.

2-Oxy-6 : 8-dimethylpurine separates in small prisms with square ends, which slowly turn brown at 315°; they give a murexide reaction.
E. F. A.

Azomethines and Azo-dyes. CAMILLE G. VERNET (*Arch. Sci. phys. nat.*, 1913, [iv], 35, 148—172).—The azomethines derived from a number of diamines and benzaldehyde or its derivatives are described. In general they are formed quantitatively, the amount isolated depending on the manner in which the condensation is effected and the dilution of the solvents employed.

2-Mononitrobenzidine forms with benzaldehyde a yellowish-brown *compound*, m. p. 157°; with one molecule of *p*-nitrobenzaldehyde the product is red, m. p. 200—201°, with two molecules it is yellow, m. p. 205—206°; with dimethyl-*p*-aminobenzaldehyde it is yellow with an ill-defined melting point; with *o*-vanillin it is red, m. p. 200°·

m-Dinitrobenzidine and *o*-vanillin yield a reddish-brown product.

Benzidinesulphone combines with one molecule of benzaldehyde to a yellow compound, m. p. 259—260°; with *p*-nitrobenzaldehyde to a brown compound, m. p. 302—304°; with dimethyl-*p*-aminobenzaldehyde the compound is yellow, m. p. 318°; with *o*-vanillin it is yellowish-red.

Diaminodiphenylamine and benzaldehyde form a yellow compound, m. p. 184—185°; with *p*-nitrobenzaldehyde the compound is black with a metallic lustre, m. p. 219°; with dimethyl-*p*-aminobenzaldehyde it is very similar, m. p. 222°; with *o*-vanillin it is brick-red, m. p. 207—208°.

3 : 3'-Diaminocarbazole and benzaldehyde yield a yellow substance, m. p. 186°; the product with *p*-nitrobenzaldehyde is red, m. p. 306—307°; with dimethyl-*p*-aminobenzaldehyde it is yellowish-brown, m. p. 266—268°; with *o*-vanillin it is brick-red, m. p. 254—255°.

trans-o-Diaminostilbene and benzaldehyde form a yellow product, m. p. 188°; with *p*-nitrobenzaldehyde it is orange-red, m. p. 228°; with

dimethyl-*p*-aminobenzaldehyde it is yellow, m. p. 227°, and with *o*-vanillin it is red, m. p. 228°.

p-Diaminostilbene yields a yellow compound with benzaldehyde, m. p. 254°; an orange-red compound with *p*-nitrobenzaldehyde, m. p. 242°; a reddish-yellow product with dimethyl-*p*-aminobenzaldehyde, m. p. 233°, and a red product with *o*-vanillin.

These azomethines are all very similar; the nitro-group has a greater effect in intensifying the colour than the substituted amino-group.

Most of the compounds have a normal composition with both amino-groups condensed, but traces of the condensation products with a single molecule of aldehyde are formed at the same time.

A comparison is made of the colours obtained by soaking the material impregnated with sodium-β-naphthoxide in the diazotised solutions of a number of diamines   Whereas benzidine gives a brown, thiobenzidine and benzidinesulphone give reddish-brown shades, mononitrobenzidine gives a red, *m*-dinitrobenzidine an orange, and the *o*-dinitro-derivative a garnet-red. With 2 : 2'- or 3 : 3'-diamino-carbazole the colour is almost black, and *p*-diaminostilbene gives a similar colour. The replacement of an atom of hydrogen by a univalent grouping has more influence on the colour than when two atoms of hydrogen are replaced by a bivalent substituent.

Each of the diamino-bases studied has been coupled with five acid compounds, namely, H-acid, chromotropic acid, Nevile and Winther's acid, resorcinol, and naphthoic acid. The resulting compounds have not been analysed, but were directly utilised for dyeing tests. The colours obtained are detailed in tabular form; they act as substantive colours for cotton, and dye wool from acid solutions.   E. F. A.

Thiophenols. III. *pp'*-**Azophenyl Methyl- and** *pp'*-**Azophenyl Ethyl-sulphide.** KURT BRAND and ADOLF WIESING (*Ber.*, 1913, **46**, 820—829).—The authors have extended their previous work on *pp'*-azophenyl methyl sulphide (A., 1912, i, 666), and have investigated the corresponding ethyl derivative.

A concentrated aqueous solution of sodium hydroxide and sodium sulphide is gradually added to a boiling alcoholic solution of di-*p*-nitro-diphenyl disulphide. From the cooled reaction mixture, the *sodium* derivative of *p*-nitrophenyl mercaptan, $C_6H_4O_2NSNa,2H_2O$, separates in golden leaflets, which decompose when heated slightly above 100°. The salt dissolves in water, forming a yellow solution, which, on addition of acid, becomes colourless and deposits *p*-nitrophenyl mercaptan. The solution absorbs oxygen with the formation of the disulphide. When warmed with an excess of ethyl bromide, the above sodium salt is transformed into *p*-nitrophenyl ethyl sulphide, m. p. 48° (Blanksma, A., 1902, i, 282, gives 40°; L. Gattermann, 44°). pp'-*Azoxyphenyl ethyl sulphide*, $ON_2(C_6H_4·SEt)_2$, is obtained when a methyl-alcoholic solution of p-nitrophenyl ethyl sulphide is added to a boiling solution of sodium methoxide in methyl alcohol. It forms pale yellow needles, m. p. 97—98°. A sulphinium compound could not be obtained from it by the action of methyl sulphate.

pp'-*Hydrazophenyl ethyl sulphide*, m. p. 76°, is obtained in the same manner as the corresponding methyl compound (*loc. cit.*). In alkaline alcoholic solution it is more readily oxidised by air than the

latter compound, and forms pp'-*azophenyl ethyl sulphide*. m. p. 132°. Treatment with concentrated hydrochloric acid transforms *pp'*-hydrazophenyl ethyl sulphide into p-*aminophenyl ethyl sulphide hydrochloride*, which readily gives up a portion of the hydrogen chloride. The free base, obtained from the hydrochloride by means of ammonia, has b. p. 165°/12 mm. (compare Auwers and Beger, A., 1894, i, 466; Monier-Williams, T., 1906, **89**, 278; Gattermann, A., 1912, i, 986). p-Acetylaminophenyl ethyl sulphide, m. p. 116°, is obtained by shaking an aqueous solution of p-aminophenyl ethyl sulphide hydrochloride with sodium acetate and acetic anhydride, or by boiling the free base with the same reagents.

pp'-Azophenyl ethyl sulphide, $N_2(C_6H_4\cdot SEt)_2$, orange leaflets, m. p. 132°, is obtained by reduction of p-nitrophenyl ethyl sulphide by means of zinc and sodium hydroxide and oxidation of the hot, filtered solution by passing air through it. With mineral acids and strong organic acids it yields intensely blue solutions. The crystalline *hydrochloride* and *trichloroacetate* could not be obtained in the pure state, as they decompose during filtration. The *sulphate*,

$$C_{16}H_{18}N_2S_2,2H_2SO_4,$$
green metallic needles, is obtained by the addition of sulphuric acid to a solution of pp'-azophenyl ethyl sulphide in glacial acetic acid. The following double salts have been obtained : $C_{16}H_{18}N_2S_2,HCl,HgCl_2$, dark violet needles; $C_{16}H_{18}N_2S_2,HCl,FeCl_3$, green leaflets;

$$[C_{16}H_{18}N_2S_2,HCl]_2,FeCl_3,$$
dark green needles; $C_{16}H_{18}N_2S_2,HCl,SnCl_4$, green leaflets;

$$[C_{16}H_{18}N_2S_2,HCl]_2SnCl_4,$$
dark green needles. They were prepared by mixing pp'-azophenyl ethyl sulphide with the metallic chloride in hot glacial acetic acid solution, addition of hydrochloric acid being necessary in the first, third, and fifth cases. They are immediately decomposed by water.

When pp'-azophenyl ethyl sulphide is heated with methyl sulphate and the reaction mixture treated with alcohol, light red crystals, m. p. 158°, are obtained. The aqueous solution yields, on addition of potassium iodide, a sulphinium iodide, m. p. 158—160°, analyses of which gives results from which the authors conclude that the substance is pp'-azophenyldimethylsulphinium iodide. The discrepancy between the m. p. now found and that previously given (174—175°, *loc. cit.*) is attributed to impurity of the specimen.

In extension of their previous work, the authors have prepared the double *salt*, $(C_{14}H_{14}N_2S_2,HCl)_2SnCl_4$, green needles by the action of stannic chloride and hydrochloric acid on a solution of pp'-azophenyl methyl sulphide in glacial acetic acid. They also find that pp'-azophenyldimethylsulphinium methyl sulphate is more conveniently prepared by heating p'-azophenyl methyl sulphide and methyl sulphate for an instant at the boiling point and treatment of the resulting product with alcohol. When this salt is treated with sodium hydroxide, it forms a new *compound*, $C_{18}H_{20}O_8N_2S_4$, investigation of which is not yet completed.   H. W.

The Lakes of Hydroxylic Dyes. RICHARD MÖHLAU (*Ber.*, 1913, **46**, 443—456).—[With JOHANNES MAETZEL]—A brief account is first

given of previous investigations of the compounds of dyes with mordants.

A number of compounds were prepared from various metallic mordants and hydroxylic dyes by precipitation. For the production of simple lakes derived from tervalent metals, solutions of a salt of the metal and of the potassium derivative of the dye were mixed. In order to obtain more complex lakes containing both tervalent and bivalent metals, the tervalent metal derivative was first prepared, and its solution in ammonium hydroxide was then treated with a solution of an equivalent amount of the salt of the bivalent metal (compare Liechti and Suida, A., 1884, 794; 1885, 315; Liebermann and Michaelis, A., 1895, i, 108, 671; Biltz, A., 1906, ii, 78).

The fact that the lakes with the tervalent metals will dissolve readily in ammonium hydroxide indicates that the metallic atom is attached to hydroxylic oxygen, producing phenolic salts; the further introduction of the bivalent metallic atoms is then due to replacement of the hydrogen of the carboxyl or remaining hydroxyl group.

The following lakes of alizarin with tervalent metals were prepared, of the type $Me'''(C_{14}H_7O_4)_3$: *aluminium*, dark brown powder; *chromium*, yellow powder; *iron*, bluish-black powder. These could give calcium derivatives of the general formula $Me_2'''Ca_3(C_{14}H_6O_4)_6$; *aluminium calcium*, violet-brown; *chromium calcium*, deep violet; *iron calcium*, bluish-violet.

Of *p*-nitrobenzeneazosalicylic acid (the acid of alizarin-yellow-R), the following lakes were obtained with tervalent metals of the general formula

$$[NO_2 \cdot C_6H_4 \cdot N_2 \cdot C_6H_3(CO_2H) \cdot O \cdot]_3M''':$$

aluminium, red; *chromium*, brown; *iron*, chocolate. These gave calcium derivatives of the general formula

$$\left(NO_2 \cdot C_6H_4 \cdot N_2 \cdot C_6H_3 {<}_{\;O}^{CO_2}{>}\right)_6 Ca_3Al_2:$$
aluminium calcium, brownish-red; *chromium calcium*, brown; *iron calcium*, brownish-black.

The simple tervalent metallic lakes are more stable towards dilute acid and alkali than the more complex lakes containing two metals; of the latter, the aluminium calcium lakes are most stable and the iron calcium least, and those of alizarin are more stable than the corresponding derivatives of *p*-nitrobenzeneazosalicylic acid.

Benzeneazonaphtholsulphonic acid, $N_2Ph \cdot C_{10}H_5(OH) \cdot SO_3H$, and azo-*o*-toluene-azonaphtholsulphonic acid,

$$C_6H_4Me \cdot N_2 \cdot C_6H_3Me \cdot N_2 \cdot C_{10}H_5(OH) \cdot SO_3H,$$
give unstable *chromium* lakes, brownish-red and claret-red respectively, which are decomposed by dilute alkali or mineral acid; they are consequently regarded as being normal chromium salts and not phenolic derivatives. Complex lakes containing two metals could not be prepared from them.   D. F. T.

Preparation of Acetyl Derivatives of Aminoazobenzene, its Homologues and Analogues. KALLE & Co. (D.R.-P. 253884).— Acetyl derivatives of aminoazobenzene and of the aminoazo-compound prepared from *o*-toluidine have been described previously; it is now

found that by prolonged heating with excess of the reagent, diacetyl derivatives are formed.

Diacetylaminoazotoluene exists in two modifications, long, reddish-yellow needles, m p. 65°, and in crystals, resembling potassium dichromate with m. p. 75°; *diacetylaminoazobenzene* forms long, thin plates, m. p. 103—104°.   F. M. G. M.

Density and Solution Volume of Certain Proteins. (Miss) HARRIETTE CHICK and CHARLES J. MARTIN (*Zeitsch. Chem. Ind. Kolloide*, 1913, **12**, 69—71).—From measurements of the density of casein, crystallised egg-albumin, crystallised serum-albumin and serum-globulin, and of the corresponding solution volumes in aqueous solution, it has been found that the density of the dissolved substance is in all cases greater than that of the free protein, the increase in density varying from 5 to 8%. In the case of serum-albumin and serum-globulin, the solution volume of the protein is independent of the concentration, whereas the contraction, which attends the dissolution of casein, diminishes as the concentration increases.   H. M. D.

The Amount of *l*-Tyrosine in Proteins and the Accuracy of its Estimation. EMIL ABDERHALDEN and DIONYS FUCHS (*Zeitsch. physiol. Chem.*, 1913, **83**, 468—473).—The colorimetric method proposed for the estimation of *l*-tyrosine by Folin and Denis (A., 1912, ii, 1012) is shown to include other amino-acids, and to be untrustworthy. It is possible by crystallisation to separate completely the tyrosine from the products of protein hydrolysis, particularly when the necessary concentration of the liquids is effected under reduced pressure. Most of the published determinations of tyrosine in proteins have been made with insufficient care.   E. F. A.

Colloidal Solutions. I. Certain Metallic Peptonates. EMANUELE PATERNÒ and FLORENTIN MEDIGRECEANU (*Zeitsch. Chem. Ind. Kolloide*, 1913, **12**, 65—68).—Solutions of iron, copper, zinc, and barium peptonate were subjected to prolonged dialysis, and after making up the volumes of the dialysed and residual solutions to the volume of the original solutions, measurements were made of the freezing point, total solids, ash, total nitrogen, and metal for each portion, the data being compared with the corresponding numbers for the original solutions. The observations seem to show that the substances formed by combination of peptone with the metal are, at any rate in the case of iron and copper, of colloidal nature.

H. M. D.

Porphyrinogen. HANS FISCHER and ERICH BARTHOLOMAUS (*Ber.*, 1913, **46**, 511—514).—By the action of a mixture of glacial acetic acid and hydrogen iodide in presence of phosphonium iodide on hæmin in the cold, a colourless, crystalline reduction product, $C_{33}H_{42}O_4N_4$, of high molecular weight is obtained. This is termed porphyrinogen in view of its ready conversion into a red product having the spectroscopic properties of porphyrin.

Sodium methoxide acts on porphyrinogen forming phyllopyrrole;

also a porphyrin, of which the hydrochloride crystallises in centrically grouped needles—probably mesoporphyrin.

On oxidation, porphyrinogen yields methyl ethylmaleinimide and hæmatic acid.

The colourless porphyrinogen behaves as a sensibilising agent when injected into mice exposed to light rays.   E. F. A.

Pepsin. II. SERAFINO DEZANI (*Atti R. Accad. Sci. Torino*, 1913, **48**, 194—200. Compare A., 1910, i, 449).—The pepsin prepared according to the method previously described contains very little chlorine, and the author now finds that by suitable purification this element can be removed almost completely without diminishing the activity of the product. It appears, therefore, that the statements of previous authors that chlorine is a constituent of the substance are incorrect.   R. V. S.

Some Properties of Koji-diastase. G. KITA (*J. Ind. Eng. Chem.*, 1913, **5**, 220—222).—It has been generally assumed that koji (a culture of *Aspergillus oryzae* on steamed rice) contains two different saccharifying enzymes only, namely, amylase and glucase, and that the dextrose present in a liquid saccharified by means of koji is produced by these two enzymes. Comparative experiments on starch and maltose showed, however, that more dextrose was produced from the starch than from maltose, and the author concludes that koji contains a third enzyme which produces dextrose directly from starch without the aid of glucase.

Sodium chloride has a protecting action on koji-diastase when heated, but not on malt-diastase, whilst sodium phosphate, asparagine, and sulphuric acid impair its activity more quickly. The inhibitory action of the sodium chloride depends on the concentration of the diastase; in a dilute solution of the enzyme it is very marked. but not in a concentrated solution. The activity of koji-diastase may be conserved in brine solution for a long period.   T. S. P.

The Reversibility of the Ferment Action of Emulsin. ÉMILE BOURQUELOT and J. COIRRE (*Compt. rend.*, 1913, **156**, 643—646; *J. Pharm. Chim.*, 1913, [vii], **7**, 236—240. Compare A., 1912, i, 928; this vol., i, 212).—The state of equilibrium attained during the synthesis or hydrolysis of a glucoside in alcoholic solution under the influence of emulsin is independent of the amount of emulsin used and depends solely on the proportions of the components of the glucoside in the solution. The action is thus a true reversible reaction, the only effect of varying the concentration of the emulsin being to vary the rate at which equilibrium is reached.   W. G.

Hydrolysis of Amygdalin Under the Influence of Emulsin. LEOPOLD ROSENTHALER (*Arch. Pharm.*, 1913, **251**, 85—89).—Krieble's observation (A., 1912, i, 482) that certain kinds of emulsin react with amygdalin to give *l*-benzaldehydecyanohydrin is confirmed, and a series of experiments has been made to determine the mode of formation of the latter. It is shown that a portion of the benzaldehyde and

hydrogen cyanide which result from the gradual breaking down of amygdalin through mandelonitrile-glucoside and *d*-benzaldehyde-cyanohydrin re-combine to form *i*-benzaldehydecyanohydrin, and if an emulsin such as that from cherry kernels, which is very rich in *d*-oxynitrilase, is used, hydrolysis of the *d*-component of the inactive cyanohydrin ensues, *l*-benzaldehydecyanohydrin being left unaltered.

T. A. H.

Distribution of Emulsin-like Enzymes. LEOPOLD ROSENTHALER (*Arch. Pharm.*, 1913, · 251, 56—84).—The work done in recent years on "emulsin" shows that the latter may include different enzymes depending on its origin (A., 1910, i, 800 ; Armstrong and others, A., 1912, i, 816). The author has, therefore, investigated a large number of plants, particularly those which are known to be cyanogenetic, with a view to ascertaining which of the ordinary components of "almond emulsin" they contain. For this purpose the mixture of enzymes prepared from the plant was mixed with (1) a solution of amygdalin, (2) a mixture of benzaldehyde and hydrocyanic acid (A., 1909, i, 74, 622), and (3) *dl*-benzaldehydecyanohydrin (Feist, A., 1909, i, 589), and the products of the reaction, if any, investigated. The results are described in detail in the original, and are also tabulated for convenience of reference. The following points of special interest are recorded. Enzymes capable of producing asymmetric synthesis or decomposition (reactions 2 and 3 above) are widespread in plants, although less so that those capable of decomposing amygdalin ; this apparent difference may, however, be due to the fact that enzymes of the last-mentioned type are easier to detect by means of their product of reaction. Enzymes of these types may occur in plants which do not yield hydrogen cyanide, but in such cases they are not found in the leaves. These enzymes are not identical with those which decompose amygdalin, since in certain cases, such as *Hydnocarpus Wightiana* seeds, *Pangium edule* seeds, and *Prunus laurocerasus* leaves, negative results were obtained in reaction (1) and positive results with (2) and (3). Similarly, in other cases positive results were obtained for reaction (2) and negative results for reaction (3). An enzyme preparation from the seeds of *Taraktogenos Blumei* furnished in reaction (2) *l*-benzaldehydecyanohydrin instead of the *d*-isomeride furnished by enzymes derived from plants of the order Prunaceæ ; these seeds therefore appear to contain a *l*-oxynitrilese, which may also be present in the flowers of *Achillea millefolium*. No enzyme capable of producing optically active nitriles from ketones and hydrocyanic acid was observed. The enzyme of *Taraktogenos Blumei* is soluble in brine, but not in water. T. A. H.

Oxydases. VI. Tyrosinase is also a Deamidising Enzyme. ROBERT CHODAT and K. SCHWEIZER (*Arch. Sci. phys. nat.*, 1913, 35, 140—147. Compare A., 1912, ii, 399, 611).—It has been shown previously that for the completion of the colour reaction between tyrosinase and *p*-cresol, the presence of an amino-acid is necessary. It is now proved that tyrosinase has a deamidising action on glycine, which it converts into carbon dioxide, ammonia, and formaldehyde.

f f 2

The change is greatly facilitated by the addition of lime water. The formation of formaldehyde is identified by means of Rimini's reagent (phenylhydrazine hydrochloride and potassium ferrocyanide), that of ammonia by means of Nessler's and Trillhat's reagents. The interaction of *p*-cresol, glycine, and tyrosinase is prevented by the addition of calcium hydroxide; in its absence the blue coloration is obtained, and formaldehyde and ammonia are detected amongst the products of reaction.

With alanine and tyrosinase, acetaldehyde is formed in place of formaldehyde. Benzaldehyde is obtained from phenylglycine and tyrosinase.

The presence of formaldehyde in plant tissues does not necessarily indicate photo-synthesis. Attention is drawn to the parallelism between the action of tyrosinase and of hydrogen peroxide on glycine (compare Dakin, A., 1906–1911).   E. F. A.

Preparation of Derivatives of Nitrohydroxy- and Amino-hydroxy-arylarsinic Acids Containing Sulphur. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 253757).—When an alkaline solution of 3-nitro-4-hydroxyphenylarsinic acid is saturated with hydrogen sulphide at the ordinary temperature, it gives rise to *nitrohydroxyphenylarsenosesquisulphide*, $[NO_2 \cdot C_6H_3(OH) \cdot As]_2S_3$, which crystallises from xylene in hard, yellow, nodular crystals, m. p. 160° (about).

Compounds obtained by the action of sodium sulphide on 3-nitro-4-hydroxyphenylarsinic acid (a pale brown powder), of hydrogen sulphide on 3-amino-4-hydroxyphenylarsinic acid, and on its hydrochloride are also described.   F. M. G. M.

Aromatic Arsenic Compounds. IV. Preparation of 3-Nitro 4-dimethylaminophenylarsinic Acid and of 3-Nitro-4-hydroxyphenylarsinic Acid. P. KARRER (*Ber.*, 1913, **46**, 515—517).—*p*-Dimethylaminophenylarsinic acid is readily nitrated on solution in a mixture of acetic and nitric acids. When the mononitrodimethylaminophenylarsinic acid, $NO_2 \cdot C_6H_3(NMe_2) \cdot AsO_3H_2$, is warmed with sodium hydroxide, it is converted into 3-nitro-4-hydroxyphenylarsinic acid (Benda and Bertheim, A., 1911, i, 63), which in turn, when reduced, gives rise to the base,

$$NH_2 \cdot C_6H_3(OH) \cdot As \vdots As \cdot C_6H_3(OH) \cdot NH_2,$$

corresponding with salvarsan.

When 3-nitro-4-dimethylaminophenylarsinic acid is similarly reduced, tetramethyltetra-aminoarsenobenzene,

$$NMe_2 \cdot C_6H_3(NH_2) \cdot As \vdots As \cdot C_6H_3(NH_2) \cdot NMe_2,$$

is obtained. This compound has no curative action towards mice infected with trypanosomes.

3-Nitro-4-dimethylaminophenylarsinic acid crystallises in lustrous, yellow needles.

The *hydrochloride* of *tetramethyltetra-aminoarsenobenzene* is a yellowish-white powder.   E. F. A.

Aromatic Arsenic Compounds. III. Triazoarylarsinic Acids and Some of their Derivatives. P. KARRER (*Ber.*, 1913, **46**, 249—255).—Some triazophenylarsinic acids have been prepared

by the addition of sodium azoimide to the corresponding diazotised amines. They are very stable towards dilute sulphuric acid, and cannot be hydrolysed to aminophenols, but the *o*-nitrated azoimides give up nitrogen when heated and undergo rearrangement to *o*-dinitroso-compounds (compare Zincke and Schwarz, A., 1899, i, 751), which can be readily condensed with dimethylaniline to phenazine derivatives.

p-*Triazophenylarsinic acid*, $N_3 \cdot C_6H_4 \cdot AsO_3H_2$, from *p*-aminophenylarsinic acid, crystallises in stout, white crystals, and gives a *monosodium* salt. 3-*Iodo-4-triazophenylarsinic acid* forms white crystals, and 3-*nitro-4-triazophenylarsenic oxide*, $N_3 \cdot C_6H_3(NO_2) \cdot AsO$, prepared from 3-nitro-4-aminophenylarsenic dichloride, which, in turn, is obtained from the arsinic acid, is a yellow, crystalline powder. 3-*Nitro-4-triazophenylarsinic acid*, a yellow, crystalline powder, loses nitrogen at 75°, and changes into 3 : 4-*dinitrosophenylarsinic acid*, $C_6H_3(NO)_2 \cdot AsO_3H_2$; this condenses with dimethylaniline to form 2-(or 3-)-*dimethylaminophenazine-7-arsinic acid*, $C_{14}H_{12}O_3N_3As$, as a blue dye which is very soluble in acetic acid and in sodium hydroxide. 2-*Nitro-3-triazophenylarsinic acid* also condenses with dimethylaniline, but 2-(or 3-)-*dimethylaminophenazine-8-arsinic acid* is insoluble in sodium hydroxide and has a reddish tinge. 3-Nitro-4-triazophenylarsinic acid can also be condensed with *o*-phenylenediamine in glacial acetic acid, when the *acetate* of 2 : 3 - *diaminophenazine* - 7 - *arsinic acid* separates as a brick-red powder. The free base (annexed formula) is yellow, gives a *diacetyl* derivative as a yellowish-brown powder, and when treated with sodium nitrite and acetic acid deposits the *compound*,

$$AsO_3H_2 \cdot C_6H_3 {\ll}^N_N{>} C_6H_2 {<}^{NH}_{-N} {>} N,$$
in the form of a brown powder.

J. C. W.

Iso- and Hetero-poly-salts. VIII. Alkylarsinomolybdates. ARTHUR ROSENHEIM and ROBERT BILECKI (*Ber.*, 1913, **46**, 539—557. Compare A., 1911, i, 109, 265; ii, 116, 612; this vol., ii, 59).—In order to examine further the extension of Werner's co-ordination theory to poly-acids by Miolati and Pizzighelli (A., 1908, ii, 595), the authors have prepared a series of alkylarsinomolybdates. They find that the number of MoO_4 or Mo_2O_7 radicles which unite with the alkylarsenates to form complex compounds is intimately connected with the number of oxygen atoms in the arsinate anion, and diminishes as the number of alkyl radicles present increases. The basicity of the hetero-poly-acids so formed is either equal to, or, generally, higher than, that of the corresponding alkylarsinates. Normal hetero-poly-salts could not in all cases be obtained. This is attributed to the fact that the acids contain weakly electro-negative complex ions which are hydrolysed on neutralisation of the solutions. The composition of the hetero-poly-salts is found to depend on the electro-affinity of the central atom ; more powerfully electronegative anions, such as the phenylarsinate- and *p*-hydroxyphenylarsinate-anions unite with MoO_4

radicles, whilst the weaker electronegative anions, such as the dialkylarsinate-anion, unite with Mo_2O_7 radicles.

The authors' experiments on solutions of cacodylic and molybdic acids agree with those of Miolati (*loc. cit.*). The latter, however, found breaks in the graph for the electrical conductivity of solutions of molybdic and methylarsinic acids at the proportions

$$AsMeO_3H : MoO_3 = 2 : 5 \text{ and } 1 : 10.$$
Since these figures did not agree with those obtained by the authors, the latter have plotted Miolati's graph on a larger scale, and find that it is not exact, somewhat weak breaks actually occurring at the proportions $AsMeO_3H : MoO_3 = 1 : 6$ and $1 : 9$. The corrected result agrees with the authors' determinations.

A boiling aqueous solution of sodium methylarsinate was saturated with molybdic acid, and, after concentration, an excess of guanidinium chloride was added. Two *guanidinium* salts were thereby obtained, the less soluble of which was composed of rectangular plates having the formula $(CN_3H_6)_2[AsMe(Mo_2O_7)_3],11H_2O$, whilst the more soluble salt consisted of white needles having the composition

$$(CN_3H_6)_8H_2\begin{bmatrix} \overset{Me}{As(Mo_2O_7)_4} & \overset{Me}{(Mo_2O_7)_4As} \\ -Mo_2O_7- \end{bmatrix},8H_2O.$$
In alkaline solution only the latter salt was obtained.

Sodium phenylarsinate, when similarly treated, also yielded two *guanidinium* salts. The less readily soluble salt, white leaflets,

$$(CN_3H_6)H[AsPh(MoO_4)_3],H_2O,$$
did not yield a neutral salt when boiled with excess of guanidinium carbonate. The more soluble salt, long, white needles,

$$(CN_3H_6)_5H_5\begin{bmatrix} AsPh(MoO_4)_4 & (MoO_4)_4AsPh \\ \underline{\qquad MoO_4-- \qquad} \end{bmatrix},6H_2O,$$
behaved according to conductivity measurements as the salt of a normal pentabasic substance. The hydrogen atoms could not be replaced by base in aqueous solution. In faintly alkaline solution, the more soluble salt was exclusively formed. When the latter salt was suspended in water and gently heated with guanidinium carbonate, the *salt*, $(CN_3H_6)_6H_2\begin{bmatrix} AsPh(MoO_4)_3 & (MoO_4)_3AsPh \\ OH & MoO_4 & OH \end{bmatrix},4H_2O$, was obtained. Precisely similar salts were obtained from those derivatives of phenylarsinic acid which did not form too powerfully electronegative anions; thus, from sodium *p*-aminophenylarsinate, the *guanidinium* salt, $(CN_3H_6)_2\begin{bmatrix} As\dfrac{C_6H_4 \cdot NH_2}{(MoO_4)_3} \end{bmatrix},5H_2O$, pale yellow leaflets, was prepared, whilst sodium *p*-hydroxyphenylarsinate yielded a *guanidinium* salt, $(CN_3H_6)_2\begin{bmatrix} As\dfrac{C_6H_4 \cdot OH}{(MoO_4)_3} \end{bmatrix},2H_2O$, white needles, and also a more soluble *salt*, crystallising in small plates. A complex salt derived from *p*-carboxyphenylarsinic acid could not be isolated.
Sodium cacodylate, when treated with molybdic acid and subsequently with guanidinum chloride, gave the *guanidinium* salt, $(CN_3H_6)_2\begin{bmatrix} AsMe_2(Mo_3O_7)_2 \\ (OH)_3 \end{bmatrix}$, colourless, anhydrous plates. The micro

crystalline *lead, copper,* and *silver* salts were also prepared. The *potassium* salt, prepared from potassium cacodylate in the usual manner, formed microscopic needles of the formula $K_2H\begin{bmatrix} AsMe_2(Mo_2O_7)_2 \\ (OH)_2 \end{bmatrix}$. The corresponding *barium* salt was obtained by the action of barium chloride on the sodium salt.

In a similar manner, the *guanidinium* salt,

$$(CN_3H_6)_2H\begin{bmatrix} AsPh_2(Mo_2O_7)_2 \\ (OH)_2 \end{bmatrix},H_2O,$$
white, hexagonal plates, was obtained from sodium diphenylarsinate.

An aqueous solution of trimethylarsonium hydroxide was saturated with molybdic acid at its boiling point. The solution, when concentrated, deposited a yellow, microcrystalline substance,

$$AsMe_3(OH)_2H_3\begin{bmatrix} AsMe_3(Mo_2O_7)_2 \underset{-O-}{} (Mo_2O_7)_2AsMe_3 \end{bmatrix},3H_2O.$$
When, however, guanidinium chloride was added to the above solution before the latter compound had separated, the *guanidinium* salt,

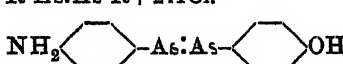
$$(CN_3H_6)_3H_3\begin{bmatrix} AsMe_3(Mo_2O_7)_2 \underset{-O-}{} (Mo_2O_7)_2AsMe_3 \end{bmatrix},$$
was obtained as microscopic, white plates.

When triphenylarsine oxide was dissolved in boiling aqueous sodium molybdate solution and the latter acidified by gradual addition of hydrochloric acid, a yellow, amorphous *substance,* $\begin{bmatrix} As\dfrac{Ph_3}{Mo_2O_7} \end{bmatrix}$, was obtained.

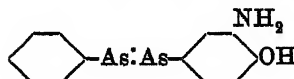
H. W

Preparation of Organic Arsenic Compounds. HEINRICH BART (D.R.-P. 254345. Compare this vol., i, 115).—When solutions of *iso*-diazo-compounds react with diarylarsenious oxides (or acids) they give rise to triarylarsine hydroxides or oxides :

$$RN{:}NOH + R_2As{\cdot}OH = N_2 + R_3AsO + H_2O.$$
A 10% solution of sodium *p*-nitro*iso*diazobenzene is slowly treated with dinitrodiphenylarsenious acid and sodium hydroxide (1 mol.) ; on slowly heating to 75—80°, nitrogen is evolved, and on the addition of acid the trinitrotriphenylarsine oxide separates as a brown precipitate.

The required *dinitrodiphenylarsenious acid* is obtained by the careful reduction of dinitrodiphenylarsinic acid with hydrogen iodide in acetic acid solution ; when heated it decomposes energetically without fusion.


F. M. G. M.

Preparation of Unsymmetrical Arseno-compounds. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 253226).— Unsymmetrical aromatic arseno-compounds have previously been prepared (this vol., i, 116), and this reaction has now been extended to the case of compounds containing both aliphatic and aromatic residues.


3-*Amino*-4-*hydroxybenzenearsenomethane* (annexed formula), a yellow powder soluble in dilute acids and alkaline hydroxides, is obtained when a methyl-alcoholic solution of 3-amino-4-hydroxyphenylarsenious oxide is treated with a similar solution of methyl arsenious oxide (A., 1906, i, 488), water added, and the mixture reduced with sodium hyposulphite.

$$CH_3{\cdot}As{:}As\!\!\left\langle\!\!\!\begin{array}{c} NH_2 \\ \\ OH \end{array}\!\!\!\right.$$
One or both of the arsenious oxides in the foregoing reaction can be replaced by the corresponding acids, in which case the reduction is carried out with stannous chloride and hydrogen iodide at $-10°$ to $-20°$.   F. M. G. M.

Preparation of Aromatic Arseno-compounds. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 254187. Compare A., 1909, i, 347; 1910, i, 148).—When aromatic arsinic acids are reduced in strongly acid solution they give rise to primary arsines of general formula $R \cdot AsH_2$ ($R = $ aryl), which can be condensed with aryl-arsenious oxides or haloids to yield aromatic arseno derivatives (this vol., i, 117): $R \cdot AsH_2 + R \cdot AsO = R \cdot As : As \cdot R + H_2O$; $R \cdot AsH_2 + R \cdot AsCl_2 = R \cdot As : As \cdot R + 2HCl$.

$NH_2 \langle \quad \rangle - As:As - \langle \quad \rangle OH$ *4 - Amino - 4′ - hydroxyarsenobenzene* (annexed formula), a yellow powder, decomposes at about $200°$; 3-amino-4-hydroxy-4′-glycylarsenobenzene (this vol., i, 116) darkens at $120°$ and decomposes violently at $150°$, and *3-amino-4-hydroxyarsenobenzene*

$\langle \quad \rangle - As:As - \langle \quad \rangle OH$ (annexed formula) forms a yellow powder.
                                      Other compounds mentioned as being prepared by this method are 4 : 4′-diamino-arsenobenzene and 3 : 3′-diamino-4 : 4′-dihydroxyarsenobenzene.   F. M. G. M.

Preparation of Aromatic Stibinic Acids. CHEMISCHE FABRIK VON FRIEDR. HEYDEN (D.R.-P. 254421. Compare Trans., 1911, 99, 2286).—Phenylstibinic acid has previously been prepared (Hasenbäumer and others) by a somewhat complicated series of reactions; the following simple method is now described.

Antimony trioxide (140 parts) is dissolved at the ordinary temperature in 764 parts of hydrochloric acid (D 1·123), treated with sodium hydroxide (600 parts) in water (3000 parts), and rapidly cooled to $0°$, when part of the sodium antimonite separates. A solution of anilino-diazonium sulphate (prepared from 93 parts of aniline and 147 parts of sulphuric acid) is then rapidly stirred in, either with or without the addition of copper paste; after some hours the mixture is carefully neutralised with sulphuric acid, filtered, and the phenylstibinic acid precipitated by the addition of hydrochloric acid. To purify the product from antimony trioxide it is dissolved in hot hydrochloric acid (D 1·123), and the solution saturated with solid ammonium chloride, when on cooling *phenylstibinic oxychloride* separates in glistening leaflets; this is isolated, decomposed with sodium carbonate, and the pure phenylstibinic acid precipitated with hydrochloric acid. As thus prepared, phenylstibinic acid is stable at $250°$ (Hasenbäumer gives decomp. point $200°$).

p-*Hydroxyphenylstibinic acid* and p-*acetylaminophenylstibinic acid* are similarly prepared from p-aminophenol and monoacetyl-p-phenylene diamine respectively; the *sodium* salt of the latter dissolves in water with a neutral reaction. p-*Aminophenylstibinic acid*, obtained by the hydrolysis of the foregoing acid, combines readily with aldehydes

(salicylaldehyde) to furnish hydroxybenzylidene derivatives or on diazotisation gives rise to a red azo-derivative with alkaline β-naphthol.

F. M. G. M.

Preparation of Nuclear Substituted Mercury Derivatives of Aromatic Hydroxy-acids CHEMISCHE FABRIK VON FRIEDR. HEYDEN (D.R.-P. 255030).—The following therapeutically active organic derivatives of mercury have now been prepared.

Mercurydisalicylic acid, $Hg[C_6H_3(OH)\cdot CO_2H]_2$, a colourless powder, insoluble in water, is obtained by the reduction of *o*-hydroxymercurisalicylic anhydride with sodium formaldehydesulphenate, and is employed in the form of its neutral *alkali* salts.

Mercury-bis-sulphosalicylic acid, also employed in the form of its *sodium* salt, is similarly prepared from sodium mercurisulphosalicylate.

Mercury-bis-arsenosalicylic acid, a colourless powder, is obtained from mercury arsenosalicylic acid.

*Sodium mercuri-bis-*2-*naphthol-*3 : 6 *disulphonic acid* and *mercury-bis-*4-*hydroxy-*m-*tolyl-*1-*arsinic acid* are also employed in the form of their crystalline *sodium* salts. F. M. G. M.

Physiological Chemistry.

The Influence of Phosphorus on Respiratory Metabolism. OTTO HIRZ (*Zeitsch. Biol.,* 1913, **60**, 187—310).—The respiratory exchange in rabbits sinks regularly during inanition. On the second day the nitrogenous output and the urea rise and remain at a constant level as the organ protein is utilised. In fat animals the consumption of the organ protein is delayed. In phosphorus poisoning the decrease in respiratory metabolism is not a specific effect of the poison on metabolism, but is secondary to pain and other symptoms produced. With small doses there is a slight increase in respiratory activity. The nephritis produced lessens the output of nitrogen, but in fat animals this is preceded by an increase. Carbohydrate metabolism is unaffected. The combustion of fat increases. No support is found for the hypothesis that the fat which appears in the organs ("fatty degeneration") is of protein origin. The permeability of the blood vessels is greatly increased.

W. D. H.

The Coagulation of Blood. WILHELM CRAMER and HAROLD PRINGLE (*Quart. J. expt. Physiol.,* 1913, **6**, 1—12).— If oxalate plasma is filtered through a Berkefeld filter, it does not clot when calcium chloride is added to it. This is due to removal of the platelets, which are still present in oxalate plasma prepared in other ways. The addition of calcium chloride to ordinary oxalate plasma liberates thrombokinase (Howell's thromboplastin) from the

platelets. Soluble calcium salts, in addition to this primary effect on the platelets, contribute also to the formation of fibrin under the influence of the substance liberated from the •platelets. In paraffined tubes blood remains fluid because the platelets are intact; when transferred to glass tubes the platelets in contact with the glass disintegrate, and clotting ensues. The phenomena described by Nolf as "thromboplastic agencies" and "centres of coagulation" are due to the presence of platelets. Plasma free from platelets are not susceptible to the action of "thromboplastic agencies."

W. D. H.

The Plasma of Propeptone. HENRI STASSANO (*Compt. rend.*, 1913, **156**, 735—738).—The plasma obtained after the intravenous injection of propeptone differs in several respects from plasma, to which salts have been added. The first is coagulated when diluted either with distilled water or even with a solution of an anti-coagulating salt, whilst the latter is only coagulated on dilution with water. The plasma of propeptone behaves thus as a mixture of serum and fibrinogen in decalcified solution. The coagulation of propeptone plasma on dilution is unaffected by change in temperature, whilst that of the saline plasma is checked by cooling. In tubes coated with paraffin wax, the former plasma coagulates on dilution with only a slight retardation, whilst the latter remains indefinitely liquid. The coagulating power of propeptone plasma towards the peritoneal serum from a horse is greater at the moment of dilution than two hours afterwards, whilst that of saline plasma steadily increases after dilution. These differences point to the fact that, whilst in the saline plasma the fibrin-ferment is in an inactive state, in the plasma of propeptone it is in the active state. W. G.

The Transference of the Digestion Products of Proteins from the Mother to the Fœtus. GIUSEPPE BUGLIA (*Biochem. Zeitsch.*, 1913, **48**, 362—372).—The distribution of nitrogen in the blood of the fœtus and mother in the case of dogs was determined both when digestion products had been injected into the jugular or femoral vein, and when either no injection had been made, or only saline had been administered. From the comparison of the various results obtained, the conclusion is drawn that protein digestion products can pass directly from the mother to the fœtus.

S. B. S.

The Influence of Nutrition on the Amylase Content of Human Saliva. O. LOVATT EVANS (*Biochem. Zeitsch.*, 1913, **48**, 432—447).—The amylase content (estimated by determining the amount of maltose produced from a given starch solution in a given time by Bertrand's method) increases after a meal. The increase commences twenty to thirty minutes after a meal, and lasts for two to three hours, when it reaches a maximum and then wanes. The activity remains then small until the next meal is taken. The content is not affected after mock feeding (mastication of food without swallowing). A meal of purely protein content does not

increase the amylase. The mechanism of the secretion can be explained by assuming that carbohydrates act on the mucous membrane of the stomach and produce a hormone. The increase in amylase content is to be ascribed principally to the saliva produced by the parotid gland, which has about four times the enzymatic activity of that of the remainder of the glands. The parotid, furthermore, produces about half the total volume of the saliva.

S. B. S.

The Behaviour of Plasteins in the Animal Body. I. The Relationships of Plasteins to Peptone Poisoning. ERICH VON KNAFFL-LENZ and ERNST P. PICK (*Arch. expt. Path. Pharm.*, 1913, **71**, 296).—If pepsin hydrochloric acid acts on a poisonous peptic digest, substances of higher molecular weight (plasteins) are formed which are not poisonous. The formation of plasteins in the body is regarded as protective. If the plasteins are again subjected to gastric action, poisonous products again arise; tryptic digestion is ineffective in this direction. The phenomenon is thus a reversible one. The final cleavage products of protein digestion are not poisonous. W. D. H.

Pancreatic Digestion. FRIEDRICH AUERBACH and HANS PICK (*Biochem. Zeitsch.*, 1913, **48**, 425—426).—Attention is called to the fact that, whereas natural pancreatic juice possesses the optimal hydroxyl ion concentration for lipoclastic or peptoclastic function, the digestion of proteins proceeds best in a medium more distinctly alkaline. This indicates that the preliminary digestion of proteins takes place for the most part in the stomach rather than in the intestine, the function of which is to digest the peptones. S. B. S.

Comparative Physiology of Digestion. VI. Cellulose and Cellulose-dissolving Enzymes in the Hepatopancreas of the Snail (Helix pomatia). JERZY STANISŁAW ALEXANDROWICZ (*Pflüger's Archiv*, 1913, **150**, 57—86).—Attention is directed to the two forms of crystalline cellulose, namely, those in plant sections, and the sphæro-crystals prepared *in vitro* by Gilson and Bütschli. The former have strong, doubly refracting properties; the sphæro-crystals are only feebly anisotropic. In plant membranes hemicelluloses are present, which increase their anisotropy. Crystallised cellulose is dissolved by the snail's hepatopancreas. Hence celluloses of different origin differ a good deal in solubility in the juice. It is suggested that the enzymes which dissolve cellulose and hemicellulose may be investigated microscopically in the study of the chemical composition of vegetable membranes. W. D. H.

The Synthetic Powers of the Organism of the Dog. EMIL ABDERHALDEN (*Zeitsch. physiol. Chem.*, 1913, **83**, 444—457) — The dog under observation was kept for three months on carbohydrate, fat, and the completely cleaved products of meat hydrolysis. It gained 10 kilograms in weight, and renewed its fur. Tryptophan and tyrosine are essential, and their absence is followed by untoward symptoms. Hopkins' view that tryptophan is essential for the formation of certain internal secretions is regarded as probable but unproven. W. D. H.

Action of Ammonium Salts, Glucosamine and Gelatin on the Nitrogen Balance. EMIL ABDERHALDEN and ARNO ED. LAMPÉ (*Zeitsch. physiol. Chem*, 1913, **83**, 409—424).—Experiments similar to those previously carried out on dogs are now recorded on two pigs. On most days there was a loss of nitrogen; in this and some other details the results differ from those of Grafe on pigs. A further series of experiments on a dog yielded much the same results. This dog died of tetanus, which is attributed to tetanus spores in the gelatin given. This is the first recorded instance of tetanus infection through the alimentary tract.

<div align="right">W. D. H.</div>

Utilisation of Calcium and Phosphoric Acid Compounds by the Animal Organism. GUSTAV FINGERLING (*Landw. Versuchsstat*, 1913, **79**—80, 847—870. Compare *ibid.*, **75**, 1).—Feeding experiments in which goats received, in addition to straw, blood nuclein, starch, and oil, the following substances as sources of phosphorus: phytin, lecithin, casein, nuclein, nucleic acid, and disodium phosphate. The food was mixed with molasses to make it palatable.

The results showed that there is no essential difference in the utilisation of the different forms of phosphorus. The imperfect assimilation of the phosphoric acid of crude foods must, therefore, be due to other causes.

<div align="right">N. H. J. M.</div>

Comparative Investigations on the Content of Aminoacids in the Different Constituent Parts of the Nervous System. II. The Amino-acids of the Grey and White Substance of the Brain. EMIL ABDERHALDEN and ARTHUR WEIL (*Zeitsch. physiol. Chem.*, 1913, **83**, 425—440).—The results of the analyses of grey and white brain matter are given in tables, together with the methods used. The details relate to water, total nitrogen, ash, and various amino-acids.

<div align="right">W. D. H.</div>

The Action of the Diastatic Enzyme on the Glycogen within the Cells JULIUS GRODE and ERNST J. LESSER (*Zeitsch. Biol.*, 1913, **60**, 371—387).—The surviving liver and muscles of winter (glycogen-rich) frogs in oxygenated Ringer's solution lose little or none of their glycogen. The same was stated by Schiff in 1859. If the cells are destroyed mechanically, the glycogen disappears rapidly. The enzyme responsible for the change is considered to exist in the cells as a zymogen, which is converted into the active enzyme as the cells are killed.

<div align="right">W. D. H.</div>

The Behaviour of the Glycogen of the Frog in Anoxybiosis and Restitution. III ERNST J. LESSER (*Zeitsch. Biol.*, 1913, **60**, 388—398).—In the living summer frog (poor in glycogen) the anoxybiotic glycogen disappearance is about 50% in two hours at 20°. In restitution in the summer, contrary to what is seen in winter frogs, there is a well-marked new formation of glycogen. Under anoxybiotic conditions lasting two or three days, the

glycogen also is lowered by about 50%. Normal frog's blood contains no sugar when tested for by the method of Michaelis and Rona. In anoxybiosis the blood contains 0 07% sugar, and minute amounts may pass into the urine.   W. D. H.

Comparative Anatomy and Physiology of the Pituitary Body. Percy T. Herring (*Quart. J. expt. Physiol*, 1913, **6**, 73—108) —The pituitary bodies of the classes of vertebrates resemble one another in essential features. In elasmobranch fishes, however, the nervous lobe is absent.

No portion of the epithelial lobe in any case contained the active principles associated with the posterior lobe in mammalia. The *pars intermedia* by itself or the colloid matter separated from it have no specific effect on blood-pressure or kidney. The hormone which affects the mammary gland is obtainable from the skate's pituitary (which has no nervous lobe), and therefore appears to be a separate substance. It is still more abundant in the posterior (nervous) lobe in other animals; it is probable that it is a product of the epithelial lobe, and is stored in the *pars nervosa*. The latter is composed of modified ependyma and neuroglia cells permeated by a gelatinous substance containing fine granules and hyaline bodies. The granules are considered to be the representatives of the active principles of the nervous lobe; they are the products of the cells of the *pars intermedia* (in origin, a portion of the epithelial lobe); these are carried to, elaborated in, and stored by the *pars nervosa*.   W. D. H.

The Effects of the Administration of Extracts of the Pituitary Body and Corpus Luteum to Milch Cows. W. Gavin (*Quart J. expt. Physiol.*, 1913, **6**, 13—16).—Under conditions of farm practice, no commercial benefit arises from the administration to dairy cows of these glandular extracts, whether given by the mouth, under the skin, or intravenously. Intravenous injection of pituitary extract causes more milk to collect in the lower parts of the udder, but no alteration in the total quantity per diem, or in the quality of the milk, occurs.   W. D. H.

The Effect of Pituitary and Corpus Luteum Extracts on the Human Mammary Glands Edward A. Schäfer (*Quart. J. expt. Physiol.*, 1913, **6**, 17—20).—Observations on a woman of twenty eight nursing her second child show that injection of pituitary extract intramuscularly, produced a tingling sensation in the breasts, and an increased flow of milk. The effect was not lasting, and a long time elapsed before there was again enough milk to feed the child. The effect of similar injections of extract of the corpus luteum was doubtful.   W. D. H.

The Liberation of Ions and the Oxygen Tension of Tissues during Activity. Herbert E. Roaf (*Proc. Roy. Soc.*, 1913, *B*, **86**, 215—218).—A preliminary account of an investigation of muscle by various kinds of electrodes, and the results give evidence that

hydrogen and probably chlorine ions are liberated during the act of contraction. There is also a fall in oxygen tension.   W. D. H.

The Summation of Muscular Contractions. GEORGE R. MINES (*J. Physiol.*, 1913, **46**, 1—27).—Reasons are given for thinking that the liberation of acid in muscle as the result of excitation precedes the act of shortening and possibly causes it. When a second excitation can be produced before the first localised concentration of acid has had time to diffuse away, the result may be a summation of these localised concentrations, and so a greater effect on the contractile mechanism. Such an effect may, however, occur at a time when the general hydrogen ion concentration of the muscle is such that further increase tends only to diminish the power of the response of the muscle.   W. D. H.

The Energy Degraded in the Recovery Processes of Stimulated Muscles. ARCHIBALD V. HILL (*J. Physiol.*, 1913, **46**, 28—80). —A thermoelectric apparatus is described by which it is possible to estimate and record rapidly the rise of temperature of a muscle to within a millionth of a degree. The production of heat in a muscle excited in oxygen either by a single shock or a short tetanus continues for long periods after the mechanical response is over; but after the muscle has been kept in nitrogen for an hour there is no trace of heat production following the contraction; on being restored to oxygen this returns. Previous excitations or a prolonged tetanus, which diminish the oxygen tension in the muscle, lessen the heat production after the contraction. The "delayed heat" is due to usage of oxygen in the process of recovery; and recovery does not occur in the absence of oxygen. It is suggested that the contraction is due to liberation of lactic acid from some precursor; the acid increases the tension in some colloidal structure of the tissue; this precursor is rebuilt after contraction, oxygen is used, and heat is produced; when oxygen is absent, the heat produced is due to the breakdown of the lactic acid precursor. The oxygen appears to be used largely in oxidations whereby the molecular machine (like a steam engine charging an accumulator) builds up substances containing considerable amounts of free energy, which, as in the accumulator, can be discharged on subjecting the muscle to stimuli.   W. D. H.

The Extractives of Muscle. III. TEMISTOCLE JONA (*Zeitsch. physiol. Chem.*, 1913, **83**, 458—467).—Muscle extracts contain a fairly large percentage of gelatin, or rather of substances which behave like gelatin towards Schmidt's reagent. A dipeptide was also separated which, on analysis and determination of its constants, appears to be identical with the anhydride of *d*-alanyl-*d*-alanine, which E. Fischer prepared by treating the ethyl ester of this dipeptide with ammoniacal alcohol.   W. D. H.

Products of Protein Cleavage which Produce Fatigue, and their Influence. WOLFGANG WEICHARDT and ERWIN SCHWENK (*Zeitsch. physiol. Chem.*, 1913, **83**, 381—402).—From the muscle-

proteins, by means of electrolysis, certain high molecular products were obtained which cause, when injected into animals (mice), certain toxic symptoms, such as the signs of fatigue, slowing of the respiration, and depression of the body temperature. The effect of these *keno-toxins*, as they are termed, can be counteracted by a number of substances of which the chemical composition is known, for instance, succinimide, glutarimide, phthalimide, piperidine, creatine, guanidine hydrochloride, and others. The same effect is produced by a group of substances of unknown composition which are spoken of as *retardins*; these can be extracted by acetone from digested protein. Further work on the relationships between activity and chemical composition is promised. W. D. H.

Physiological Permeability of Cells. V. Narcosis of Lipoid-rich and Lipoid-poor Tissues of the Same Kind. LOUIS CHOQUARD (*Zeitsch. Biol.*, 1913, 60, 101—162).—Heart muscle is richer in lipoids than skeletal muscle; the effect of narcotics on each was tried in order to determine the influence of lipoids. According to the Meyer-Overton doctrine, narcotics of the aliphatic series should produce narcosis in less concentration when applied to cardiac muscle as compared to skeletal muscle. But to this a number of noteworthy exceptions were found; ether, acetone, and acetylacetone produce narcosis in smaller concentrations in the lipoid-poor skeletal than in the lipoid-rich heart muscle. Acetal narcotises heart muscle, however, in much smaller concentrations than are necessary for skeletal muscle (which is in consonance with the lipoid hypothesis), but acetal narcotises skeletal muscle in higher concentrations than ether. The introduction of a halogen atom into the molecule leads to the result that the heart muscle is narcotised by a smaller concentration than skeletal muscle. The partition coefficient, solubility in fat/solubility in water, does not account for this, for chloral hydrate, with the low coefficient of 0·22, narcotises heart muscle in the same concentration as ethyl bromide, which has a very high coefficient; probably the chemical influence of the halogenised material on the somewhat different biochemical structure of the two kinds of muscle is here being dealt with.

In the group of the univalent alcohols, the molecular weight increases as the lipoid solubility and the narcotic power in both tissues, but this relationship is not strictly parallel. For instance, the elevation of the partition coefficient of ethyl alcohol, as compared with propyl alcohol, is much greater than the rise in narcotic effect; the difference found was greater than stated by Overton.

Similar exceptional instances are found among the aldehydes. These experiments lead to the conclusion that the Meyer-Overton hypothesis is untenable. W. D. H.

The Presence of Boron in the Animal Series. GABRIEL BERTRAND and HENRI AGULHON (*Compt. rend.*, 1913, 156, 732—735). —The authors have extended their work (compare A., 1912, ii, 854) on the presence of boron in animals, and have examined twenty-

seven other species from the different classes, finding boron in practically every case. They therefore consider that boron exists normally in very small proportions in the organism of all animals, being most abundant in the species of marine origin, whilst in others it is present only to the extent of 1 part in 100,000,000 of the living matter.   W. G.

The Composition of the Tissues with Respect to Non-volatile Fatty Acids and Cholesterol, and the Possible Existence of a "Lipocytic Constant." ANDRÉ MAYER and GEORGES SCHAEFFER (*Compt. rend.*, 1913, **156**, 487—491). — The authors have determined the amount of non-volatile fatty acids and cholesterol in the various organs of a number of normal animals, and find that, whilst the variation in content of the same organ for different animals of the same species is moderately wide, more particularly in the case of the fatty acids, yet certain points stand out clearly, namely, whilst these variations occur for a given organ of animals of the same species, the values group themselves in moderate limits round a mean value, but from one species to another very different values are obtained for the content with respect to these substances for the same organ, the values being greater for birds than mammals, and still greater for eels. The so-called "lipocytic constant," $\frac{\text{cholesterol}}{\text{fatty acids}}$, is characteristic for each organ, and independent of the species.   W. G.

The Action of Ultra-violet Rays on the Ear of the Rabbit. VENCFSLAS MOYCHO (*Compt. rend.*, 1913, **156**, 577—579) —Exposure of the external surface of the ear to short irradiation (thirty seconds) produces no visible effect. If this is prolonged for one to twelve minutes, however, a series of phenomena appears. After two to five hours, local vaso-dilatation is noticeable, the portion which was exposed to the rays becoming red, this being accompanied by rise in temperature and tumefaction. The maximum effect is reached in twenty-four hours, then diminishes, and finally at the end of seven to twelve days the redness and high temperature completely disappear, and a persistent brown pigment appears. The irradiation appears to have a stimulating effect on the hair growth. The most active rays are those having $\lambda = 3100$—2900, and the cells acted on are situated at a depth of 1/10th to 1/6th mm. below the surface.   W. G.

The Influence of Heat on the Physico-chemical Behaviour of Human Milk, Cow's Milk, and Butter-Milk. PAUL GROSSER (*Biochem. Zeitsch.*, 1913, **48**, 427—432).—The milk was submitted to ultra-filtration in Bechhold's apparatus before and after boiling, and the amounts of calcium, nitrogen, and phosphorus in the filtrates were compared. It was found that after heating, the phosphorus and nitrogen in the filtrate of cow's milk was scarcely affected, whereas that of human milk was appreciably diminished.

In both kinds of milk the calcium in the filtrate diminished after heating. S. B. S.

The Therapeutic Action of Yeast on the Alimentary Multiple Polyneuritis of Guinea-pigs and Pigeons. MAX BARSICKOW (*Biochem. Zeitsch.*, 1913, **48**, 418—424).—The addition of various yeast preparations to the insufficient diet which produces the beri-beri-like symptoms in animals was investigated. In the case of guinea-pigs fed on oats and water, or on this diet with rice alone, the addition of yeast preparations exerted no beneficial effect. In the case of pigeons, however, fed on a similar diet, the beneficial effect of certain yeast preparations was marked. This effect was produced both by yeast of which the enzymes were destroyed by heat, by living yeast, and by permanent yeast preparations, but not by "cerolin," a preparation containing only the constituents of yeast soluble in organic solvents. It is suggested that the therapeutic action is due to nucleins or salts. S. B. S.

The Behaviour of Blood Sugar in Normal and Pathological Cases. VI. Blood-sugar Content in Cases of Anæmia, Liver, Intestinal and Other Diseases. FR. ROLLY and FR. OPPERMANN (*Biochem. Zeitsch.*, 1913, **48**, 471—479. Compare this vol., i, 307).—Severe anæmia, with its accompanying diseases, causes generally an increase in blood sugar, which is more or less normal in quantity in mild cases. In Greves's disease there is an increase only in severe cases. In Addison's disease the amount is either normal or subnormal; in the latter case only when the disease is severe, and unaccompanied by infectious or toxic factors (tuberculosis, etc.). In scorbutic and eclamptic cases high values are generally found, which are due partly to the toxins. An increase was also found in cases of myasthenia and gangrene. In diseases of the liver and the alimentary tract there is an increase only when toxic factors are present (carcinoma, dyspnœa, abscesses, fever, etc.). S. B. S.

The Manganese Content of Transplanted Tumours. FLORENTIN MEDIGRECEANU (*Proc. Roy. Soc.*, 1913, *B*, **86**, 174—179).—The amount of manganese in transplanted mouse and rat tumours is small (0·004 to 0·012 mg. per 100 grams of fresh material), which is about the same as in the normal mammary gland of the mouse. No differences in the manganese of sarcoma and carcinoma were discoverable. W. D. H.

The Influence of Vapours of Technical Importance on the Organism. XXXII and XXXIII. Amyl Acetate and *cyclo*-Hexanyl Acetate. KARL B. LEHMANN (*Arch. Hygiene*, 1913, **78**, 260—273).—Both the substances investigated have a relatively small toxicity, the *cyclo*hexanyl acetate being about three times as toxic as amyl acetate, as measured by the amount necessary to produce narcosis. This greater toxic effect is, however, counterbalanced by the fact that it is considerably less volatile. Both substances can be safely employed in technical operations when the necessary precautions for ventilation, etc., are taken. S. B. S.

The Influence of Certain Cardiac Medicaments on the Electrocardiam Curve. ADOLF BICKEL and MICHAEL PAVLOV (*Biochem. Zeitsch.*, 1913, **48**, 459—470).—Certain digitalis and strophanthus preparations, and especially digistrophan, have the tendency to heighten certain points in the curve, whereas, in larger doses, the height of these points is diminished. In all cases there is a lengthening both of the heart phase and pause. Cardiotonin also causes a slowing of the heart action, increasing both the heart phase and pause. Valerian has no influence in this respect. The author discusses the therapeutic application of these various drugs, as deduced from their effects on the electrocardiam curve. The experiments were carried out with dogs and rabbits.   S. B. S.

The Relationship between Heart Drugs and the Physiological Action of Cations. ARTUR VON KONSCHEGG (*Arch. expt. Path. Pharm.*, 1913, **71**, 251—260).—If a frog's heart is perfused with Ringer's solution free from calcium, the stoppage so produced can be counteracted by strophanthine; but if the solution is free from both potassium and calcium, strophanthine has not the power to resuscitate the heart. A heart poisoned with potassium again beats when strophanthine is applied. If a heart is stopped by a calcium-free solution, adrenaline and camphor cause weak contractions of the sinus, but caffeine has no effect.   W. D. H.

The Depressor Effect of Adrenaline on Arterial Pressure. WALTER B. CANNON and HENRY LYMAN (*Amer. J. Physiol.*, 1913, **31**, 376—398).—Stimulation of the cat's adrenal causes vaso-dilation and a fall of arterial pressure. Small doses of adrenaline have the same effect. After pithing, or extreme depression, the effect is pressor, but ergotoxine restores the depressor action. The effects are attributed to opposite actions of adrenaline according to the state of the muscle; relaxation occurs when the muscle is tonically shortened, and contraction when relaxed.   W. D. H.

Adrenaline and Glycamia. HENRI BIERRY and (Mlle.) LUCIE FANDARD (*Compt. rend.*, 1913, **156**, 480—482).—After injection of adrenaline to the extent of 0·001 gram per kilo. of body-weight, either intravenously or into the peritoneal cavity, there is marked progressive hyperglycamia and also a considerable rise in the combined sugar of the blood, which, however, increases more slowly than the free sugar.   W. G.

[Physiological] Action of Scopolamine. MAX CLOETTA (*Arch. expt. Path. Pharm.*, 1913, **71**, 290—292).—Polemical remarks on the controversy between Hug and Cushny (compare A., 1912, ii, 790; this vol., i, 226).   W. D. H.

The Action of Veratrine and Protoveratrine. RUDOLF BOEHM (*Arch. expt. Path. Pharm.*, 1913, **71**, 269—289).—The intensity of the action of protoveratrine on the frog's heart is much greater than that of veratrine; on nerve it is less active; on skeletal muscle

it is also less active, although its effects are substantially the same
in kind.   W. D. H.

The Behaviour in the Organism of 2-Phenylquinoline-4-
carboxylic Acid (Atophan). W. Skórczewski and J. Sohn
(*Bull. Acad. Sci. Cracow*, 1912, **9,** *A,* 885—887).—After administration
of atophan, the urine gives the following reactions: (1) A yellow
colour with concentrated hydrochloric acid. (2) A yellow precipitate
with phosphotungstic acid. (3) A dark green colour with ammonium
sulphate and ammonia. (4) A characteristic diazo-reaction with
Ehrlich's reagent. These reactions are given neither by the drug itself
nor by normal urine, but are due to an acid, which can be extracted
from the concentrated urine by ether, and which after recrys-
tallisation by ether and light petroleum has m. p. 231—232° after
turning brown at 200°. Its formula, $C_{18}H_{11}O_3N$, corresponds with
that of hydroxyphenylquinolinecarboxylic acid. The position of the
hydroxyl group in this compound is not yet determined. S. B. S.

Action of Arseno-aromatic Compounds ("606" and Neo-
salvarsan) on the Hæmoglobin of the Blood. R. Dalimier
(*Compt. rend.*, 1913, **156,** 629—631).—Salvarsan (diaminodihydroxy-
arsenobenzene) has no action on hæmoglobin either *in vitro* or *in
vivo*. Neo-salvarsan (sodium diaminodihydroxyarsenobenzene-
methylenesulphenate), on the other hand, produces marked hæmo-
lysis and reduction of the oxyhæmoglobin when acting *in vitro*. On
injection into the ear-vein of the rabbit, only a fugitive hæmolysis
is noticeable, there being no reduction of the oxyhæmoglobin.
                                                            W. G.

Chemistry of Vegetable Physiology and Agriculture.

Protein and Phosphorus Content of Azotobacter Cells.
Conrad Hoffmann (*Centr. Bakt. Par.*, 1913, ii, **36,** 474—476). Com-
pare Abstr., 1910, ii, 988).—During the course of earlier investigations
the author found the protein content of *Azotobacter* cells to vary from
8·3—12·0%, and the phosphorus content to be 2·51—2·97%. These
amounts vary considerably from those found by Stoklasa (A., 1911,
ii, 429), and it is suggested that the differences are possibly due to
differences in the methods employed in preparing the samples for
analysis. The relatively high content (61·25—71·87%) found by
Stoklasa might be attributed to removal of carbohydrates during
washing, whereas the material used by the author was obtained,
without washing, from agar cultures. If this were the case, the
protein: phosphorus ratio ought to be the same in the two sets of
results, but such agreement does not appear to exist.   H. B. H.

The Chemical Composition of Tubercle bacilli. TADEUSZ KOŹNIEWSKI (*Bull. Accad. Sci. Cracow*, 1913, **10**, *A*, 942—947).— When the bacteria are extracted with cold 96% alcohol, a small quantity of extract is obtained, which contains lipoids, colouring matter, and other substances. If the bacteria are extracted after alcohol treatment with hot acetone, relatively large quantities (20—24% of the dried bacteria) of a white, waxy substance are obtained, which is only slightly soluble on heating in most organic solvents, and is insoluble in mineral acids. On prolonged boiling with alcoholic potassium hydroxide, it yields a soap. Its formula agrees approximately with that of substance $C_{12}H_{24}O$, and the saponification number found was 125·2. The substance is probably an ester. When the bacteria are treated with 3—5% hydrochloric acid, a reducing sugar appears to pass into solution, which, even in concentrations of 2%, is optically inactive. The solution of sugar ferments with yeast. The author failed, in other experiments, to isolate glucosamine, from which he draws the conclusion that the bacteria do not contain chitin. S. B. S.

Proteus vulgaris Considered as a Producer of Indole. ALBERT BERTHELOT (*Compt. rend.*, 1913, **156**, 641—643. Compare Herter and Broeck, A., 1911, ii, 758).—Numerous observers having obtained varying results as to the production of indole by different specimens of *Proteus vulgaris*, Hauser, the author has made a careful study of the question, and finds that, in the case of the fifty-seven specimens examined, all the *Proteus vulgaris* are capable of attacking tryptophan, giving either indole or indoleacetic acid, or more generally, a mixture of these two substances, and that there is no reason for distinguishing a species *Bacillus proteus anindol·y·n·s*, as distinct from the *Proteus*-giving indole. The action of the microbe is variable not only with different specimens, but for the same race at different ages and under different conditions. W. G.

Influence of Cæsium, Rubidium, and Lithium Salts on Yeast as Compared with Potassium and Ammonium. THOMAS BOKORNY (*Bied. Zentr.*, 1913, **42**, 141—142; from *Allgem. Brauer-Hopfenzeit.*, 1912, **52**, 1469).—Addition of rubidium and cæsium sulphates to a nutritive solution containing sucrose (10), asparagine (0·1), peptone (0·025), monopotassium phosphate (0·1), and magnesium sulphate (0·025%) increased the yield of yeast, whilst lithium chloride and sulphate were injurious rather than beneficial. Potassium is essential; as much as 4·0% of monopotassium phosphate may be present without injurious effects. Ammonium salts up to 2% may be employed without injuring yeast. N. H. J. M.

Biochemical Synthesis of Alkyl Glucosides (α-Glucosides) by means of α-Glucosidase : α-Methyl Glucoside. Destruction of the α-Glucosidase in a Strongly Alcoholic Medium. ÉMILE BOURQUELOT, HENRI HÉRISSEY, and MARC BRIDEL (*Compt. rend.*, 1913, **156**, 491—493; *J. Pharm. Chim.*, 1913, [vii], **7**, 233—236).—The authors have synthesised α-methyl glucoside by the action of

a-glucosidase, obtained from bottom yeast (compare this vol., i, 323), on a solution of dextrose in dilute methyl alcohol. The glucoside is readily hydrolysed in aqueous solution by the enzyme. Both the synthesising and the hydrolysing influence of *a*-glucosidase are destroyed by contact for forty-eight hours at 15—18° with 60% methyl alcohol. With 35% alcohol slow destruction also takes place.   W. G.

Action of Boron Compounds on the Growth of Plants. EMIL HASELHOFF (*Landw. Versuchs-Stat.*, 1913, **79–80**, 399—429. Compare Peligot, *Compt. rend.*, 1876, **83**, 686 ; Morel, A., 1892, 651 ; Loew, *Flora*, 1892. 374 ; Hotter, A., 1890, 1338 ; Nakamura, *Bull. Coll. Agric. Tokyo*, 1903. **5**, 509 ; Agulhon, A , 1910, ii, 236).—Small amounts of borax in water cultures (1 mg. per litre) acted favourably on the growth of plants, although the appearance of the plants indicated some injurious action. The same amount of boron in the form of borax diminished the yield. Both beans and maize are injured by 1·15 mg. per litre of boron.

In soil culture experiments, 0·125 mg. of boron (as borax) per kilo. of soil was not injurious to beans, whilst the same amount as boric acid is toxic. In some cases very small amounts (less than 0·1 per million of soil) seemed to have a stimulating effect.

The boron taken up by plants is deposited in the straw, and not in the seed. Although the production of spots on the leaves, under the influence of boron, seems to be the same in all kinds of plants, the effect on growth seems to vary with different plants.

                                                                    N. H. J. M.

The Value of the Chlorophyll Coefficients and their Relation to the Real Respiratory Coefficients. LÉON MAQUENNE and ÉM. DEMOUSSY (*Compt. rend.*, 1913. **156**, 506—512).—The authors have determined the respiratory quotient and the chlorophyll coefficient of some thirty-two species of plants, and as a result of this and previous work (compare A., 1912, ii, 1201) put forward a number of conclusions as to the conditions governing respiration and assimilation in the plant. In the case of green plants the normal respiratory quotient is generally greater than one during the total period of growth, but diminishes as the leaves grow older, its excessive diminution being a sign of decay or damage of the organs under observation. Leaves, with a respiratory quotient greater than one, increase the pressure of the air in which they breathe and vice versa. Certain species, particularly those rich in organic acids, are sensitive to prior conditions of light and temperature, exposure to strong light tending to diminish the respiratory quotient, but there is a particular state of equilibrium for each of such conditions, and to this, by adaptation, the plant tends to come. For a plant in equilibrium with external conditions there exists a simple relation between its apparent and real respiratory quotients and the composition of the medium in which it breathes and its coefficient of absorption for carbon dioxide, the cellular juice in a leaf sheltered from light being supersaturated with respect to the latter. The apparent chlorophyll-coefficient is generally intermedi-

ate between the respiratory quotient and unity, the real coefficient being very near to unity. Changes in the ratio hydrogen : oxygen in the composition of the vegetable tissues are due mainly, if not entirely, to respiration, and but little to assimilation. The variations of the real respiratory quotient, due to changes in temperature, arise from changes in the chemical composition of the vegetable tissues under the given conditions, the chlorophyll-coefficient being unaffected.   W. G.

Absorption of Oxygen by the Respiratory Chromogens of Plants. VLADIMIR I. PALLADIN and Z. N. TOLSTAJA (*Bull. Acad. Sci. St. Pétersbourg*, 1913, 93—108*).—Experiments with etiolated stems of *Vicia faba* and with zymin give the following results.

The protoplasm in which the respiratory chromogens effect absorption of oxygen possesses an alkaline reaction. These chromogens may be extracted from plants by means of methyl alcohol, and, in alkaline solution, are found to absorb oxygen eagerly from the air, with formation of a cinnamon-red pigment; peroxydases or hydrogen peroxide likewise cause oxidation of the chromogens. Aqueous extracts of plants also contain chromogens able to fix atmospheric oxygen, the power to do this being weakened or completely annulled by boiling the extracts.

Chromogens extracted by means of methyl alcohol undergo scarcely any oxidation in the air, but those obtained from plants subjected for some days to autolysis in an oxygen-free medium rapidly absorb oxygen from the air with development of pigments; the addition of hydrogen peroxide prevents the formation of pigment, the liquid remaining colourless. The chromogen modified by autolysis is hence termed "reducing." Autolysis with yeast converts ordinary chromogen into the reducing modification.

Plants which, after autolysis in absence of oxygen, give a chromogen rapidly blackening in the air, give no trace of pigment when the autolysis proceeds in presence of oxygen.

The respiratory chromogen from beans is probably catechol or some derivative of it.

Alcoholic fermentation is accompanied by the formation of a substance, which readily removes hydrogen from the respiratory chromogen, and oxidises it, by means of atmospheric oxygen, to water; this withdrawal of hydrogen from the chromogen is not prevented by boiling the products of fermentation.

Thus, the respiratory chromogen, $R \cdot H_2$, like leuco-compounds, gives up its hydrogen to the absorbed oxygen with formation of pigment, R, and water.

Palladin's previous statement that, during respiration of plants the carbon is oxidised, not by the oxygen of the air, but by water, is completely confirmed by the results of Wieland's investigations (A., 1912, i, 348, 944), which showed that the oxidation of aldehydes (intermediate products of alcoholic fermentation) may proceed by removal of oxygen from water with preliminary formation of hydrates. The removal of the hydrogen formed by the decomposi-

*and *Biochem. Zeitsch.*, 1913, 49, 381—397.

tion of the water, which in Wieland's experiments was effected by means of methylene-blue or quinonoid compounds, is brought about in the case of plants by the respiratory chromogens; according to Bach, the decomposition of the water is a result of the action of reducases.

It is quite probable that, in the oxidation of chromogen to pigment, water is not immediately formed, but that the first product is either hydrogen peroxide (compare Manchot, A., 1901, i, 565, 574; ii, 93) or an organic peroxide (Bach's oxygenase).

<div align="right">T. H. P.</div>

The Migration of Mineral Constituents and the Displacement of These Constituents in Leaves Immersed in Water. GUSTAVE ANDRÉ (*Compt. rend.*, 1913, 156, 564—566).—The author has estimated the mineral constituents in the dry matter of chestnut leaves plucked at various times during the summer of 1912. The figures, whilst varying in the same direction, differ considerably from the results obtained for 1911 (compare this vol., i, 233). The total nitrogen and phosphorus diminish with increase in age of the leaf, whilst the sulphur, calcium, magnesium, and potassium increase as the leaf grows older, the increase in sulphur and calcium being probably largely due to the accumulation of calcium sulphate in the leaf.

The figures for the percentage loss of mineral matter during immersion in water for one month are of the same order as those obtained for leaves grown in 1911 (*loc. cit.*), calcium being the most resistant to exosmosis.

<div align="right">W. G.</div>

The Germination of Seeds which have been Chemically Treated and Exposed to Light. FRIEDRICH SIMON (*Biochem. Zeitsch.*, 1913, 48, 410—417).—Seeds of various plants (cress, oats, radishes) were allowed to germinate after treatment with ferric and uranyl sulphates, both when kept in the dark after the action of the reagent, and when exposed to sunlight. The percentage of the number of plants which germinated after five days was determined and compared with the number of seedlings obtained from seeds which had not been chemically treated, some of which had been exposed to light, and others kept in the dark. The results are tabulated, and it was found that in some cases (but by no means all) the seeds which had been exposed to light germinated more than those which had been kept in the dark. The action of the light and chemicals differed, however, in the different varieties of seed.

<div align="right">S. B. S.</div>

Alleged Constant Occurrence of Iodine in Cells. JOHANNA BABIY (*Ber. deut. bot. Ges.*, 1913, 31, 35—47).—The examination of numerous plants for iodine gave negative results invariably. Further experiments were made to ascertain whether plants absorb iodine from solutions containing potassium iodide. The results were negative.

The conclusion drawn by Justus (A., 1902, ii, 311) that iodine

is always present in the cell nucleus, animal and vegetable, is therefore incorrect.   N. H. J. M.

Formation of Carbamide by Higher Plants. ROBERT FOSSE (*Compt. rend..* 1913, **156**, 567—568. Compare A., 1912, ii, 1203).— Carbamide has been found in wheat, barley, maize, peas, clover, and beans, germinated under conditions excluding the presence of carbamide in the medium. Its presence has been proved in the seed during germination, but with the seed in a state of repose a negative result was obtained in the case of the white lupin and the bean, and a positive result with wheat, maize, and peas. In the case of the bean, after six weeks' germination no carbamide could be detected in the cotyledon, but it was found in the plumule to the extent of 0·112 gram per kilo. of fresh material. It was also present in the embryo of the haricot. Finally, its presence has been proved in the plumule of maize, aseptically germinated, and in the adult plant developed on a sterile, nutritive liquid according to Mazé's method.   W. G.

Presence of Callose in the Membrane of the Marine Siphonaceous Algæ [Siphonates]. ROBERT MIRANDE (*Compt. rend.*, 1913, **156**, 475—477).—The membrane of the *Caulerpa* contains no true cellulose, but is composed of two substances, one belonging to the group of pectins and the other to the calloses. This holds good for all the *Siphonates* with the exception of the *Vaucheriaceae*, which possess a celluloso-pectic membrane. The *Siphonates* thus form a distinct group, not only by reason of their anatomic characteristics, but by the chemical constitution of their membrane.
                                   W. G.

Influence of Temperature on the Development of Active Principles in Some Medicinal Plants. JAMES BURMANN (*Bull. Soc. chim.*, 1913, [iv], **13**, 246—248. Compare A., 1912, ii, 379).— By a comparison of the quantities of active principles present in colchicum, digitalis (*D. ambigua* and *D. purpurea*), aconite, and belladonna plants gathered under the same conditions each year from 1907–11 with the mean temperature prevalent during each year, the author is led to the conclusion that the alkaloidal or glucosidic content of a plant is a function of the mean temperature of the year during which it was grown.   H. W.

Production of Oxalic Acid by Aspergillus niger. CARL WEHMER (*Centr. Bakt. Par.*, 1913, ii, **37**, 31—33).—Polemical against Buromski (this vol., i, 230), with special reference to the methods used for the estimation of oxalic acid in cultures.   H. B. H.

Calotropis procera. A New Digitalis-like Drug. LOUIS LEWIN (*Arch. expt. Path. Pharm.*, 1913, **71**, 142—156).—A full botanical account is given of the plant, one of the Asclepiadeæ. The active principle is called calotropin, but it has not yet been prepared pure for chemical analysis. The main fact is expressed in the title, namely, that it belongs to the drugs which act on the heart like digitalis.   W. D. H.

Enzyme Action. IV. Occurrence of a Urease in Castor Beans. K. GEORGE FALK (*J. Amer. Chem. Soc.*, 1913, **35**, 292—294. Compare Falk and Nelson, A., 1912, i, 523, 593; Falk and Hamlin, this vol., i, 303).—In continuation of a study of the enzymes of the castor bean, the presence of a urease has been demonstrated, which is rendered inactive by heat.   E. G.

Constituents of the Seeds of Croton tiglium. ERNST WINTER-STEIN and M. A. JEGOROV (*Landw. Versuchs-Stat.*, 1913, **79–80**, 535—539).—The seeds examined contained 5—10% of nitrogen as proteins, and 0·19 and 0·19% of nitrogen as bases and amino-acids respectively. The proteins yield the usual cleavage products. When the seeds, freed from fat, are kept for sixteen days at 37—40° in presence of toluene, chloroform, and some sodium fluoride, xanthine bases, arginine and lysine are produced. The solution from the lead acetate precipitate contained the following amounts of nitrogen: as bases, 1·437; as ammonia, 0·3514; and as amino-acids, 1·7648 grams (from 500 grams of seeds).   N. H. J. M.

The Acids of Fungi. E. HERRMANN (*Chem. Zeit.*, 1913, **37**, 206). —Oxalic, fumaric, and malic acids are widely distributed in fungi, and usually occur as calcium salts. Oxalic acid, supposed to be derived by oxidation of carbohydrate, is the commonest. Malic acid is sometimes found as potassium salt. Fatty acids also occur in fungi, particularly palmitic acid. Formic, acetic, and butyric acids are characteristic of individual species. Ergotic and sclerotic acids are characteristic of ergot. Telephoric acid, present in the cuticle of some fungi, is a pigment.   E. F. A.

Composition of Some Fungi, and the Products of Their Autolysis. ERNST WINTERSTEIN, C. REUTER, and R. KOROLEV (*Landw. Versuchs-Stat.*, 1913, **79–80**, 541—562).—The fat of *Boletus edulis* contains 0·52% of a cholesterol, m. p. 160°; $[a]_D$ −133° in 5% chloroform solution. The following substances were obtained from the fungus: inactive alanine, valine, phenylalanine, small amounts of amino-acids and trimethylamine, guanine, adenine, hypoxanthine, trimethylhistidine, and tetramethylenediamine.

In the autolysis of *Boletus*, 80—90% of the total dry matter becomes soluble; the insoluble portion contains little nitrogen. The solution contained small amounts of guanine, some hypoxanthine, but no adenine or histidine. Trimethylhistidine, much tetramethylenediamine and *iso*amylamine, and a great deal of ammonia were found.

Agaricus campestris, *Cantharellus cibarius*, and *Craterellus cornucopioides* were also subjected to autolysis.

The results show that the proteins of fungi are to a great extent decomposed into their simple crystalline cleavage products, and probably peptones and polypeptides as well. It is probable that autolytic processes occur in the symbiosis of root-nodules (compare Shibata, *Jahrb. wiss. Bot*, **37**, 643).   N. H. J. M.

The Presence of Gentiopicrin, Gentianose, and Sucrose in the Fresh Roots of Gentiana punctata. MARC BRIDEL (*Compt. rend.*, 1913, **156**, 627—629; *J. Pharm Chim.*, 1913, [vii], **7**, 289—292. Compare this vol., i, 149).—The author has isolated in a pure, crystalline state, and characterised, gentiopicrin, gentianose, and sucrose from the fresh roots of *Gentiana punctata*, and has also obtained evidence of the presence of a supposed new sugar. W. G.

Formation of Acetaldehyde during the Anaërobic Respiration of Poplar Blossom. S. KOSTYTSCHEV, ELISE HUB-BENET, and A. SCHELOUMOV (*Zeitsch. physiol. Chem.*, 1913, **83**, 105—111. Compare Palladin and Kostytschev, A., 1906, ii, 696).—Considerable quantities of freshly gathered poplar blossoms were kept in a stream of hydrogen, and the carbon dioxide, alcohol, and other volatile products formed were measured. The ratio of $CO_2 : C_2H_6O$ during respiration varied from $1.00 : 35$ to $100 : 55$, and differed from that obtained in alcoholic fermentation. In addition, acetaldehyde is formed. The amount of sugar in the fresh flowers is not large, and it is almost entirely used up during the experiment. The excess of carbon dioxide formed over that produced during alcoholic fermentation is attributed to the decomposition of other substances. The formation of acetaldehyde is considered to be due to the oxidation of active hydrogen attached to reductase and consequent partial retardation of the reduction of acetaldehyde to alcohol (compare this vol., i, 323).   E. F. A.

A New Rhubarb from Altai. ALEXANDER TSCHIRCH and M. RUSZKOVSKI (*Arch. Pharm.*, 1913, **251**, 121—136. Compare A., 1905, ii, 851; 1907, ii, 501; and Tutin and Clewer, T., 1911, **99**, 946).—A proximate analysis of roots from an unidentified species of rheum collected at Altai shows that it belongs to the "rhaponticum" group. The constituents observed are rhaponticin, chrysophanol, emodin methyl ether, emodin, dextrose, tanno-glucosides, and anthraglucosides; the last two groups of substances yield respectively rheum-red and rheonigrin on hydrolysis by acids. Rhein is absent.   T. A. H.

The Oil Seed of Ximenia Americana, L. F. SCHRODER (*Arb. Kais. Gesund*, 1912, **43**, 454—474).—An account of the constituents is given. The seeds consist of 32·3% shell, and 67·6% kernel; the latter contains 2·99% moisture, 66·0% fat, 15·2% proteins, 3·0% crude fibre, 2·19% ash, and 10·46% nitrogen free extract. No saponin, alkaloid, or cyanogenetic glucoside was found. The kernels also contain about 1% of a caoutchouc-like substance, which yields a tetrabromide. The oil varies a little in physical properties depending on the method of preparation; it is yellow, semi-solid, possesses a sharp after-taste, and has the following constants: D^{15} 0·9205 to 0·9220; saponification number, 173·2 to 177·0; iodine number, 80·3 to 85·05; Hehner number, 93·9 to 94·8; Reichert Meissl number, 1·61 to 2·45; Polenske number, 0·12 to 0·21; un-saponifiable matter, 0·46 to 0·55%. The viscosity in Engler degrees varied from 19·2 to 37·1 at 25°, and from 6·6 to 11·3 at 50°, the

highest value in each case being for oil extracted by ether, and the lowest for oil extracted by acetone. The total fatty acids included 75% of liquid fatty acids, and 10% of arachidic acid.

The shell contained 1·07% moisture, 5·9% fat, 9·05% proteins, 24·83% crude fibre, 12·78% ash, and 46·32% nitrogen-free extract.

T. A. H.

Biochemistry of Sea Weeds. HARALD KYLIN (*Zeitsch. physiol. Chem.*, 1913, **83**, 171—197).—Fucosan, the constituent of the bladders of the *Fucoideæ* which is coloured red by vanillin and hydrochloric acid, has strong reducing properties; it is precipitated by lead acetate and in acid solution by gelatin solutions. Its solutions have an adstringent taste resembling tannin. On oxidation, phycophæin is obtained. No sugar is eliminated on boiling fucosan with dilute sulphuric acid.

Mannitol has been found in several *Fucus* and *Laminaria* species The sweet-tasting, white substance, which often covers the whole thallus of *Laminaria* on drying, is mannitol.

Dextrose or lævulose were found in small quantity in four of the *Fucoideæ* investigated, but in none of the *Florideæ*. Several of the *Fucoid-æ* contain also a dextrin-like polysaccharide, laminarin, which is regarded as a reserve material built up from dextrose and corresponding with starch in the higher plants.

Two species, *Ascophyllum nodosum* and *Fucus vesiculosus*, which contain fat, contained very little laminarin.

The *Florideæ* contain starch, which gives dextrose when boiled with dilute acids, and is quickly hydrolysed by malt diastase.

The seaweeds are rich in slimy cell-wall constituents. Algin and fucidin, obtained from the *Fucoideæ*, are described briefly, as well as similar products from the *Florideæ*.   E. F. A.

Nutrition of Green Plants with Ammonium Salts. ENRICO PANTANELLI and G. SEVERINI (*Bied. Zentr.*, 1913, **42**, 98; from *Staz. sper. agrar. ital.*, 1911, **44**, 873).—Sand-culture experiments in which wheat and mustard were supplied with different ammonium salts under sterilised conditions. Sodium nitrate was also employed.

The greatest amounts of leaf were obtained with sodium nitrate, whilst ammonium salts produced the greatest amount of seed.

The only injurious effects were observed when ammonium chloride was employed, and in the case of mustard, with ammonium citrate. The best results with wheat were obtained with the organic ammonium salts, then the insoluble ammonium magnesium phosphate, and next with sodium nitrate. Mustard developed most quickly under the influence of sodium nitrate.   N. H. J. M.

Changes of Phosphoric Acid in Plants at Different Periods of Growth and with Different Phosphorus Manures. LEOPOLD SEIDLER (*Landw. Versuchs-Stat.*, 1913, **79—80**, 563—610).—Pot experiments in which barley and oats were grown in different soils, without phosphorus and with superphosphate, bone meal, and basic slag respectively.

The result obtained by Staniszkis with millet, indicating that the nitrogen increases in the parts above ground to the end, was partly confirmed. In the roots, however, there is a diminution in the amount of nitrogen. The amount of phosphoric acid taken up is not always in proportion to the production of dry matter. Inorganic phosphates which, at first, are taken up in considerable amounts are, as vegetation proceeds, to a great extent converted into organic phosphorus compounds. In barley the organic phosphorus is chiefly in the forms of protein and lecithins, whilst in oats phytin frequently predominates. The phosphoric acid of phytin, which generally forms only a fraction of the total phosphoric acid, increases in the whole plant to the end of the vegetative period; in the roots it generally diminishes.

As regards the relation between the inorganic and organic phosphorus, the latter increases in barley, and generally in oats, as vegetation proceeds; in oats, however, the amount of organic phosphorus generally remains less than the inorganic phosphorus.

N. H. J. M.

The Significance of the Lime–Magnesia Ratio in Soil Analyses. P. L. GILE and O. N. AGETON (*J. Ind. Eng. Chem.*, 1913, **5**, 33—35).—Loew has put forward the hypothesis that plants make their maximum growth, other factors being favourable, only when the available lime and magnesia are present in a ratio which may vary from 1:1 to 4:1. The authors have made observations on Porto Rican soils, and obtained very conflicting results, finding that soils with lime-magnesia ratios varying from 30:1 to 500:1 are productive pineapple soils; that one soil with the ratio 25:1 is an exceptionally productive soil for citrus fruits and pineapples; that another soil, where the ratio varies from 22:1 to 1461:1 is an exceptionally productive soil for sugar cane.

It may be that the apparently confirmatory results arrived at by some investigators are to be attributed rather to alterations in the soil reaction than to the lime-magnesia ratio. It would appear that in analyses of ordinary soils the above ratio is of no significance, but in analyses of the soluble salts of alkali soils the ratio may be exceedingly important. T. S. P.

Weathering of Soil. G. H. LEOPOLD (*Chem. Weekblad*, 1913, **10**, 70—86).—An investigation of the conditions affecting the formation of various types of soil by weathering, based on a large number of analyses of dark grey and red loams. A. J. W.

Two Volcanogenic Loams from Japan. TOYOTARO SEKI (*Landw. Versuchs-Stat.*, 1913, **79-80**, 871—890).—Analyses of two loams from Tokio and from North-East Japan. The soils possess only a slight plasticity when kneaded with water, and are friable when dry. The soils do not contain zeolites, and their deficient plasticity is attributed to the absence of aluminium hydroxides and to the presence of allophanoids. N. H. J. M.

Organic Chemistry.

Some Data of the Solubility of Metallic Copper in the Different Fractions Obtained by the Distillation of Crude Petroleum. CONSTANTIN I. ISTRATI and C. TEODORESCU (*Bull. Acad. Sci. Roumaine*, 1912/3, **1**, 19—25).—The requisite petroleum was obtained by fractionating crude petroleum taken from the Moreni reservoir. Eight fractions were collected, the extreme values of the b. p. being 100° and 300° respectively, each fraction having a range of b. p. of 25°. The separate fractions were placed in sunlight after addition of an excess of purely divided metallic copper. In general, the amount of copper salt formed increased with increasing b. p. of the fraction, the values observed varying from 0·022 gram per 100 c.c. for fraction b. p. 100—125° to 3·499 grams per 100 c.c. for fraction b. p. 275—300°. A notable exception to this regularity occurs with the portion of b. p. 250—275°, which dissolves less copper than either the preceding or succeeding fraction. Determination of the acidity of these fractions, whether by extraction with alcohol or by direct estimation with alcoholic potassium hydroxide, shows that this factor increases regularly with increasing b. p. of the fractions. The authors are led to the conclusion that this apparent anomaly is due to the presence of a larger proportion of lactones in the fraction b. p. 250—275°, which, although capable of neutralising alkali, are unable to attack metallic copper. This view is confirmed by the fact that a greater quantity of lactones can be extracted by means of alcohol from the fraction b. p. 250—275°, which has been treated with metallic copper, than from a similarly treated fraction, b. p. 225—250°.　　　　H. W

The Composition of Illuminating Gas. PAUL LEBEAU and A. DAMIENS (*Compt. rend.*, 1913, **156**, 797—799).—Combining the ordinary methods of gas analysis with their own methods for analysing mixtures of gaseous hydrocarbons (this vol., ii, 253), the authors have made very complete analyses of three different samples of illuminating gas, and their results, which are tabulated, establish the presence of higher homologues of methane. Their values for carbon monoxide are somewhat lower than the generally accepted figure for that constituent.　　　　W. G.

Mechanism of the Transformation of Stereoisomeric Ethylene Compounds. RICHARD STOERMER (*Chem. Zentr.*, 1913, i, 693—694; from *Sitzungsber. Abh. Naturforsch. Ges. Rostock*, 1912, **4**, 35—43).—The transformation of stable ethylene compounds into labile stereoisomerides by means of ultraviolet light (A., 1911, i, 295) cannot be explained by the theories of Wislicenus, Nef, or Aschan. Only Werner's conception of the carbon atom offers any assistance, and this has now been developed so as to include *cis-trans*-isomerism in ring compounds.　　　　J. C. W.

Elimination of Water from Pinacolyl Alcohol and on Tertiary Butylethylene. W. FOMIN and N. SOCHANSKI (*Ber.*, 1913, **46**, 1219. Compare this vol., i, 331).—The hexylene which Delacre obtained by the action of sodium on the chloride, $CMe_3 \cdot CCl{:}CH_2$ (A., 1906, i, 476), was also *tert.*-butylethylene ($\gamma\gamma$-dimethyl-Δ^β-butylene). The hydrocarbon, "pseudo-butylethylene," b. p. 56—58°, which accompanied the $\beta\gamma$-dimethyl-Δ^β-butylene (Couturier, A., 1893, i, 244) had in the meantime been identified as $\beta\gamma$-dimethyl-Δ^α-butylene.   J. C. W.

Preparation of $\beta\gamma$-Dimethyl-$\Delta^{\alpha\gamma}$-butadiene. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 256717).—It is found that the yield of $\beta\gamma$-dimethyl-$\Delta^{\alpha\gamma}$-butadiene obtained from pinacone or pinacolin (A., 1911, i, 829) can be increased to 80% if the operation is carried out at 450° and under reduced pressure.   F. M. G. M.

Preparation of Diolefines. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 255519).—When monohalogenated olefines, dihalogenated paraffins or halogenated alcohols are heated at 300—500° at ordinary or reduced pressures with catalytic agents, such as barium chloride, nickel chloride, lead chloride or aluminium hydroxide, they furnish satisfactory yields of the corresponding diolefines, and the preparation of isoprene by this method from the following substances is now recorded.

From (1) $\beta\gamma$-dibromo*iso*pentane, $CMe_2Br \cdot CHBrMe$, (2) $\beta\gamma$-dichloro*iso*-pentane, (3) $\alpha\gamma$-dibromo*iso*pentane, $CMe_2Br \cdot CH_2 \cdot CH_2Br$, (4) $\alpha\beta$-dibromo-*iso*pentane, $CHMe_2 \cdot CHBr \cdot CH_2Br$, (5) γ-bromo-β-methyl-Δ^β-butylene, $CMe_2{:}CMeBr$, (6) β-chloro-β-methylbutan-γ-ol, $CMe_2Cl \cdot CHMe \cdot OH$, (7) from the acetate of γ-bromo-β-methylbutan-α-ol,
$$OAc \cdot CH_2 \cdot CHMe \cdot CHBrMe,$$
whilst $\beta\gamma$-dibromobutane, $CHMeBr \cdot CHBrMe$, furnishes divinyl, hexylene dibromide gives rise to hexadiene, b. p. 68—77°, and dichloro-*n*-pentane yields $\Delta^{\alpha\gamma}$-pentadiene, b. p. 38—45°.   F. M. G. M.
The Action of Monosodioacetylene on the Alkyl Iodides. Preparation of True Acetylenic Hydrocarbons. PAUL LEBEAU and MARIUS PICON (*Compt. rend.*, 1913, **156**, 1077—1079).—Mono-sodioacetylene, prepared by the action of acetylene on sodium dissolved in liquid ammonia, when dissolved in the same solvent readily reacts with the alkyl iodides, giving the corresponding acetylene hydrocarbons, in nearly theoretical yield. The ammonia is removed by absorption with water, the last traces being eliminated by dilute sulphuric acid. By this method the authors have prepared allylene and hexinene.
                                                    W. G.

Preparation of Primary Alcohols by Reduction of the Esters with Absolute Alcohol and Sodium-ammonia. E. CHABLAY (*Compt. rend.*, 1913, **156**, 1020—1022).—Sodium in liquid ammonia reacts with esters of monobasic acids according to the equation : $3R \cdot CO_2R' + 4NH_3Na = 2R \cdot CONH_2 + R \cdot CH_2 \cdot ONa + 3R' \cdot ONa + 2NH_3$ (compare A., 1912, i, 244). Coupling this with the action of absolute alcohol on the sodium, giving nascent hydrogen, the

amide in its turn is converted into the corresponding primary alcohol, the whole of the acid being thus reduced to primary alcohol:
$$2R \cdot CO \cdot NH_2 + 4H_2 = 2R \cdot CH_2 \cdot OH + 2NH_3.$$
The ester dissolved in absolute alcohol is poured on to the solution of sodium in ammonia at $-80°$. When the action is complete, the residue is decomposed by water, distilled in steam, and the mixture of alcohols separated by fractionation. The corresponding alcohols have thus been prepared from the esters of a number of the higher fatty acids. The esters of dibasic acids are similarly reduced, giving dihydroxy-alcohols; methyl sebacate gives decane-$\alpha\kappa$-diol, m. p. $71 \cdot 5°$. Ethyl phenylacetate gives phenylethyl alcohol, whilst methyl cinnamate gives, not cinnamyl alcohol, but the saturated phenylpropyl alcohol.   W. G.

New Methods of Spirit Rectification. HUGO MASING (*Chem. Zeit.*, 1913, **37**, 329—330).—It has hitherto been usual to dilute the raw spirit with water before submitting it to the process of rectification. It has been found in Russia, however, that better results are obtained when the undiluted spirit is used. In order to find out the reason, the author has constructed a special still-head, a modification of the Le Bel and Henninger form, in which there are taps to the side-tubes so that the liquid flowing from any one of the bulbs can be collected for analysis.

The results show that the strength of the spirit collecting in the bulbs increases more slowly than according to Gröhning's tables (compare A., 1908, i, 751), the slowest rate of increase being with the very dilute spirit. The Russian method of rectification is therefore justified.   T. S. P.

$\beta\gamma$-Dimethylbutan-α-ol. ALEXANDER I. GORSKI (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 167—169).—Ethyl $\alpha\beta$-dimethylbutyrate, $C_8H_{16}O_2$, has b. p. 148—$150°/745$ mm., $D_4^{17} \; 0 \cdot 8719$, $D_4^{27 \cdot 3} \; 0 \cdot 8647$, $n_D^{18} \; 1 \cdot 4048$.

$\beta\gamma$-Dimethylbutan-α-ol, $C_6H_{14}O$, obtained by reducing the above ester by means of sodium in alcoholic solution, is a viscous liquid, b. p. 144—$145°/761$ mm., $D_4^{20 \cdot 5} \; 0 \cdot 8297$, $n_D^{20 \cdot 5} \; 1 \cdot 4195$, and forms a urethane, $C_{18}H_{19}O_2N$, m. p. 28—$29°$.   T. H. P.

New Data Concerning the Oxide of Pentamethylene Glycol. NICOLAI J. DEMJANOV (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 169—173).—Since the action of nitric acid on pentamethylene-diamine gives, in addition to pentamethylene glycol, a small proportion of an isomeric glycol, it is probable that the oxide obtained by the author (A., 1892, 1292) by heating pentamethylenediamine nitrite and by the action of sulphuric acid on the glycol prepared from pentamethylenediamine, and also that obtained by Hochstetter (A., 1903, i, 305) by the action of water on the bromide corresponding with the glycol from pentamethylenediamine, are not chemical individuals. Further, it is possible that the action of sulphuric acid on pure pentamethylene glycol may be accompanied by isomeric change, with formation of the oxide, $O{<}^{CHMe \cdot CH_2}_{CH_2-CH_2}$.

The author has therefore prepared the pure oxide by heating penta-methylene bromide in a sealed tube. This oxide, $C_7H_{10}O$, is a liquid, b. p. 86·5—87·5°/743 mm., D_0^{15} 0·883, D_0^0 0·900, n_D^{15} 1·4195, and on oxidation with nitric acid yields mainly succinic acid, its structure being thus confirmed. These properties agree closely with those given by Harries (A., 1911, i, 798) for his 3-methyltetrahydrofuran, and it may be that in the formation of this compound by the reduction of ethyl pyrotartrate, isomeric change occurs.   T. H. P.

Development of Heat on Mixing Ether and Chloroform. (Mme.) MARCELET and H. MARCELET (*Chem. Zentr.*, 1913, i, 229; from *Bull. Sci. Pharmacol.*, 1912, 19, 676—677).—Heat is developed when ether and chloroform are mixed, the maximum effect resulting from equal volumes; 25 c.c. of each liquid give a rise in temperature from 16·6° to 30·3°.   J. C. W.

The Constitution of Sulphurous Acid. WILHELM STRECKER (*Verh. Ges. deut. Naturforsch. Aerzte*, 1913, 126).—In continuation of previous investigations (A., 1910, i, 532), the sulphoxides have been prepared from symmetrical diethyl sulphite, and investigated optically. No details are given, but the conclusion arrived at from the optical results is, that there is no change in valency of the sulphur when a sulphoxide is oxidised into the sulphone; this is not in accordance with the chemical behaviour of these compounds.   T. S. P.

Decomposition of Formates. WILLIAM ŒCHSNER DE CONINCK and ALBERT RAYNAUD (*Rev. Gen. Chim. pure appl.*, 1912, 15, 455—456).—When sodium formate is heated, a complex mixture of substances is evolved containing aqueous vapour, aldehydes (among which acraldehyde has been identified, A., 1912, i, 527), oily substances, formic acid, and small quantities of carbon dioxide. The residue contains sodium carbonate, sodium hydroxide, and carbon.

Sodium, calcium, barium, potassium, and lead formates are decomposed to a greater or less extent when treated with pure methyl alcohol at its b. p. Formic acid was detected by distilling a portion of the alcohol and testing with silver nitrate solution after addition of water. When ethyl alcohol is substituted for methyl alcohol, very little decomposition is observed in the cases of sodium and calcium formates, whilst barium, potassium, and lead formates are rather more sensitive to the decomposing action of this reagent.

Solutions of lead formate, when exposed to diffused light during four months, are partly decomposed with the liberation of formic acid. Under similar conditions, uranium formate is completely decomposed in methyl-alcoholic solution within three months (compare this vol., i, 333).   H. W.

Catalytic Esterification in Dilute Solutions: Preparation of Ethyl Acetate. FERNAND BODROUX (*Compt. rend.*, 1913, 156, 1079—1081. Compare Senderens and Aboulenc, A., 1911, i, 600, 637; ii, 1080; 1912, i, 694).—By distilling mixtures of ethyl alcohol and acetic acid diluted with water containing varying quantities of sulphuric

acid, ethyl acetate is obtained, the yield of the ester from given quantities of alcohol and acid varying with the amount of sulphuric acid in the water. With 10% sulphuric acid, a yield of 92% of ethyl acetate is obtained. The sulphuric acid can be replaced by numerous other acids as catalysts, but they are less effective. W. G.

The Hydrolysis of Fats. JULIUS MARCUSSON (*Zeitsch. angew. Chem.*, 1913, **26**, 173—176).—It is now generally accepted that the hydrolysis of fats in a homogeneous system takes place in steps with intermediate formation of diglycerides and monoglycerides (Fortini, A., 1912, i, 826; Grün and Corelli, A., 1912, i, 409; Fanto and Stritar, A., 1908, i, 499, and others). The present state of knowledge of the process of hydrolysis in a heterogeneous system, for example, by alkali, is not so satisfactory (compare Marcusson, A., 1906, i, 924; 1907, i, 674). Kellner (A., 1909, i, 357, 548, 759) obtained indications of a graded hydrolysis by superheated steam, but unfortunately used natural palm-kernel oil, which, as a mixture of triglycerides, might give misleading results. The author has investigated the hydrolysis of simple triglycerides, such as tribenzoin, tristearin, and tripalmitin, by heating with water in an autoclave; after this treatment the triglyceride had a. m. p. several degrees lower, and in the case of the two latter fats, treatment with acetic anhydride (during which "aceto-lysis" did not occur; Willstätter and Madinaveitia, A., 1912, ii, 1104) gave a product which showed a considerably higher saponification number than the original triglyceride. Palm-kernel oil exhibited similar behaviour. From these results it appears that the hydrolysis of fats by water, and therefore presumably also by acids and enzymes, is a bimolecular process.

The author favours the view that the exceptional behaviour of alkali, which appears to hydrolyse directly to glycerol, is due to hydrolysis occurring mainly at the contact surface of fat and aqueous liquid; on account of the slow rate of diffusion of the intermediate diglycerides and monoglycerides, and the relatively great rapidity of their hydrolysis, no appreciable quantity of these substances can escape into the main body of fat again. In the above autoclave experiments, however, the elevated temperature increases the velocity of diffusion of the substances, whilst the hydrolysis is relatively much slower, so that the escape of the intermediate products from immediate further hydrolysis is facilitated. D. F. T.

Glycerides of Fats and Oils. IV. The Mixed Glycerides of Palmitic and Stearic Acids Obtained from Lard. ALOIS BÖMER (*Zeitsch. Nahr. Genussm.*, 1913, **25**, 321—353. Compare A., 1912, i, 600).—By repeated fractionation from ether, pure glycerides of saturated fatty acids were isolated from lard; the least soluble glyceride so obtained was found to be a palmityldistearin, and not heptadecyldistearin as stated by Kreis and Hafner. Tristearin is not present in lard. The palmityldistearin separated from lard had m. p. 68·5° (corr.), and differed in this respect and also in its crystalline form from the similar glyceride separated from mutton fat; the former is probably α-palmityldistearin, whilst that from mutton fat is β-palmityl-

distearin. The lard under examination contained about 3% of a-palmityldistearin, and about 2% of another saturated glyceride, namely, stearyldipalmitin, m. p. 58·2° (corr.).   W. P. S.

Glycerides of Fats and Oils. V. Nomenclature of Mixed Glycerides and the Synthesis of α Distearin and β-Palmityldistearin. ALOIS BÖMER and R. LIMPRICH (*Zeitsch. Nahr. Genussm.*, 1913, **25**, 354—366).—It is suggested that, in the case of mixed glycerides, where different fatty acid radicles are combined with the same glycerol molecule, the position of the fatty acid radicles should be denoted by the letters α, β, and γ respectively. In the preparation of α-distearin from α-dichlorohydrin and potassium stearate (compare A., 1903, i, 788) considerable quantities of tristearin are also formed ; again, tristearin and possibly stearyldipalmitin are produced together with β-palmityl-distearin when the latter is prepared from α-distearin and palmitic acid. α-Distearin has m. p. 78·5° (corr.), and β-palmityldistearin has m. p. about 63°, and is identical with the palmityldistearin separated from mutton fat.   W. P. S.

China Oil. SERGEI A. FOKIN (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 283—285).—The polymerisation of this oil when heated, the increased refraction, and the transformation of the elæomargaric acid under the influence of light into a product with a higher melting point are explainable on the assumption that the acid contains either conjugated double linkings or, as in allene, a carbon atom with two double linkings. The products obtained when the acid is oxidised with alkaline permanganate solution indicate its structure to be :

$$CH_3 \cdot [CH_2]_3 \cdot CH:CH \cdot CH:CH \cdot [CH_2]_9 \cdot CO_2H.$$ T. H. P.
Behaviour of Certain Unsaturated Acids Towards Selenious Acids. SERGEI A. FOKIN (*J. Russ. Phys. Chem. Soc*, 1913, **45**, 285—286).—Various unsaturated aliphatic acids and, more especially, the oils containing them as glycerides, undergo marked changes when heated with concentrated solutions of selenious acid at 100° under the ordinary pressure. This action is most characteristic in the case of castor oil. After one to three hours' heating, the oil becomes converted into a caoutchouc-like mass of a faint red colour. This product is insoluble in alcohol, ether, benzene, pyridine, etc., but it dissolves with decomposition in boiling acetic acid, and is saponified and darkened by alcoholic potassium hydroxide. When treated with alcohol or ether, it swells to a jelly, which can be readily pounded to a paste and, after evaporation of the alcohol or ether in the cold, reduced to powder. After being washed to remove any excess of selenious acid or castor oil, the powder has the iodine number 59·0 and the saponification number 168·5, the corresponding numbers for castor oil being 86 and 180 respectively. The substance contains selenium, and the presence of double linkings and the small difference between its saponification number and that of the original oil indicate it to be different from the "factis" obtained by the action of sulphur di- or tetra-chloride on linseed and other oils.   T. H. P.

Formation, Decomposition, and Transformation of Glycollic Acid. EMIL BAUR (*Ber.*, 1913, **46**, 852—863).—It is found that the reduction of oxalic acid to glycollic acid which can be effected by electrolytic reduction with lead, or less well with platinum, cathodes (A., 1908, i, 600), also occurs to some extent when a solution of oxalic acid with formic acid is submitted to the action of finely divided rhodium (Schade, A., 1908, i, 136; Blackadder, this vol., ii, 36) or of platinised platinum foil. The metal causes the decomposition of the formic acid into hydrogen and carbon dioxide, the former of which effects a reduction of the oxalic acid through glyoxylic acid to glycollic acid. Small quantities of the two last substances can be detected in the final mixture.

In the presence of coloured metallic salts, glycollic acid is affected by exposure to the light of a quartz mercury lamp, being partly converted into formaldehyde and formic acid. The following salts, copper sulphate, uranic and uranous sulphates, and ferric sulphate all exerted this effect, but the first-named was least active and the last-named most.

When tubes of quartz glass containing an aqueous solution of calcium glycollate or of a mixture of calcium glycollate and calcium malate are submitted to the light of a quartz-mercury lamp for one hundred and forty hours, a certain amount of calcium citrate is formed (compare Ciamician and Silber, A., 1911, i, 513, 650); the same condensation to citric acid occurs when saturated solutions of calcium glycollate or calcium malate, mixed with one and a-half times their bulk of saturated lime-water, are kept for a few days. Although it was not possible to prove the presence of a malate in the solution of calcium glycollate after exposure to light, the accidental growth of a mould in a solution of calcium glycollate caused the formation of minute crystals of calcium malate.

In connexion with his view that oxalic acid is the first product of assimilation of carbon dioxide in plants (A., 1908, ii, 780), the author draws attention to the manner in which the above results render oxalic acid a possible origin of the common vegetable acids; further, by its scission into formaldehyde and formic acid, glycollic acid may possibly be the source of the sugars. D. F. T.

Method of Preparing Ethyl γ-Chloroacetoacetate. DIMITRI K. ALEXANDROV (*Ber.*, 1913, **46**, 1021—1024).—By the interaction of magnesium powder with ethyl α-chloroacetate, a condensation product of two molecules, $CH_2Cl\cdot C(OEt)(O\cdot MgCl)\cdot CH_2\cdot CO_2Et$, is formed, which is decomposed by water into ethyl γ-chloroacetoacetate. This is a colourless oil, b. p. 107°/14 mm., giving a red coloration with ferric chloride, D_4^{20} 1·2157, n_D^{17} 1·4546. The copper salt crystallises in thin, matted, pale green needles, m. p. 168—169° (decomp.). E. F. A.

Action of Oxalyl Chloride on Several Organic Derivatives. HERMAN J. TAVERNE (*Chem. Weekblad*, 1913, **10**, 214—223. Compare Graebe and Liebermann, *Ber.*, 1869, **2**, 678; Staudinger, A., 1908, i, 938; 1909, i, 796, 905; 1912, i, 567; Jones and Tasker, T., 1909, **95**, 1904; Liebermann and Zsuffa, A., 1911, i, 202;

Liebermann, A., 1911. i, 656; 1912, i, 464; Bornwater, A., 1911, i, 616).—A summary of work on the reactions of oxalyl chloride previously published.   A. J. W.

Solubility of Thorium Oxalate. A. COLANI (*Compt. rend.*, 1913, **156**, 1075—1076. Compare Wirth and Hauser, A, 1912, i, 827).—A study of the solubility of thorium oxalate, alone or in the presence of oxalic acid, in hydrochloric acid at 17° and 50°. For varying concentrations of hydrochloric acid. the amount of oxalate dissolved is independent of the amount in contact with the liquid. With moderately strong acid, the oxalate is converted into chloro-oxalate with the elimination of oxalic acid, which consequently diminishes the solubility of the chloro-oxalate. The solubility of the thorium oxalate in hydrochloric acid is greatly diminished by the presence of small amounts of oxalic acid.   W. G.

Preparation and Properties of the Ammonium Salts of Some Organic Acids. LeRoy McMaster (*Amer. Chem. J.*, 1913, **49**, 294—301).—Keiser and McMaster (this vol., i, 248) have described a method for the preparation of normal ammonium salts of dibasic organic acids. In continuation of this work, ammonium *malonate,* succinate, *malate, tartrate,* phthalate, and iso*phthalate* have been prepared. The method has also been used for obtaining the salts of certain monobasic acids, and ammonium *propionate,* iso*butyrate, palmitate, benzoate,* and *cinnamate* are described.   E. G.

Crystalline Form and Optical Properties of Magnesium Malate. O. I. MOROSCHKINA (*Bull. Acad. Sci. St. Pétersbourg*, 1913, 225—230).—Magnesium malate, $MgC_4H_4O_5 5H_2O$, crystallises in hemihedral forms of the rhombic system: $a:b:c = 0.7476:1:0.4096$ (compare Traube, A., 1899, i, 484). The etched figures and optical properties are described.   T. H. P.

Tetrolaldehyde (Δ^a-Butinal) and Some of Its Derivatives. PAUL L VIGUIER (*Ann. Chim. Phys.*, 1913, [viii], **28**, 433—536).—A résumé of the work accomplished, and already abstracted, on this subject since 1908.   T. A. H.

Catalytic Hydrogenation of Acetone. A. LASSIEUR (*Compt. rend.*, 1913, **156**, 795—797. Compare Haller and Lassieur, A., 1910, i, 355).—The hydrogenation of acetone by the method of Sabatier and Senderens at temperatures above 200° yields neither iso*propyl* alcohol nor a pinacone, but the principal product is methyl iso*butyl* ketone, together with a small quantity of valerone and some still more highly condensed products.   W. G.

Migration of the Chlorine in the Halogenated Ketones. EDMOND E. BLAISE (*Compt. rend.*, 1913, **156**, 793—795. Compare this vol., i, 11).—By the chlorination of methyl ethyl ketone in the presence of water and marble a mixture of three chlorinated ketones is obtained. The smallest fraction is dichloromethyl ethyl ketone, b. p. 31°/

33—34 mm. The second and largest fraction is chloromethyl α-chloro-ethyl ketone, b. p. 165° (compare Vladesco, A., 1892, 424). The third constituent is methyl α-dichloroethyl ketone (compare Favorski and Desbout, A., 1895, 497). On heating dichloromethyl ethyl ketone with a mixture of hydrochloric and acetic acids on a water-bath for six hours, 50% of it is conveited into chloromethyl α-chloroethyl ketone, one of the chlorine atoms having migrated. Increase in the amount of hydrochloric acid in the mixture facilitates the migration. W. G.

Reduction of Acetobromoglucose and Similar Substances. EMIL FISCHER and KARL ZACH (*Sitzungsber. K. Akad. Wiss. Berlin.* 1913, 311—317).—On reduction of acetobromoglucose by means of zinc dust and acetic acid at the ordinary temperature, a crystalline compound, $C_{12}H_{16}O_7$, is obtained, together with a molecule of acetic acid. The new compound, *acetoglucal*, takes up two atoms of bromine. On hydrolysis three molecules of acetic acid are eliminated, and *glucal*, $C_6H_8O_3$, a soluble viscid syrup, b. p. 170—185°/0·2 mm. pressure, is obtained. This behaves as an aldehyde, and forms oily hydrazones, but no osazones. It decolorises bromine in aqueous solution, and is decomposed by acids, giving an intense green pine-splinter reaction when heated with hydrochloric acid.

Provisionally the formula $\begin{matrix} CH \cdot CH(CH_2 \cdot OH) \\ CH \text{——} CH(CHO) \end{matrix} {>}O$ is suggested.

Acetobromogalactose and acetobromolactose behave similarly when reduced, but only oily products were obtained.

Acetoglucal has m. p. 54—55°, $[\alpha]_D^{20} - 13 \cdot 02°$. E. F. A.

Phytin. R. H. ADERS PLIMMER and HAROLD J. PAGE (*Biochem. J.,* 1913, **7,** 157—174).—Inorganic phosphates in phytin can be estimated by precipitation with ammonium molybdate in semi-normal nitric acid at room temperature. The calcium can be estimated by precipitation as calcium sulphate, but not as oxalate. The magnesium can then be estimated as pyrophosphate. There is great difficulty in removing the calcium from phytin in the preparation of phytic acid. The yield of inositol on hydrolysis of the latter is not quantitative; there is possibly another organic constituent in phytin. W. D. H.

Transformation of *l*-Arabinose into *l*-Ribose. WILLIAM ALBERDA VAN EKENSTEIN and JAN J. BLANKSMA (*Chem. Weekblad,* 1913, **10,** 213—214).—Heating with dilute aqueous sodium hydroxide partly converts *l*-arabinose into *l*-ribose, the presence of the latter in the mixture being proved by oxidising the two pentoses to arabonic acid and ribonic acid, converting these acids into their phenylhydrazides, and separating the hydrazides by fractional crystallisation.

A. J. W.

Action of Hydrogen Peroxide and Ferric Chloride on Starch. O. DUBIEUX (*Bull. Soc. chim. Belg.,* 1913, **27,** 90—97. Compare Neuberg and Miura, A., 1911, i, 935; Gerber, A., 1912, i, 538).—Hydrogen peroxide solution does not hydrolyse soluble starch prepared by Fernbach's method at the ordinary temperature, and the

same is true of colloidal solutions of iron or of mixtures of these two products. Similarly, a solution of ferric chloride does not hydrolyse starch, but when used along with hydrogen peroxide it causes hydrolysis at an appreciable rate, which increases with the quantity of ferric chloride employed. The results of experiments designed to test the influence of various factors on the reaction show that the quantity of reducing substances formed depends on the quantity of peroxide used, and that the acidity of the mixture increases with the quantity of reducing substances formed. The hydrogen peroxide is decomposed, but no oxygen is evolved unless the peroxide is present in excess. The iron remains in the ferric state until hydrolysis is complete, when it suffers reduction, the reducing substances disappearing at the same time. Measurements of the rate of hydrolysis show that the reaction does not follow the logarithmic law for a unimolecular reaction. Hydrogen peroxide reduces the rate of hydrolysis of starch by diastase and does not undergo decomposition itself.   T. A. H.

Starch of Glutinous Rice and Its Hydrolysis by Diastase. Yoshio Tanaka·(*J. Ind. Eng. Chem.*, 1912, 4, 578—581).—The starch of glutinous rice is characterised by giving a red coloration with iodine ; the microscopic characteristics of these starch granules and the hydrolysed products do not apparently differ in any way from those of common rice starch. The starch of glutinous rice does not contain amylodextrin, erythrodextrin, or the special proteins which have previously been considered to be the cause of the red iodine coloration ; nor does it contain any of the common starch, which gives a blue colour with iodine.

Glutinous rice starch is, moreover, rapidly hydrolysed by diastase to dextrin with the production of a less amount of maltose than in the case of equal quantities of potato or common rice starch ; the author considers that glutinous rice starch contains a larger amount of amylopectin, or some analogous constituent which produces a dextrin that hydrolyses more slowly with diastase than does that from ordinary starch.

It is probable that there are many other cereals in Nature containing a similar variety of starch, its presence having been noted in glutinous millet, glutinous *Panicum miliaceum*, L., and in *Andropogon Sorghum*. The separation of glutinous from common rice starch is comparatively simple, as the former is opaque, the latter translucent.
F. M. G. M.

The Acetolysis of Cellulose to Dextrose Acetate. Hermann Ost (*Verh. Ges. deut. Naturforsch. Aerzte.*, 1913, 124—125).—The end-product of the acetylation of cellulose is cellobiose octa-acetate (compare A., 1912, i, 680), which is readily obtained in a pure crystalline condition when a mixture of 5 grams of cellulose with 25 c.c. of acetic anhydride and 2·5 grams of concentrated sulphuric acid is kept at the room temperature for some days, or even weeks ; the yield is 33%. The reaction proceeds farther on warming. For example, a mixture of 5 grams of cellulose, 25 c.c. of acetic anhydride, 25 c.c. of glacial acetic acid, and 5 grams of concentrated sulphuric acid when heated

for three days at 45° no longer gives cellobiose octa-acetate ; by extraction with ether, a syrup consisting of a mixture of dextrose penta-, tetra-, and tri-acetates is obtained, which by further acetylation can be transformed into dextrose α-penta-acetate, m. p. 112°, and a rotation of +101·7°. The same product can be obtained directly from cellobiose octa-acetate.

The results confirm the conclusion already drawn by Ost and Wilkening that the cellulose molecule is built up exclusively from dextrose residues. T. S. P.

Nitrocellulose. H. TEDESCO (*Zeitsch. ges. Schiess-Sprengstoffwesen*, 1912, **7**, 474—477).—An account of numerous experiments on various methods of preparing nitrocellulose, with special regard to the varying nitrogen content and stability of the products obtained under different conditions, such as varying the relative concentrations of the acids employed, the time allowed, and the temperature at which nitration is carried out, and employing different forms of cellulose for the experiments. F. M. G. M.

Soil Humus. SHERMAN LEAVITT (*J. Ind. Eng. Chem.*, 1912, **4**, 601—604).—Two methods of preparing samples of humus are fully described, and the following facts are emphasised.

(1) Two methods were employed for the removal of clay : (*a*) Mooers and Hampton's method; (*b*) mechanical separation, without evaporation to dryness.

(2) Indications were obtained of the relative behaviour of ferric iron, ferrous iron, and calcium in the retention of humus from water solution.

(3) Protein or protein-like substances were present in the humus examined.

(4) A starch-like substance was present which can be hydrolysed by acids, acted on by diastase with subsequent acid hydrolysis, and both processes gave reducing sugars in comparable amounts in all samples of humus examined.

(5) One of these reducing sugars was obtained in crystalline form, but has not yet been fully identified.

(6) Pentosans were present in appreciable amounts in all samples of humus examined.

(7) Nitrogen, present probably as an amino-acid, was found in the 1% hydrochloric acid extract in all soils examined by the official method. F. M. G. M.

Action of Hypochlorous Acid on Tertiary Amines. JAKOB MEISENHEIMER (*Ber.*, 1913, **46**, 1148—1161).—Willstätter and Iglauer (A., 1900, i, 458) have shown that dialkylchloroamines are formed by the action of hypochlorous acid on tertiary amines (compare also Hantzsch and Graf, A., 1905, i, 575). The authors have applied the reaction to simple tertiary amines, and are led to the conclusion that a trialkylamine dichloride is first formed, which rapidly decomposes with elimination of hydrogen chloride according to the scheme for trimethylamine : (i) $N(CH_3)_3 + Cl_2 = N(CH_3)_3Cl_2$;

(ii) $N(CH_3)_3Cl_2 = N(CH_3)_2(:CH_2)Cl + HCl$.

Dimethylmethylene ammonium chloride becomes transformed into formaldehyde and dimethylamine hydrochloride, the latter finally reacting with excess of hypochlorite, yielding dimethylchloroamine. This explanation differs from that given by Willstätter or Hantzsch in that two molecules of hypochlorous acid are required for each molecule of amine instead of one, and thus accounts for the fact that Willstatter and Iglauer obtained the best yields of chloronortropidine only by the use of two or more molecules of hypochlorous acid. Further, it involves the formation of aldehydes instead of alcohols as secondary products, and the production of large quantities of formaldehyde or acetaldehyde during the action of sodium or calcium hypochlorite on trimethylamine or triethylamine has been experimentally proved. Such aldehydes must be directly formed, since, under the conditions employed, alcohols are not oxidised to aldehydes. The assumption of the primary addition of chlorine appears at first sight to be improbable, since free chlorine does not convert tertiary amines into dialkylchloroamines to an appreciable extent. This is explained by the fact that two molecules of a tertiary amine are converted by one molecule of chlorine into a mixture of the hydrochlorides of the tertiary and secondary amines :

$$2N(CH_3)_3 + Cl_2 + H_2O = NMe_2H_2Cl + NMe_3HCl + CH_2O,$$
and that free chlorine does not react with salts of amines in the same manner as with the free amines.

No action occurs when the hydrochlorides of trimethylamine or triethylamine are mixed with aqueous solutions of free hypochlorous acid. With the free amines, dialkylchloroamines are formed in small quantity. Good yields of the latter substances can only be obtained by employing sodium hypochlorite or, better, bleaching powder.

An aqueous solution of trimethylamine hydrochloride was added to a cooled suspension of bleaching powder in water. On distillation, a mixture of dimethylchloroamine and methyldichloroamine was obtained, the latter being derived from decomposition of the former. Formaldehyde remained chiefly in the residue, and was identified by precipitation with p-nitrophenylhydrazine. Good yields of chloroamine were only obtained when a large excess of bleaching powder was used. Employment of sodium hypochlorite led to similar results. The yields, however, were uniformly less, and the best experimental conditions less readily ascertained. Nitrogen, nitric acid, and tetramethylammonium chloride were not formed.

Triethylamine hydrochloride in aqueous solution was similarly converted by an aqueous suspension of bleaching powder into a mixture of diethylchloroamine and ethyldichloroamine, which possibly contained a small quantity of chloroform. A large excess of bleaching powder was necessary, since, otherwise, the yields of chloroamine became very small. On the other hand, a portion of the triethylamine became then converted into diethylamine as was shown in experiments with sodium hypochlorite.

Triethylamine hydrochloride did not react with chlorine water, which, however, was decolorised by dimethylamine hydrochloride.

The reaction between triethylamine and chlorine water has been investigated. When the former was distilled into the latter, smaller

quantities of diethylamine hydrochloride and acetaldehyde were obtained than are required by the equation:

$$2NEt_3 + Cl_2 + H_2O = NEt_2HCl + NEt_2H_2Cl + C_2H_4O.$$
The authors consider that acid is formed in by-reactions which converts the tertiary amine into the corresponding salt, which is not acted on by chlorine. In a subsequent experiment, in which the amine was added in one portion to the chlorine water, a somewhat larger amount of aldehyde was detected.   H. W.

Preparation of Betaine from Molasses Residues. KARL URBAN (*Zeitsch. Zuckerind. Böhm.*, 1913, 37, 339—341).—To obtain betaine the evaporated molasses residues are mixed with an equal volume of concentrated hydrochloric acid. After cooling, the alkali chlorides which have separated are removed by filtration, and the filtrate is evaporated in a porcelain dish. The volatile organic acids and hydrochloric acid pass away, and humus substances are precipitated. These are also filtered off, and the residue further evaporated to a thick syrup. This is dissolved in water, filtered, decolorised by means of charcoal, and concentrated, when betaine hydrochloride separates out in a nearly pure state.   E. F. A.

Chemical Reactions Brought About by Sunlight. DOMENICO GANASSINI (*Chem. Zentr.*, 1913, i, 153—154; from *Giorn. Farm. Chim.*, 1912, 61, 439—444, 481—491).—Aqueous solutions of some mono- and di-basic amino-acids have been exposed to sunlight for three or four days, then treated with an excess of magnesium oxide, and left with red litmus paper. This soon became blue, whereas solutions which had been kept in the dark were without action. It was shown that glycine, alanine, asparagine, aspartic acid, and glutamic acid gradually decomposed into the corresponding aldehyde, ammonia, and carbon dioxide.   J. C. W.

⁍ Synthesis of the Natural Hydroxyproline Present in Proteins. Pyrrolidine Derivatives. IV. HERMANN LEUCHS and JOSEPH F. BREWSTER (*Ber.*, 1913, 46, 986—1000).—The preparation of hydroxyproline has been improved by treating $a\delta$-dichlorovalerolactone with ammonia instead of δ-chloro-a-bromovalerolactone.

γ-Hydroxyproline-(a)-phenylcarbimide is resolved by means of quinine. The synthetic l-γ-hydroxyproline derivative has $[a]_D^{20} - 37 \cdot 0°$, whereas the natural product has $[a]_D^{20} - 37 \cdot 2°$. This synthesis confirms the γ-position of the hydroxy-group and the structure assumed for the natural hydroxyproline.

The phenylcarbimide of hydroxyproline-(b) is also resolved by means of quinine, the ammonium salt having $[a]_D \pm 45°/d$. The active acid could not be obtained crystalline, but the corresponding hydantoins crystallise without difficulty.

To convert the γ-hydroxyproline-phenylcarbimide into the corresponding amino-acid, heating with concentrated hydrochloric acid in a sealed tube at 95° is necessary, but the product has lost its optical activity. To preserve this, the heating is carried out at 95° with aqueous ammonia, when γ-hydroxyproline and phenylcarbamide are

obtained. The synthetic *l*-hydroxyproline has $[a]_D^{20} - 76·3°$, whereas the only value available for the natural acid is $- 81°$.

The *quinine* salt of *hydroxyproline-phenylcarbimide* crystallises in needles or thin prisms, m. p. 206—209° (decomp.), $[z]_D - 37·2°$.

The corresponding *hydantoin* also crystallises in needles or thin prisms, m. p. 122—123°, $[a]_D^{20} - 50·4°$.

l-γ-*Hydroxyproline-phenylcarbimide*-(a) has m. p. 175°.

The corresponding derivative of γ-hydroxyproline-(*b*) does not crystallise, but the *hydantoin* forms lustrous, oblique prisms, m. p. 156—158°, $[a]_D^{20} - 55·2°$.   E. F. A.

A New Amino-acid of the Composition $C_6H_{13}O_2N$ Obtained by the Total Hydrolysis of the Proteins of the Nerve Substance. EMIL ABDERHALDEN and ARTHUR WEIL (*Zeitsch. physiol. Chem.*, 1913, **84**, 39—59. Compare A., 1912, ii, 1191).—The leucine fraction of the products of the complete hydrolysis of nerve proteins contains an amino-acid, $C_6H_{13}O_2N$, differing from either leucine,

$$CHMe_2·CH_2·CH(NH_2)·CO_2H,$$
or *iso*leucine, $CHMeEt·CH(NH_2)·CO_2H$, which is regarded as *d*-a-amino-hexoic acid, $CH_3·[CH_2]_3·CH(NH_2)·CO_2H$, and termed caprine. The existence of this isomeride in the nerve proteins was suggested by Thudichum, who did not determine its constitution. It is probable that it is present in other proteins. The ester of *d*-caprine has b. p. 91°/12 mm. d-*Caprine* itself has decomp. 285°, $[a]_D^{20} + 6·53°$ in water, and $+ 14·1°$ in 20% hydrochloric acid, and tastes faintly sweet. The corresponding *hydroxy-acid* crystallises in long, four-angled plates, m. p. 57°, $[a]_D^{20} - 4·68°$. The same acid prepared from the synthetic amino-acid forms slender, needle-shaped prisms, m. p. 60°, $[a]_D^{20} - 2·17°$, whereas the corresponding hydroxy-acid from *l*-leucine has m. p. 71°, $[a]_D^{20} - 16·37°$.   E. F. A.

Compounds of Guanylcarbamide and Guanylguanidine with Dextrose. LEOPOLD RADLBERGER (*Chem. Zentr.*, 1912, ii, 1963—1964; from *Österr. ung. Zeitsch. Zucker-Ind. Landw.*, 1912, **41**, 745—750).—Guanylcarbamide (dicyanodiamidine) forms a *chloride*, $C_2H_7ON_4Cl,\frac{1}{2}H_2O$, which is obtained in thin, colourless leaflets by evaporating the solution in concentrated hydrochloric acid over lime. The aqueous solution is neutral, and when rendered alkaline and boiled with a few drops of copper sulphate solution, develops a violet colour and deposits a rose-red *powder*, $C_4H_6O_2N_4Cu$, on cooling. Guanylguanidine (biguanide), may be purified by recrystallisation from alcohol (compare Bamberger and Dieckmann, A., 1892, 737). The chloride has the formula

$$C_2H_9N_5Cl_2.$$
The chlorides condense with dextrose in alcoholic solution. *Guanyl-carbamide-dextrose*,

$$OH·CH_2·[CH·OH]_4·CH:N·C(NH)·NH·CO·NH_2,HCl,$$
forms slender, microscopic needles, m. p. 107° (decomp.), $a_D^{20} + 0·2°$ (2% solution in alcohol, 2-dcm. tube), which reduce Fehling's solution and respond to the above test for guanylcarbamide. *Guanylguanidine-dextrose*, $OH·CH_2·[CH·OH]_4·CH:N·C(NH)·NH·C(NH)·NH_2,2HCl$, forms small needles which sinter at 116°, have a bitter taste, reduce

Fehling's solution, and give red needles of cuprobiguanide sulphate with ammoniacal copper sulphate. A 2% alcoholic solution in a 2-dcm. tube gives $a_D^{20} + 0.5°$. J. C. W.

Action of Sulphuric Acid on Dicyanodiamide Correction. HJALMAR LIDHOLM (*Ber.*, 1913, **46**, 1218. Compare this vol., i, 252).—The formula for dicyanodiamide was suggested by Bamberger (A., 1883, 907) and not by Pohl, and the reduction to guanidine was accomplished by Bamberger and Seeberger (A., 1893, 494).

J. C. W.

Colour Changes in Solutions of Cobaltous Thiocyanate. RAÚL WERNICKE (*Anal. Soc. Chim. Argentina*, 1913, **1**, 8—32).—Pure cobaltous thiocyanate was obtained by the action of an excess of the sulphate on alcoholic potassium thiocyanate, and repeated extraction and crystallisation of the cobalt salt by alcohol. Data of the conductivity and viscosity are given. The phenomena of colour-change are in general similar to those shown by the chloride. G. D. L.

Reduction of Sodium Nitroprusside by Hydrogen Sulphide. DOMENICO VENDITORI (*Atti R. Accad. Lincei*, 1913, [v], **22**, i, 162—167. Compare A., 1906, i, 486).—The reduction was effected by the action of an excess of hydrogen sulphide on a 10% solution of sodium nitroprusside kept on a water-bath for five or six hours. Hydrogen cyanide is evolved, and ultimately there results a solution (of nitrosulphide and ferrocyanide) and a precipitate (of sulphur and complex iron cyanogen compounds). As to the soluble products, 100 parts of nitroprusside yield about 13 parts of the nitrosulphide, $NaFe_4(NO)_7S_3$, and about 42 parts of sodium ferrocyanide. The yellowish-white precipitate becomes blue on exposure to the air; the yield of it is about 33% of the nitroprusside taken. When it is treated with warm concentrated hydrochloric acid, a blue powder remains undissolved, whilst the solution contains a green substance which can be re-precipitated with water. It is uncertain whether the acid effects a separation or induces a further reaction. The original crude precipitate seems to have a constant composition. R. V. S.

Vinyl*cyclo*propane and its Derivatives. NICOLAI J. DEMJANOV and M. DOJARENKO (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 176—184). —By various methods Gustavson (A., 1896, i, 669) obtained from vinyltrimethylene an alcohol, b. p. 115—118°. This alcohol is of tertiary character, and from the value of its optical exaltation and from the fact that its boiling point exceeds that of dimethylethyl-carbinol by 15°, which is also the difference between the boiling points of β-methylbutyl alcohol and *cyclo*butylcarbinol, the authors conclude that it is probably 1-methyl*cyclo*butan-1-ol,

$$CH_2{<}^{CH_2}_{CH_2}{>}CMe·OH,$$
and not 1-ethyl*cyclo*propan-1-ol.

The alcohol is converted by the action of hydriodic acid, first into the iodide, C_5H_9I, b. p. 50°/22 mm., 53°/30 mm., D_4^{18} 1·603, and

subsequently into the iodide, $C_5H_{10}I_2$. Reduction of the iodide C_5H_9I, by means of zinc dust and acetic acid yields (1) *ethyl*cyclo-

propane, $\begin{matrix}CH_2\\CH_2\end{matrix}\!\!>\!CHEt$, b. p. 34—35°/753 mm., D_0^0 0·6973, D_4^0 0·6971,

D_4^{17} 0·6805, n_D^{17} 1·3814, which is also obtained on reducing vinyl*cyclo*-propane by means of hydrogen in presence of platinum black, and (2) an ester, $C_7H_{14}O_2$, of the original alcohol and acetic acid.

<div align="right">T. H. P.</div>

Terpenes and Ethereal Oils. CXIV. Alicyclic Unsaturated Hydrocarbons. OTTO WALLACH (*Annalen*, 1913, 396, 264—284).— 4-Methyl*cyclo*hexan-1-one and magnesium methyl iodide yield by the usual method 1 : 4-dimethyl*cyclo*hexan-1-ol, which is converted by boiling dilute sulphuric acid into 1 : 4-dimethyl-Δ^1-*cyclo*hexene, b. p. 127—128°, $D^{19·5}$ 0·8020, n_D 1·4459. By oxidation with 1% potassium permanganate at 0°, the latter is converted into 1 : 4-*dimethyl*cyclo-*hexane*-1 : 2-*diol*, m. p. 77°, which yields 1 : 4-dimethyl*cyclo*hexan-2-one by treatment with dilute sulphuric acid.   1 : 4-Dimethyl-Δ^1-*cyclo*hexene forms a *nitrosochloride*, m. p. 83—84°, which is easily volatile with

steam, forms a *nitrolpiperidide*, $C_5NH_{10}\cdot CMe\!<\!\begin{matrix}C(:NOH)\cdot CH_2\\CH_2\!-\!\!-\!\!-\!CH_2\end{matrix}\!\!>\!CHMe$,

m. p. 169—170°, and is converted into 1 : 4-dimethyl-Δ^6-*cyclo*hexen-2-oneoxime by loss of hydrogen chloride.

i-1 : 3-Dimethyl*cyclo*hexan-3-ol is converted by boiling dilute sulphuric acid into 1 : 3-*dimethyl*-Δ^3-*cyclohexene*, b. p. 127·5—128·5°, D^{21} 0·8025, n_D^m 1·4466, which forms a *nitrosochloride* (the *nitrolpiperidide* has m. p. 130—131°) extremely slowly, and is oxidised to 1 : 3-dimethyl-*cyclo*hexane-3 : 4-diol by 1% potassium permanganate.

By careful fractional distillation with an efficient column, it can be shown that the liquid obtained by the auto-condensation of methyl-heptenone in the presence of zinc chloride or phosphoric oxide, and hitherto regarded as pure dihydro-*m*-xylene, contains 1 : 3-dimethyl-Δ^3-*cyclo*hexene. Also when methylheptenone is treated with 75% sulphuric acid, the product is shown to be a mixture of 1 : 3-dimethyl-Δ^3-*cyclo*hexene and *m*-xylene.

1 : 2-Dimethyl*cyclo*hexan-1-ol and boiling dilute sulphuric acid yield 1 : 2-dimethyl-Δ^1-*cyclo*hexene, b. p. 135—137° (Sabatier gives 132°), D^{20} 0·824, n_D^{20} 1·4587, which forms a *nitrosochloride*, m. p. 58—60°, colourless when solid, blue when liquid, from which an oxime cannot be obtained. The unsaturated hydrocarbon forms a *dibromide*, m. p. 154—156°, and a *glycol*, m. p. about 38—39°, by oxidation.

[With L. AUGSPURGER.]—By warming with dilute sulphuric acid, 4-methyl-1-ethyl*cyclo*hexan-1-ol yields chiefly 4-*methyl*-1-*ethyl*-Δ^1-cyclo-*hexene*, b. p. 153—154°, D^{22} 0·8145, n_D 1·4514, which forms a *nitroso-chloride* consisting of two stereoisomeric modifications, one having m. p. 103—104° and being sparingly soluble in acetone or petroleum, the other having m. p. 98—99° and being easily soluble. Both modifications yield the same *nitrolpiperidide*, m. p. 134°, and by loss of hydrogen chloride the same *oxime*, m. p. 59—60°. By oxidation with dilute potassium permanganate, 4-methyl-1-ethyl-Δ^1-*cyclo*hexene is

converted into 4-*methyl*-1-*ethylcyclohexane*-1 : 2-*diol*, m. p. 76—77', the constitution of which is proved by its conversion into 4-methyl-1-ethyl*cyclo*hexan-2-one.

[With HANS SCHLUBACH.]—1 : 3 : 5-*Trimethylcyclohexan*-1-*ol*, b. p. 181°, prepared from 3 : 5-dimethyl*cyclo*hexan-1-one and an excess of magnesium methyl iodide, is converted by boiling 50% sulphuric acid into 1 : 3 : 5-*trimethyl*-Δ^1-*cyclohexene*, b. p. 142·5—143·5°, D^{21} 0·7965, n_D^{21} 1·4447, which forms a *nitrosochloride*, m. p. 134° (*nitrolpiperidide*, m. p. 122—123°), and is oxidised to 1 : 3 : 5-*trimethylcyclohexane*-1 : 2-*diol*, m. p. 104°, by cold dilute potassium permanganate.   C. S.

Preparation of Partly Hydrogenised Cyclic Hydrocarbons. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 255538. Compare this vol., i, 349).—When dichloro*cyclo*hexane is heated at 350—450° and 15—20 mm. in the presence of potassium hydroxide, it gives rise to *cyclo*hexadiene, whilst 1 : 2-dibromo*cyclo*hexane furnishes $\Delta^{1.3}$-*cyclo*-hexadiene and chloro*cyclo*pentane yields *cyclo*pentene.   F. M. G. M.

Derivatives of Phenylacetylene, Methoxyphenylacetylene, and Allied Compounds. FRANZ KUNCKELL [with KURT ERAS, EMIL MULLER, and ALFRED HILDEBRANDT] (*Ber. Deut. Pharm. Ges.*, 1913, **23**, 188—227).—A recapitulation and extension of previous work on the preparation of derivatives of phenylacetylene from aryl chloro-methyl ketones (A., 1897, i, 282, 522 ; 1901, i, 75, 552, 638 ; 1903, i, 413).

p-Tolylacetylene combines with bromine to form a *dibromide*, a pale yellow oil, b. p. 139—143°/13 mm., D^{17} 1·669, and a yellow, viscid, oily *tetrabromide* ; with ammoniacal silver nitrate it yields a white, gelatinous *silver* salt, which forms an explosive grey powder when dry. The *copper* salt is light yellow, and is oxidised by aqueous potassium ferricyanide in the presence of potassium hydroxide to *di-p-tolylbuta-di-inene*, $C_7H_7\cdot C\vdots C\cdot C\vdots C\cdot C_7H_7$. This crystallises in white needles, m. p. 183°, and yields a *dibromide*, m. p. 148°, *tetrabromide*, m. p. 163°, and an *octabromide*, m. p. 156—157°.

p-Ethylphenylacetylene gives a yellow oily *dibromide*, b. p. 168—172°/20 mm., D^{18} 1·598, a *tetrabromide*, and greenish-grey *silver* salt ; the *copper* salt forms a light yellow powder, and is oxidised by alcoholic potassium ferricyanide to *di-p-ethylphenylbutadi-inene*, white needles, m. p. 72°.

αβ-Dichloro-2-bromo-5-methoxystyrene, $OMe\cdot C_6H_3Br\cdot CCl\vdots CHCl$, pre-pared from 2-bromo-5-methoxyphenyl chloromethyl ketone and phosphorus pentachloride, forms a yellowish-brown oil, b. p. 210—215°/25 mm., D^{18} 1·3610. When heated with phosphorus pentachloride on the water-bath, 3 : 4-dichloroacetyl-1-methoxybenzene gives rise to 1-*methoxy*-3 : 4-*bis-αβ-dichlorovinylbenzene*, $OMe\cdot C_6H_3(CCl\vdots CHCl)_2$, a pale yellow liquid, b. p. 160—170°/17 mm., D^{21} 1·461 ; if the reaction is carried out at a higher temperature, 2 : 5-*dichloro*-1-*methoxy*-3 : 4-*bis-αβ-dichlorovinylbenzene*, $OMe\cdot C_6HCl_2(CCl\vdots CHCl)_2$, a yellow oil, b. p. in vacuum 170—180°, D^{19} 1·570, is produced.

$\alpha\beta$ 2 : 5-*Tetrachloro*-4-*methoxystyrene*, OMe·C$_6$H$_2$Cl$_2$·CCl:CHCl, prepared by boiling *p*-methoxyphenyl chloromethyl ketone with excess of phosphoius pentachloride, is a yellow liquid of aromatic odour, b. p. 165—175°/18 mm., D^{17} 1·44; the prolonged action of phosphorus pentachloride gives rise to $\alpha\beta$ 2 : 3 : 5-*pentachloro*-4-*methoxystyrene*, a yellow oil which has b. p. 180—190°/20 mm., D^{18} 1·6100, and solidifies when kept.

$\alpha\beta$-*Dichloro*-p-*ethoxystyrene*, prepared from *p*-ethoxyphenyl chloromethyl ketone, is a brownish-yellow liquid of disagreeable odour, b. p. 170—180°/26 mm., D^{20} 1·243.

5-Methoxy-*o*-tolyl chloromethyl ketone gives rise to $\alpha\beta$-*dichloro*-5-*methoxy*-2-*methylstyrene*, OMe·C$_6$H$_2$Me·CCl:CHCl, a pale yellow oil, b. p. 160°/20 mm., D^{18} 1·2520; *chloro*-5-*methoxy*-o-*tolylacetylene* has b. p. 145—150°/15 mm., D^{18} 1·166. 5-*Methoxy*-o-*tolylacetylene* is a pale yellow liquid of ethereal odour, b. p. 110—120°/18 mm., D^{17} 1·011.

2 : 4-*Dimethoxyphenyl chloromethyl ketone*, prepared from resorcinol dimethyl ether and chloroacetyl chloride, crystallises in yellow leaflets, m. p. 104°, and yields with phosphorus pentachloride, $\alpha\beta$-*dichloro*-2 : 4-*dimethoxystyrene*, a reddish-yellow liquid which has a sweet odour and becomes crystalline when kept, b. p. 160—165°/18 mm.

Resorcinol diethyl ether and chloroacetyl chloride yield 4 : 4(?)-*dichloroacetyl*-1 : 3-*diethoxybenzene*, C$_6$H$_2$(OEt)$_2$(CO·CH$_2$Cl)$_2$, small, yellow needles, m. p. 106°.

Di-p-*chloroacetyldiphenyl ether*, O(C$_6$H$_4$·CO·CH$_2$Cl)$_2$, prepared from diphenyl ether and chloroacetyl chloride, forms greenish granules, m. p. 111°, and gives rise to *di*-p-$\alpha\beta$-*dichlorovinyldiphenyl ether*, O(C$_6$H$_4$·CCl:CHCl)$_2$, a viscid liquid having a green shimmer, b. p. 225°/20 mm.

2 : 6-Dichloroacetyl mesitylene, from chloroacetyl chloride and mesitylene, forms large, lustrous crystals, m. p. 134—135° (compare Meyer, A., 1897, i, 55), and yields 1 : 3 : 5-*trimethyl*-2 : 6-*bis*-$\alpha\beta$-*dichlorovinylbenzene*, C$_6$HMe$_3$(CCl:CHCl)$_2$, a colourless oil, b. p. 180—181°/12 mm., D^{18} 1·3106. When impure, the last-named substance gradually loses hydrogen chloride on exposure to air, yielding a white *substance*, m. p. 95°.

2 : 4 : 6-*Triethylphenyl chloromethyl ketone*, prepared from 2 : 4 : 6-triethylbenzene, is a strongly refractive liquid, b. p. 207—215°/20 mm., and yields $\alpha\beta$-*dichloro*-2 : 4 : 6-*triethylstyrene*, which forms a golden-yellow oil of aromatic odour, b. p. 175°/18 mm., D^{18} 1·1447; 2 : 4 : 6-*triethylphenylchloroacetylene*, a yellow oil, b. p. 155°/18 mm., D^{18} 1·0236; 2 : 4 : 6-*triethylphenylacetylene*, a colourless liquid, b. p. 124—126°/14—16 mm., D^{21} 0·9004, which forms a yellow, amorphous *copper* salt.

2 : 6-*Dichloroacetyl*-1 : 3 : 5-*triethylbenzene*, C$_6$HEt$_3$(CO·CH$_2$Cl)$_2$, crystallises in transparent, hexagonal plates, m. p. 71—72°, and gives rise to 1 : 3 : 5-*triethyl*-2 : 6-*di*-$\alpha\beta$-*dichlorovinylbenzene*, C$_6$HEt$_3$(CCl:CHCl)$_2$, a golden-yellow oil, b. p. 210—215°/17—18 mm., D^{18} 1·245.

2 : 4-*Di*-*chloroacetyl*-6-*acetyl*-1 : 3 : 5-*triethylbenzene*,

$$\text{COMe·C}_6\text{Et}_3(\text{CO·CH}_2\text{Cl})_2,$$

from 2 : 4 : 6-triethylphenyl methyl ketone and chloroacetyl chloride, crystallises in stout, transparent needles, m. p. 72°.   F. B.

Preparation of Sulphonic Acids of the Benzene and Naphthalene Series. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 255724. Compare Friedländer and Lucht, A., 1894, i, 138). —When an electric current is passed through an alkaline solution of an aniline-, naphthylamine- or naphthol-polysulphonic acid in the presence of sodium amalgam a sulphonic group is eliminated.

The reduction of the following compounds is described : aniline-3 : 6-disulphonic acid to aniline-3-sulphonic acid ; α-naphthylamine-4 : 8-disulphonic acid to α-naphthylamine-4-sulphonic acid ; β-naphthylamine-4 : 8-disulphonic acid to the corresponding -8-sulphonic acid ; β-naphthylamine-5 : 7-disulphonic acid to β-naphthylamine-7-sulphonic acid ; α-naphthylamine- 3 : 5 : 7-trisulphonic acid to α-naphthylamine-3 : 7-disulphonic acid ; α-naphthylamine-2 : 4 : 6-trisulphonic acid to α-naphthylamine-2 : 4-disulphonic acid ; α-naphthylamine-2 : 5 : 7-trisulphonic acid to α-naphthylamine-2 : 7-disulphonic acid ; α-naphthol-3 : 8-disulphonic acid to α-naphthol-3-sulphonic acid ; α-naphthol-2 : 4 : 8-trisulphonic acid to α-naphthol-2 : 4-disulphonic acid, and β-naphthol-3 : 6 : 8-trisulphonic acid to β-naphthol-3 : 6-disulphonic acid.

F. M. G. M.

Δ^1-Dihydronaphthalene. FRITZ STRAUS (*Ber.*, 1913, 46, 1051—1055).—By the exhaustive methylation of tetrahydro-β-naphthylamine, Willstätter and King (this vol., i, 353) have obtained a dihydronaphthalene which they consider to be identical with the Δ^2-dihydronaphthalene, described by Bamberger (A., 1896, i, 99).

The author points out, however, that the properties of Willstätter and King's dihydro-compound show such complete agreement with those of the Δ^1-dihydronaphthalene (this vol., i, 256) that there can be no doubt as to the identity of the two hydrocarbons.

Δ^2-Dihydronaphthalene forms a dibromide differing very little in m. p. from that of the Δ^1-isomeride. The removal of bromine by means of zinc in alcoholic solution yields in each case the original hydrocarbon. The statement of Willstätter and King that their dihydronaphthalene can be obtained by the removal of bromine from the dibromide of Bamberger's Δ^2 dihydro-compound is, therefore, erroneous.

F. B.

Halogen Compounds of Anthracene. KURT H. MEYER and KARL ZAHN (*Annalen*, 1913, 396, 166—180).—The halogen additive compounds of anthracene are derivatives of 1 : 2 : 3 : 4-tetrahydroanthracene. Attempts to replace the halogen atoms by hydroxyl, amino-, and other groups have been unsuccessful, but a new case of isomerism has been observed.

Graebe and Liebermann have shown that the action of bromine vapour on anthracene yields 9 : 10-dibromoanthracene tetrabromide. This yields 1 : 3 : 9 : 10-tetrabromoanthracene by treatment with alcoholic potassium hydroxide, 2 : 9 : 10-tribromoanthracene by heating, and 9 : 10-dibromoanthracene by reduction with zinc and acetic acid.

By treating anthracene moistened with chloroform with bromine (4 mols.) in chloroform, a *substance*, $C_{14}H_9Br_9$, m. p. 134—135° (decomp.), colourless needles, is obtained, which reacts like the older isomeride towards alcoholic potassium hydroxide, heating, and reducing agents. The two isomerides, therefore, are structurally alike. It is suggested that the two are stereoisomeric, the new compound, which is called a-9 : 10-*dibromoanthracene tetrabromide*, having the four homonuclear bromine atoms in *cis*-positions, whilst in the older (β-) compound they are alternately *cis* and *trans*. These configurations are in harmony with a property which is characteristic of the a-, but not of the β-isomeride. a-9 : 10 Dibromoanthracene tetrabromide in boiling benzene is decomposed into bromine and 9:10-dibromoanthracene by exposure to sunlight or to the light of a mercury lamp; the change is not reversible in boiling benzene in darkness.

a-9:10-*Dichloroanthracene tetrabromide*, $C_{14}H_8Cl_2Br_4$, m. p. 141—142° (decomp.), colourless, hexagonal prisms, prepared from dichloroanthracene and bromine (2 mols.) in chloroform, exhibits a similar photochemical decomposition in benzene, whilst the long-known β-isomeride does not.

The 9:10-dichloroanthracene tetrachloride obtained by Hammerschlag by passing chlorine into a benzene solution of anthracene is the β-isomeride, since it is photochemically inactive and does not liberate iodine from potassium iodide. The a-isomeride has not been obtained. The β-isomeride yields 1 : 3 : 9 : 10-tetrachloroanthracene (the constitution of which is proved by its conversion into 1 : 3-dichloroanthraquinone) by treatment with alcoholic potassium hydroxide, 2 : 3 : 9 : 10-*tetrachloroanthracene*, m. p. 240—241°, yellow needles (yielding 2 : 3-dichloroanthraquinone by oxidation), by heating above its m. p., and 9 : 10-dichloroanthracene by reduction with zinc and acetic acid.

9 : 9 : 10 : 10-Tetrachloroanthracene, m. p. 170° (Schwarzer gives 149—150°), obtained together with 9 : 10-dichloroanthracene tetrachloride by passing chlorine into a chloroform solution of anthracene at 0°, yields the *dianil*, $NPh:C{<}^{C_6H_4}_{C_6H_4}{>}C:NPh$, m. p. 201—202°, golden-yellow leaflets, with aniline in boiling alcohol, and the *tetramethylacetal*, $C(OMe)_2{<}^{C_6H_4}_{C_6H_4}{>}C(OMe)_2$, m. p. 161—162°, colourless crystals, with boiling methyl alcohol and sodium carbonate.

O. S.

Preparation of o-Substituted Derivatives of Acetoacetanilide and Their Homologues.

FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 256621).—3-*Chloroacetoaceto-o-toluidide*, colourless needles, m. p. 120°, is obtained in 66% yield when a solution of ethyl acetoacetate in chlorobenzene is added to a hot solution of 3-chloro-o-toluidine in the same solvent.

o-*Chloroacetoacetanilide* is prepared in 75% yield in a similar manner from o-chloroaniline.

Acetoaceto-o-anisidide, a colourless, crystalline powder, has m. p. 84°,

whilst the analogous *compounds* from 3-amino-*p*-tolyl ethyl ether and from *phenyl* o-*aminophenyl ether* have m. p. 80° and 61° respectively.

F. M. G. M.

The Manufacture of Tetranitromethylaniline. F. LANGENSCHEIDT (*Zeitsch. ges. Schiess-Sprengstoffwesen*, 1912, **7**, 445—447).—2 : 4 : 6-N-*Tetranitromethylaniline* ("Tetril") (annexed formula), m. p. 129—130°, is obtained in 87% yield when pure methyl- or dimethyl-aniline is dissolved in 10 parts of concentrated sulphuric acid (pure and free from lead), thoroughly cooled, and slowly added to 4·3 parts of nitric acid (47° Bé') at 40°, 44° being the utmost limit to which the temperature may rise in the early stages of the operation; later, when the violence of the action decreases, it is allowed to rise to, and maintained at, about 53—55°, and after about eleven hours the nitration is completed. The product is purified by crystallisation from benzene.
F. M. G. M.

[**Preparation of 4-Chloro-2 : 6-diaminophenol.**] FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 256794).—4-*Chloro*-2 : 6-*diaminophenol*, obtained by the reduction of 4-chloro-2 : 6-dinitrophenol, crystallises from hot water in needles, has m. p. 88—89°, and furnishes crystalline *salts*.

3 : 5-*Diamino*-p-*cresol*, m. p. 146°, is prepared by the reduction of the corresponding 3 : 5-dinitro-*p*-cresol.

F. M. G. M.

Preparation of Dialkylaminoformic Esters. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 255942).—When halogen formic esters are treated with trialkylamines the following reaction takes place : $ClCO_2R + NMe_3 = NMe_3Cl \cdot CO_2R$, and the compounds so obtained when heated give rise to dialkylaminoformic esters of the general formula : $NMe_3Cl \cdot CO_2R = NMe_2 \cdot CO_2R + MeCl$ (R may be alkyl, aryl, or alkylaryl).

Phenyl dimethylaminoformate, $NMe_2 \cdot CO_2Ph$, colourless needles, m. p. 44—45°, b. p. 134—135°/16 mm., is obtained in quantitative yield when a cooled benzene solution of trimethylamine is slowly treated with phenyl chloro-formate; the intermediate *compound*, $NMe_3Cl \cdot CO_2Ph$, separates as a colourless, crystalline precipitate, and, on subsequently boiling, the reaction mixture is slowly converted into the foregoing ester.

Tolyl dimethylaminoformate, $NMe_2 \cdot CO_2 \cdot C_6H_4Me$, a viscid, colourless oil, b. p. 145—195°/15 mm., consisting of a mixture of the ortho-, meta-, and para-isomerides, is prepared in a similar manner from the mixture of *tolyl chloroformates*, b. p. 85—105°/18 mm., obtained by the action of carbonyl chloride on a freshly distilled benzene solution of crude cresol (b. p. 190—206°) in the presence of dimethylaniline.

β-Naphthyl chloroformate, colourless prisms, m. p. 57° (prepared from carbonyl chloride and β-naphthol), when treated with trimethylamine furnishes the *compound*, $NMe_3Cl \cdot CO_2 \cdot C_{10}H_7$, as a colourless, crystalline precipitate, and on boiling is converted into *β-naphthyl dimethylaminoformate*, $NMe_2 \cdot CO_2 \cdot C_{10}H_7$, colourless crystals, m. p. 92°.

iso*Amyl dimethylaminoformate*, $Me_2N \cdot CO_2 \cdot C_5H_{11}$, a colourless oil, b. p. 194—197°, and *phenyl diethylaminoformate*, $NEt_2 \cdot CO_2Ph$, a colourless oil, b. p. 142—146°/13 mm , are prepared in a similar manner.

Preparation of Aromatic Selenocyano-compounds. FARB-WERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 255982).—An account of the preparation of compounds previously described by Bauer (this vol., i, 263); the m. p. of *o*-nitrophenyl selenocyanate is given as 144—145° (*loc. cit.*, 142°).   F. M. G. M.

Iron Compounds of Phenols. IV. RUDOLF F. WEINLAND and KARL BINDER (*Ber.*, 1913, **46**, 874—885).—The dark blue substance obtainable from catechol and ferric acetate, which dissolves in water to a green solution, was provisionally regarded as having the structure $Fe_3(C_6H_4O_2)_4 \cdot OH, 7H_2O$ (A., 1912, i, 445), but it is now shown to yield acetic acid when warmed, and to contain actually one atomic weight of iron to a molecular weight of acetic acid and of catechol; it is obtained when two molecular proportions of ferric acetate are mixed with 1—2 of catechol in aqueous solution. If, however, four times the above quantity of catechol is used the violet acid, $H\begin{bmatrix} Fe(C_6H_4O_2)_2 \\ H_2O \end{bmatrix}, H_2O$ (*loc. cit.*), is obtained. It is therefore a probable conclusion that the substance which yields a green solution is a complex salt containing as components the above violet acid and the hexa-acetotriferric base (Weinland and Gussmann, A., 1910, i, 457), the constitution accordingly being :

$$[Fe_3(OAc)_6][Fe(C_6H_4O_2)_2]_3, 12H_2O.$$
The view is confirmed by the production of a green colour on the addition of the red solution of ferric acetate to a solution of an alkali salt of the above violet acid, or on the addition of a little catechol to ferric acetate solution. It is suggested that the green coloration produced by ferric chloride solution with catechol may be due to the formation of some analogous complex salt. The green colour of the solutions of the above complex salt is not due to the mere superposition of the colours of the acid and metallic radicles, but the possibility is not excluded that some decomposition may occur during the process of solution with formation of still unknown complexes.

The preparation of the violet acid can be effected without the addition of sodium acetate (compare A , 1912, i, 445), provided that sufficient catechol is added to decompose all the ferric acetate.

As ferric chloride is soluble in certain organic solvents, the reaction of this substance with catechol was examined in other solvents than water. In ethereal solution the reaction product was a crystalline, blackish-brown *substance*, $Fe(O \cdot C_6H_4 \cdot OH)Cl_2, Et_2O$ (compare A., 1912, i, 850), which may possibly be an oxonium salt of ether with the acidic portion of the substance; it is very sensitive to moisture, and soon becomes decomposed in the air; in alcohol it gives a blue solution. The reaction in acetophenone solution yields a product which when precipitated by pyridine forms bluish-black, microscopic leaflets of a

substance which may be regarded as a pyridine salt of the acid present in the last substance, that is, $(C_5H_5N)_4.[HFe(C_6H_4O_2)Cl_2]_4$. In pyridine solution a bluish-black, crystalline powder consisting of microscopic leaflets is obtained; the structure of this substance may be that of a salt of the red acid, $H_3[Fe^{III}(C_6H_4O_2)_3]$ (A., 1912, i, 445), with complex bases, and the formula $Fe(C_6H_4O_2)_3 < \genfrac{[}{]}{0pt}{}{Fe(C_5H_5N)_4Cl.H_2O}{Fe(C_5H_5N)_3Cl_2,H_2O}$ is suggested.

The potassium salt of the violet acid retains its molecule of water in a vacuum over sulphuric acid for six months, and the potassium salt of the red acid holds its $2H_2O$ equally tenaciously; the sodium salt of the latter acid, however, yields 8 of its 9 H_2O under similar treatment.

D. F. T.

Some Additive Products of Styphnic Acid. CLAUDIO AGOSTINELLI (*Gazzetta*, 1913, **43**, i, 124—128).—The additive compound of 3:5-*dimethylpyrazole* and styphnic acid,

$$C_5H_8N_2,C_6H_3O_8N_3,$$
crystallises in golden-yellow scales, m. p. 203—204°. The compound from *antipyrine*, $C_{11}H_{12}ON,C_6H_3O_8N_3$, crystallises in canary-yellow laminæ, m. p. 204°. The compound from *pyramidone*,

$$C_{13}H_{17}ON_3,C_6H_3O_8N_3,$$
forms thin, yellow needles, m. p. 191°. The compound from *camphorphenylhydrazone*, $C_{10}H_{16}{:}N{\cdot}NHPh,C_6H_3O_8N_3$, crystallises in green, woolly needles, m. p. 150—151°. The compound from *acetonephenylhydrazone*, $C_9H_6{:}N{\cdot}NHPh,C_6H_3O_8N_3$, crystallises in yellowish-green scales, m. p. 104—106°. The compound from *cinnamaldehydephenylhydrazone*, $C_{15}H_{14}N_2,(C_6H_3O_8N_3)_2$, forms minute, pale green needles, m.p. 137—138°. The compound from *benzylidene-aniline*, $C_{13}H_{11}N,C_6H_3O_8N_3$, crystallises in pale yellow scales, m. p. 193°. The compound from *cinnamylideneaniline*,

$$C_{15}H_{13}N,C_6H_3O_8N_3,$$
crystallises in bright red laminæ, m. p. 178°. The compound from *benzylideneazine*, $C_{14}H_{12}N_2,C_6H_3O_8N_3$, forms yellow needles, m. p. 152°. The compound from *cinnamylideneazine*, $C_{18}H_{16}N_2,C_6H_3O_8N_3$, crystallises in orange-yellow needles, m. p. 176°.

R. V. S.

Preparation of 2:3-Dihydroxytoluene. SACCHARIN-FABRIK AKTIENGESELLSCHAFT VORM. FAHLBERG, LIST & CO. (D.R.-P. 256345).— 2:3-Dihydroxytoluene, m. p. 68°, b. p. 241° or 112°/3 mm., as obtained by Limpach (A., 1892, 447) had m. p. 47°, and the following method of preparation is now described. *o*-Cresol is sulphonated, and the *o*-cresol-5-sulphonic acid so obtained, chlorinated, when it yields 3-*chloro-o-cresol*-5-*sulphonic acid* (annexed formula); this when heated at 130° with dilute sulphuric acid gives rise to 3-*chloro-o-cresol*, m. p. 185°, or if fused for 8—10 hours at 160—170° with sodium hydroxide and again subsequently heated at 200° with water under pressure, it yields 2:3-dihydroxytoluene in glistening, colourless leaflets.
F. M. G. M.

Some New Polymerides of the Phenols with Propenylic Side-chains. ERNESTO PUXEDDU (*Gazzetta*, 1913, 43, i, 128—133).— The author has obtained new polymerides of *iso*safrole and anethole by methods based on the employment of an anhydrous ethereal solution of ferric chloride.

When an anhydrous ethereal solution of *iso*eugenol and ferric chloride is treated with dry hydrogen chloride for three hours, the di*iso*eugenol already known is produced.

If an absolute ethereal solution of *iso*safrole and ferric chloride is treated with dry hydrogen chloride for five days, a new *polymeride* of *iso*safrole is produced ; it crystallises in spherical nodules, m. p. 92°, and reacts with bromine with evolution of hydrogen bromide and formation of an oily product.

Anethole, when treated in a manner similar to that described in the two preceding cases, yields a new *polymeride*, which, however, is better prepared by simply mixing anhydrous ethereal solutions of anethole and ferric chloride ; the mixture deposits a white powder, which does not melt at 340°.   R. V. S.

Action of Nitrous Acid on Ethyl*iso*eugenol. ERNESTO PUXEDDU (*Gazzetta*, 1913, 43, i, 133—138. Compare A., 1912, i, 186).—The paper deals with the ethyl*iso*eugenol peroxide previously described (*loc. cit.*) with a view to showing its analogy to similar substances investigated by Angeli and others (A., 1893, i, 261, 263 ; 1894, i, 72 ; 1895, i, 35). When the peroxide is boiled with alcoholic potassium hydroxide for a few minutes, it is converted into a *substance*, $C_{12}H_{14}O_4N_2$, which crystallises in long, yellow, prismatic needles, which become red at 170°, m. p. 180° (decomp.).

Reduction of the peroxide with tin and hydrochloric acid yields a furazan derivative, $C_{12}H_{14}O_3N_2$, m. p. 116°. When the reduction is effected by zinc and acetic acid in certain conditions, *ethyliso*eugenol-*a*-dioxime, $C_{12}H_{16}O_4N_2$, is produced ; it forms lustrous scales, m. p. 150°. On heating at 150° for some hours, it yields the *β-dioxime*, which forms prismatic crystals, m. p. about 190°.   R. V. S.

Some Derivatives of Hydroxyquinol. IX. GUIDO BARGELLINI (*Gazzetta*, 1913, 43, i, 164—175. Compare Bargellini and Avrutin, A., 1911, i, 68).—The paper deals with the constitution of two sub-stances obtained by the action of zinc chloride on triacetylhydroxy-quinol, and described in the paper cited.

The red substance of m. p. 200—202° is 2 : 4 : 5-*trihydroxyaceto-phenone*, for it is formed by the saponification of the white substance of m. p. 165—166°, and it also results from the action of potassium persulphate on resacetophenone in alkaline solution (compare Bargellini and Aureli, A., 1911, i, 855). Benzoyl chloride yields 2 : 4 : 5-*tri-benzoyloxyacetophenone* with both substances ; it forms colourless needles, m. p. 131—133°. Acetyl chloride gives with both red and white compounds a substance of the empirical formula C_8H_2O, m. p. 110—111°, which is 2 : 4 : 5-*triacetoxyacetophenone*. Both red and white compounds yield diacetyl-β-methylæsculetin (Bargellini and Martegiani, A., 1912, i, 292) when heated with acetic anhydride and

sodium acetate ; the formation of another substance, which begins to decompose at 245°, was also observed.   The reactions above described, taken in conjunction with the results of the molecular weight determination and of the estimation of saponifiable acetic acid in the compound, show that the white substance is a *hydroxydiacetoxy-acetophenone*.

The reaction between zinc chloride and triacetylhydroxyquinol thus results in a migration of one of the acetyl groups to a carbon atom of the nucleus.   Other similar reactions are known.   R. V. S.

Behaviour of Individual Organo-magnesium Compounds Towards Aromatic Ethers. VLADIMIR V. TSCHELINCEV and B. V. PAVLOV (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 289—300. Compare A., 1906, ii, 334, 335 ; A., 1907, i, 499 ; A., 1908, i, 254 ; Stadnikov, and also Stadnikov and Kuzmina-Aron, A., 1912, i, 971). —The authors have investigated the products formed and the thermal changes involved in the action of magnesium propyl iodide on (1) benzyl ethyl ether ; (2) diphenylmethyl ethyl ether, and (3) triphenylmethyl ethyl ether.   The products are (1) phenylbutane, *s*-diphenylethane, benzene, and ethyl alcohol ; (2) diphenylbutane and *s*-tetraphenylethane, and (3) triphenylmethane and ethyl alcohol.   The heat effects observed also indicate, not merely a combination of the ether with the organo-magnesium compound, but a more profound interaction.

These results show that when ethers of the aromatic series, which are less stable than the corresponding ones of the aliphatic series, react with organo-magnesium compounds, they are partly divided at the junction of the aromatic radicle with the oxygen of the alkoxy-group.   This division leads to the formation of aromatic hydrocarbons of two types : (1) CH_2PhPr, $CHPh_2Pr$, CPh_3Pr, and (2)

$$CH_2Ph\cdot CH_2Ph,$$
$CHPh_2\cdot CHPh_2$, $CPh_3\cdot CPh_3$.   These hydrocarbons are produced in accordance with the scheme advanced by Erlenmeyer, jun.: (1) $R\cdot OEt + 1Mg\cdot Pr = R\cdot Pr + OEt\cdot MgI$, and (2) $2R\cdot OEt + 2IMg\cdot Pr = R\cdot R + Pr\cdot Pr + 2OEt\cdot MgI$.

Since these hydrocarbons represent the actual products of the interaction of organo-magnesium compounds and ethers, and are not formed only after the action of water on these products, any attempt to draw conclusions concerning the structure of the ethereal complexes of organo-magnesium compounds on the basis of experimental results of this kind is pure speculation.

Further, no certain conclusions can be deduced from consideration of the products obtained by decomposition of the complexes by means of carbon dioxide (compare Stadnikov and Kuzmina-Aron, A., 1912, i, 971), since such decomposition is not quantitative, especially when molecular proportions of the ether and organo-magnesium compound are taken, and at the same time there is no exclusion of the possibility of formation from undecomposed magnesium alkyl iodide of the corresponding fatty acid, and hence of, for example, triphenylacetic acid.

In deciding between the two structures: R_2:$O(MgR)I$ and
$$R_2\text{:}O(MgI)R,$$
it must be borne in mind that ethereal complexes of this type are
obtained, not only with such compounds as MgRI, but also with
magnesium iodide, and in the latter case the only possible structure is
R_2:OI·Mg·OI:R_2.   T. H. P.
Reduction by means of Organo-magnesium Compounds.
ALEXANDER I. GORSKI (*J. Russ. Phys. Chem. Soc.*, 1913, **45**, 163—166).
—The author has previously (A., 1912, i, 622) expressed the opinion
that the formation of triphenylmethane by the interaction of triphenyl-
methyl ethyl ether, propyl iodide, and magnesium in an indifferent
solvent is due to hydrolytic decomposition of the ether into triphenyl-
methyl iodide and reduction of the latter to the corresponding
hydrocarbon. As alkyl iodides and magnesium, however, react in absence
of an ether or other catalyst, it may be that in the above case no
etherate of the type Pr·Mg·OEt is formed, but that these reactions
take place between the individual organo-magnesium compounds and
the ether.

In order to test the accuracy of this view, experiments were made
in which the triphenylmethyl ethyl ether was replaced by other
oxygenated compounds, such as ketones. The reaction between
β-benzopinacolin and magnesium propyl iodide in toluene solution
proceeds in the same direction as the reaction with triphenylcarbinol
in presence of ethyl ether, giving a compound apparently identical
with benzopinacolin alcohol. Similarly, benzophenone yields benz-
hydrol and other compounds. It is known that the action of organo-
zinc compounds on aldehydes and on ketones may, under certain
experimental conditions and with certain radicles in the organo-
metallic compounds, result in the reduction of the aldehydes to
primary, and of the ketones to secondary, alcohols ; hence the
reaction with β-benzopinacolin may be represented by the equation :
$$CPh_3 \cdot COPh + MgPrI = CPh_3 \cdot CHPh \cdot OMgI + C_3H_6.$$
That the reaction between nascent organo-magnesium compounds
and ketones is not generally limited to such a reduction is, however,
rendered evident by the fact that the secondary alcohol is not the sole
final product.

These considerations indicate the possibility that the reaction
between triphenylmethyl ethyl ether and magnesium propyl iodide
may be one of direct reduction, without intermediate formation of
iodide : $CPh_3 \cdot OEt + MgPrI = CHPh_3 + OEt \cdot MgI + C_3H_6$.   T. H. P.

Phenylethanolamines, Phenylnitroethanols, and their Hydr-
oxy-derivatives. KARL W. ROSENMUND (*Ber.*, 1913, **46**, 1034—1050.
Compare A., 1910, i, 106 ; 1911, i, 34).—An account of a preparation
of a number of β-hydroxy-β-arylethylamines, $OH \cdot CHR \cdot CH_2 \cdot NH_2$, by the
reduction of the corresponding nitro-alcohols, $OH \cdot CH \cdot CHR \cdot CH_2 \cdot NO_2$.
The latter compounds are obtained in good yield by decomposing the
sodium salts, produced by the condensation of aromatic aldehydes with
nitromethane in the presence of sodium methoxide, with acetic acid.
On treatment with mineral acids or when heated, the nitro-alcohols

lose water with the formation of the corresponding nitrostyrenes, R·CH:CH·NO₂. They dissolve in alkalis, yielding colourless solutions from which acetic acid liberates the nitro-alcohols unchanged, whilst mineral acids give rise to β-nitrostyrenes.

When dissolved in alkalis and the solutions acidified with acetic acid, the β-nitrostyrenes combine with water to form nitro-alcohols.

A similar addition of alcohol, resulting in the formation of nitro-ethers of the type OEt·CHR·CH₂·NO₂, may be effected by treating the nitrostyrenes with alcoholic alkali hydroxides and subsequently acidifying with acetic acid.

Although hydroxybenzaldehydes do not directly condense with nitromethane, the preparation of the corresponding nitrostyrenes and nitro-alcohols may be readily accomplished by the method illustrated in the following example: p-hydroxybenzaldehyde is converted into p-ethylcarbonatobenzaldehyde (I), CO₂Et·O·C₆H₄·CHO, which instantly reacts with nitromethane in the presence of alkali, yielding the salt CO₂Et·O·C₆H₄·CH(OH)·CH:NO·OK; on treatment with hydrochloric or acetic acid this yields the compounds (II)

$$CO_2Et·O·C_6H_4·CH:CH·NO_2$$
and (III) CO₂Et·O·C₆H₄·CH(OH)·CH₂·NO₂ respectively. If excess of alkali is employed and the reaction mixture allowed to remain for one to two minutes, the carbethoxy-group is removed and subsequent acidification yields (IV) OH·C₆H₄·CH:CH·NO₂ or (V)

$$OH·C_6H_4·CH(OH)·CH_2·NO_2,$$
accordingly as hydrochloric or acetic acid is employed.

β-*Nitro-a-phenylethyl alcohol*, OH·CHPh·CH₂·NO₂, prepared by condensing benzaldehyde with nitromethane in alcoholic solution by means of sodium methoxide below 8° and acidifying the aqueous solution of the resulting sodium salt with dilute acetic acid, is a yellow oil, b. p. 163—165°/15 mm. On treatment with sodium methoxide in methyl-alcoholic solution, β-nitrostyrene yields a colourless solution, from which the successive addition of acetic acid and water liberates β-*nitro-a-phenylethyl methyl ether*, OMe·CHPh·CH₂·NO₂, as a pale yellow oil, b. p. 140—141°/15 mm.

β-*Nitro-a-p-methoxyphenyl ethyl alcohol*, OMe·C₆H₄·CH(OH)·CH₂·NO₂, prepared by acidifying with acetic acid an aqueous solution of the *sodium* salt, obtained by the condensation of anisaldehyde and nitromethane with sodium methoxide, is a yellow oil, which partly decomposes on distillation or on treatment with mineral acids into β-nitro-p-methoxystyrene.
β-*Nitro-a-*p-*methoxyphenylethyl methyl ether*,
$$OMe·C_6H_4·CH(OMe)·CH_2·NO_2,$$
is a yellow oil.

p-Benzyloxybenzaldehyde condenses with nitromethane, yielding β-*nitro-*p-*benzyloxystyrene*, C₇H₇·O·C₆H₄·CH:CH·NO₂, m. p. 120°, from which β-*nitro-a-*p-*benzyloxyphenylethyl methyl ether*,
$$C_7H_7·O·C_6H_4·CH(OMe)·CH_2·NO_2,$$
m. p. 105—106°, is obtained in the usual manner.
p-*Benzoyloxybenzaldehyde*, prepared by the successive addition of the theoretical amount of potassium hydroxide and benzoyl chloride to an alcoholic solution of p-hydroxybenzaldehyde, yields with nitromethane

β-nitro-p-*benzoyloxystyrene*, which crystallises in slender, pale yellow needles, m. p. 153—155°. *β-Nitro-a-p-benzoyloxyphenylethyl alcohol* forms almost white, lustrous scales, m. p. 127—130°, and yields a white *sodium* salt. p-*Ethylcarbonatobenzaldehyde* (I), prepared from p-hydroxy-benzaldehyde and ethyl chloroformate in the presence of alkali, is a colourless oil, b. p. 170—172°/13 mm., and yields *β-nitro*-p-*ethylcarbonatostyrene* (II), crystallising in slender, pale yellow needles, m. p. 112—113°.

β-Nitro-a-p-ethylcarbonatophenylethyl alcohol (III) forms yellow needles, m. p. 91·5°. *β-Nitro*-p-*hydroxystyrene* (IV), prepared by hydrolysing its acyl derivatives with cold aqueous potassium hydroxide, crystallises in stout, long needles, m. p. 154—160° (decomp.). *β-Nitro-a*-p-*hydroxyphenylethyl alcohol* (V) is a yellow syrup.

4-*Benzoyloxy-3-methoxybenzaldehyde*, prepared by benzoylating vanillin by the pyridine method, has m. p. 75—76°, and condenses with nitro-methane, yielding *β-nitro-4-benzoyloxy-3-methoxystyrene*, which forms slender, pale yellow needles, m. p. 152—155°, and is hydrolysed by alcoholic potassium hydroxide to vanillylidenenitromethane (A., 1905, i, 65).

4-*Ethylcarbonato-3-methoxybenzaldehyde*, prepared from vanillin and ethyl chloroformate, has m. p. 71° and loses CO_2, at 135°, yielding 3-methoxy-4-ethoxybenzaldehyde; with nitromethane it yields *β-nitro-4-ethylcarbonato-3-methoxystyrene*, m. p. 125°, and *β-nitro-a-4-ethylcarbonato-3-methoxyphenylethyl alcohol*, which crystallises in stout needles, m. p. 84—86°.

3 : 4-*Dibenzoyloxybenzaldehyde*, prepared from protocatechualdehyde in a similar manner to that given for p-benzoyloxybenzaldehyde, separates from alcohol in rosettes of white needles, m. p. 96—97°, and gives rise to *β-nitro-3* : 4-*dibenzoyloxystyrene*,

$$C_6H_3(OBz)_2 \cdot CH:CH \cdot NO_2,$$
which forms slender, pale yellow needles, m. p. 143—144°, and is hydrolysed by alcoholic potassium hydroxide to *β-nitro-3* : 4-*dihydroxy-styrene*, crystallising in yellow needles or leaflets, m. p. 155—157°, with previous darkening at 145—148° (decomp. 160°).

3 : 4-*Diethylcarbonatobenzaldehyde*, obtained from ethyl chloroformate and protocatechualdehyde, is a colourless oil, b. p. 215—217°/13 mm., and yields with nitromethane, *β-nitro-3* : 4-*diethylcarbonatostyrene*, yellow needles, m. p. 72°.

Acidification of the products, resulting from the condensation of 3 : 4-diethylcarbonato- and 3 : 4-dibenzoyloxy-benzaldehyde with nitro-methane in the presence of sodium methoxide, with acetic acid yields *β-nitro-a-3* : 4-*diethylcarbonatophenylethyl alcohol* and *β-nitro-3* : 4-*dibenzoyloxyphenylethyl alcohol*, as yellow oils. If excess of sodium methoxide is used, *β-nitro-3* : 4-*dihydroxyphenylethyl alcohol* is formed. *Alkyl ethers* of the last-mentioned compound have also been prepared, but these resemble the previously-mentioned nitro-alcohols derived from 3 : 4-dihydroxybenzaldehyde in being too unstable to allow of their isolation in a state of purity. Their constitution was therefore established by reduction to the corresponding amino-alcohols and ethers.

β-Hydroxy-β-phenylethylamine is obtained by reducing *β-nitro-a-*

phenylethyl alcohol with sodium amalgam and acetic acid in aqueous alcoholic solution; it is accompanied by a substance of feeble basic properties, m. p. 217—218°.

β-Methoxy-β-phenylethylamine hydrochloride,

$$OMe \cdot CHPh \cdot CH_2 \cdot NH_2, HCl,$$

obtained by reduction of β-nitro-α-phenylethyl methyl ether in a similar manner, crystallises in white needles, m. p. 158—159°.

Successive treatment of β-nitro-*p*-methoxystyrene with alcoholic potassium hydroxide and acetic acid gives rise to *β-nitro-α-p-methoxyphenylethyl ethyl ether.*. On reduction this yields *β-ethoxy-β-p-methoxyphenylethylamine,* $OMe \cdot C_6H_4 \cdot CH(OEt) \cdot CH_2 \cdot NH_2$, as a syrup which slowly crystallises and yields a hydrochloride, m. p. 173—175° (decomp. 182°).

β-Methoxy-β-p-methoxyphenylethylamine, obtained from β-nitro-α-*p*-methoxyphenylethyl methyl ether, forms a *hydrochloride,* crystallising in white needles, m. p. 166—166·5° (decomp. 186—187°).

β-Hydroxy-β-p-methoxyphenylethylamine hydrochloride has m. p. 171—172°.

β-Nitro-β-3 : 4-dimethoxyphenylethyl methyl ether, obtained as a yellow oil by dissolving β-nitro-3 : 4-dimethoxystyrene (A., 1911, i, 34) in methyl-alcoholic sodium methoxide, is reduced by sodium amalgam and acetic acid to β-methoxy-β-3 : 4-dimethoxyphenylethylamine, identical with the arterenol trimethyl ether of Mannich and Neumann (A., 1910, i, 413).

The condensation of veratraldehyde and nitromethane with sodium methoxide yields the *sodium* salt of *β-nitro-α-3 : 4-dimethoxyphenylethyl alcohol,* which on decomposition with acetic acid and subsequent reduction is converted into *β-hydroxy-β-3 : 4-dimethoxyphenylethylamine,* $C_6H_3(OMe)_2 \cdot CH(OH) \cdot CH_2 \cdot NH_2$, the *hydrochloride* of which crystallises in leaflets, m. p. 163°.

β-Hydroxy-3 : 4-dihydroxyphenylethylamine is obtained in an impure condition by the reduction of β-nitro-α-3 : 4-dihydroxyphenylethyl alcohol; the *hydrochloride* gives an intense catechol reaction with ferric chloride.   F. B.

Action of Sulphuric Acid on Tetramethyldiaminobenzhydrol. The Pinacone of Michler's Ketone. S. FISCHL (*Monatsh.*, 1913, 34, 337—350).—The observation of Rosenstiehl (A., 1895, i, 541) and of Weil (A., 1894, i, 419; 1895, ii, 145), that tetramethyldiaminobenzhydrol is converted into hexamethyltriaminotriphenylmethane by warming with dilute sulphuric acid is confirmed, and it is further shown that by the action of sulphuric acid, Michler's ketone is formed, which then condenses with some of the unchanged hydrol producing a substance of the formula :

$$CH(C_6H_4 \cdot NMe_2)_2 \cdot C_6H_3(NMe_2) \cdot CO \cdot C_6H_4 \cdot NMe_2.$$
Tetramethyldiaminobenzhydrol, when dissolved in sulphuric acid and gently warmed, furnishes Michler's ketone (tetramethyldiaminobenzophenone), together with a *substance,* $C_{34}H_{40}ON_4$, m. p. 212—213°, crystallising from methyl alcohol in slender, silky needles, or from benzene on addition of light petroleum in short colourless prisms ; it is readily soluble in benzene, less so in acetone, and must have the

constitution given above, since it is also formed by the condensation of Michler's ketone with tetramethyldiaminobenzhydrol in presence of sulphuric acid.   It is unaffected by acids or alkalis, but on oxidation furnishes a greenish-blue dye.   The reactions of the substance indicate that the ·CO· group is in the ortho-position to the methane residue.

Tetramethyldiaminobenzophenone is not affected by zinc and acetic acid, but may be reduced electrolytically or by zinc with sulphuric or hydrochloric acid, giving the corresponding pinacone,

$$OH \cdot C(C_6H_4 \cdot NMe_2)_2 \cdot C(C_6H_4 \cdot NMe_2)_2 \cdot OH,$$
m. p. 195° (compare Escherich and Moest, A., 1903, i, 89).   This is somewhat soluble in benzene, but almost insoluble in alcohol; its solution in acetic acid is colourless in the cold, but becomes blue on warming.   It dissolves in sulphuric acid, forming a deep red solution, which on heating at 115—120° gives rise to the corresponding *pinacolin*,

$$C_{34}H_{40}ON_4,$$
m. p. 232—233°, which crystallises with one mol. of benzene in glandular masses of glancing prisms.   On heating with alcoholic potassium hydroxide, the pinacone is converted into a mixture of the ketone and the hydrol.   T. A. H.

1 : 1-Dimethylol*cyclo*butane.   NICOLAI D. ZELINSKI and M. N. UJEDINOV (*Ber.*, 1913, 46, 1093—1094).—A solution of ethyl tetramethylenedicarboxylate in absolute alcohol was added to sodium covered with dry ether, and, after the first vigorous action had subsided, the product was heated at 130—140° until the sodium was completely dissolved.   After addition of water, the alcohol was removed by distillation and the residue poured into water and saturated with potassium carbonate. The oil which separated was removed, united with a portion obtained by extracting the aqueous liquor with ether, and fractionated.   Thereby, cyclo*butylcarbinol*, $C_4H_7 \cdot CH_2 \cdot OH$, b. p. 142—144°/760 mm., was obtained, together with 1 : 1-*dimethylolcyclobutane*, $C_4H_6(CH_2 \cdot OH)_2$, a viscous, pale yellow oil, b. p. 145—147°/20 mm.   H. W.

The Iodohydrin of the Glycol Derived from Cinnamyl Methyl Ether.   HENRI BEAUFOUR (*Bull. Soc. chim.*, 1913, [iv], 13, 349—353.   Compare A., 1912, i, 621).—The iodohydrin obtained by treating cinnamyl methyl ether with iodine and mercuric oxide (*loc. cit.*) may have the formula $OH \cdot CHPh \cdot CHI \cdot CH_2 \cdot OMe$ or

$$CHPhI \cdot CH(OH) \cdot CH_2 \cdot OMe.$$

The results recorded in this and the next abstract support the first formula.

On treatment with powdered potassium hydroxide the iodohydrin (D$_{10}^{10}$ 1·500) furnishes the corresponding *oxide*, $CHPh \overset{O}{\underset{CH \cdot CH_2 \cdot OMe}{\diagdown}}$,

D$_0^0$ 1·0714, b. p. 127—128°/14 mm., a mobile, colourless liquid with a pungent odour; it does not combine with bromine, but reacts energetically with hydriodic acid, forming an iodo-derivative which probably has the second formula quoted above.

With dimethylamine the iodohydrin yields *ω-methoxymethylephedrine*,

OH·CHPh·CH(NMe$_2$)·CH$_2$·OMe, m. p. 76°, h. p. 152—153°/12 mm., which crystallises in colourless needles, and furnishes a *hydrochloride*, m. p. 170°, *hydriodide* m. p. 102—103°, *methiodide*, m. p. 160°, *picrate*, m. p. 152—153°, and with ethyl chloroacetate a *morpholone*, m. p. 168°. The *hydrochloride* of the *benzoyl* derivative, m. p. 118°, crystallises in spangles, has a bitter taste, and has a slow but distinct numbing action on the tongue. T. A. H.

Alkyliodohydrins Derived from Cinnamyl Methyl Ether. HENRI BEAUFOUR (*Bull. Soc. chim.*, 1913, [iv], 13, 354—358. Compare A., 1912, i, 621, and preceding abstract).—The methyl- and ethyl-iodohydrins, OR·CHPh·CHI·CH$_2$·OMe, already described differ from the simple iodohydrin (preceding abstract) in being more stable. The methyliodohydrin, D$_0^0$ 1·5070, b. p. 160—161°/15 mm., does not react with potassium hydroxide, except in alcohol, and then furnishes at 100°, the *ether*, OMe·CPh:CH·CH$_2$·OMe, D$_0^0$ 1·0483, b. p. 243°/760 mm., 128—129°/13 mm., a strongly-smelling liquid, which combines vigorously with bromine, reduces potassium permanganate solution, and when treated with steam in presence of sulphuric acid yields *phenyl vinyl ketone*, COPh·CH:CH$_2$, b. p. 110—115°/15 mm., which readily polymerises, and yields a *dibromide*, m. p. 56°, crystallising in colourless needles.

The methyliodohydrin reacts only feebly with dimethylamine at 120°, giving the *amine*, OMe·CHPh·CH(NMe$_2$)·CH$_2$·OMe, b. p. 132—133°/11 mm., whilst at higher temperatures, tarry products result.

The ethyliodohydrin (D$_0^0$ 1·4568) behaves like its lower homologue, and with potassium hydroxide in alcohol yields the ethylenic *ether*, OEt·CPh:CH·CH$_2$·OMe, D$_0^0$ 1·0428, b. p. 137—139°/15 mm., whilst with dimethylamine it is even less reactive. T. A. H.

Preparation of Aromatic Amino-alcohols. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 256750).—The previously described reduction of amino-ketones in the presence of colloidal metals of the platinum group (this vol., i, 361) is found to proceed equally satisfactorily if the metal is in a state of very fine division, and the preparation of 3 : 4-dihydroxyphenyl-α-propanolamine and of 3 : 4-dimethoxyphenyl-α-propanolamine in the presence of finely-divided palladous chloride are described. F. M. G. M.

1 - Methyl*cyclo*pentane - 1 - carboxylic Acid. ALEXEI E. TSCHITSCHIBABIN (*J. Russ. Phys. Chem. Soc.*, 1913, 45, 184—188).—*cyclo*Pentanone (compare Aschan, A., 1912, i, 536) was converted into 1-methyl*cyclo*pentan-1-ol (compare Zelinski and Nametkin, A., 1902, i, 672), this into 1-methyl-1-chloro*cyclo*pentane, and the latter, by the action of magnesium in ethereal solution and then of carbon dioxide, into 1 - *methylcyclopentane* - 1 - *carboxylic acid*, $\genfrac{}{}{0pt}{}{CH_2·CH_2}{CH_2·CH_2}$>CMe·CO$_2$H, which is an unpleasant smelling liquid, b. p. 219—219·5°, D$_4^{10}$ 1·0218, D$_4^0$ 1·0392. Its *silver* and *cadmium* salts were analysed. The *methyl* ester, C$_8$H$_{14}$O$_2$, b. p. 159·5°/721 mm., D$_4^{20}$ 0·9641, D$_4^0$ 0·9850, D$_4^{185}$ 0·9657, n_D^{185} 1·43727, and the *amide*, C$_7$H$_{13}$ON, m. p. 124—125° were prepared. T. H. P.

Dihydrocamphoceic Acid (Camphenilolic Acid) and the Action of Sodium on Camphenilone. S. V. Hintikka (*Chem. Zentr.*, 1913, i, 625 ; from *Ann. Acad. Sci. Fennicae*, 1913, **9**, 1—7). —*Camphenilolic acid*, $C_{18}H_{15}\cdot CO_2H$, is obtained by heating camphenilone with powdered potassium hydroxide, as an oil, b. p. 140—141°/15 mm., D_4^{20} 0·9820, n_D 1·45650. It forms a *chloride*, b. p. 112—114°/10 mm., a *methyl* ester, mobile oil, b. p. 203—204°/762 mm., D_4^{21} 0·9392, n_D 1·44441, and an *anilide*, $C_8H_{15}\cdot CO\cdot NHPh$, in radiating needles, m. p. 89—90°. If the acid had Wallach's formula (I) it should give a hydroxy-acid on oxidation, which should further yield the lactone, dimethylnorcampholide. It undergoes extensive decomposition, however, and the products include acetic acid and probably butyric acid.

$$\begin{array}{ccc}
\mathrm{CH_2\cdot CH\cdot CHMe_2} & \mathrm{CH_2\!-\!\!-CH_2} & \mathrm{CH_2\!-\!CH_2} \\
|\quad\ \mathrm{CH_2} & \mathrm{CH\cdot CH_2\cdot C\!-\!\!-\!\!-C\cdot CH_2\cdot CH} & \\
\mathrm{CH_2\cdot CH\cdot CO_2H} & \mathrm{CMe_2\!-\!\!-CH\cdot OH\ \ CO\!-\!\!-CMe_2} & \\
\text{(I.)} & \text{(II.)} &
\end{array}$$
When boiled with sodium in xylene, camphenilone yields a yellow, viscous *oil*, $C_{18}H_{28}O_2$ (II?), b. p. 172—174°/12 mm., D_4^{20} 1·0601, n_D 1·51547.   J. C. W.

Direct Hydrogenation of the Hydrocinnamic Esters: Preparation of β-*cyclo*Hexylpropionic Acid. Paul Sabatier and Marcel Murat (*Compt. rend.*, 1913, **156**, 751—753).—The esters of β-phenylpropionic acid like those of phenylacetic acid (compare this vol., i, 362) readily undergo direct hydrogenation in the presence of active nickel at 170—185°, giving the corresponding esters of β-*cyclo*hexylpropionic acid in a pure state. The following have been prepared :

Methyl β-cyclohexylpropionate, b. p. 222—224° (corr.), D_0^0 0·9705, D_0^{16} 0·9603, n_D^{16} 1·453.

Ethyl β-cyclohexylpropionate, b. p. 231° (corr.), D_0^0 0·9512, D_0^{17} 0·9383, n_D^{17} 1·452.

Propyl β-cyclohexylpropionate, b. p. 251—252° (corr.), D_0^0 0·9467, D_0^{15} 0·9322, n_D^{15} 1·455.

iso*Butyl* β-cyclohexylpropionate, b. p. 260° (corr.), D_0^0 0·9368, D_0^{15} 0·9281, n_D^{16} 1·456.

Whilst the densities decrease with increase in molecular weight the refractive indices remain practically constant. All these esters are readily saponified by warming with alcoholic potassium hydroxide, and with dilute sulphuric acid yield β-*cyclo*hexylpropionic acid (compare Ipatiev, A., 1909, i, 472).   W. G.

Influence of the Nature and Position of Substituents on the Stability of the Carboxyl Group in Substituted Benzoic Acids. Franz von Hemmelmayr (*Monatsh.*, 1913, **34**, 365—388. Compare Cazeneuve, A., 1895, i, 57).—The relative stability of the carboxyl group in various substituted benzoic acids was determined by boiling the acids in solution in water or aniline and estimating the proportion decomposed in a certain time. The results, which are tabulated in detail and fully discussed, show that it is difficult to draw general conclusions as to the influence of the position of substituents on the stability of the carboxyl group. The four substituents

investigated are arranged in the following descending order as regards their effect on the stability of the carboxyl group : ·OH, ·NO₂, ·Br, ·NH₂. T. A. H.

Preparation of Nuclear Nitroso-derivatives of Phenyl-glycine-o-carboxylic Acids, their Acids and Neutral Esters. J. D. RIEDEL (D.R.-P. 256461. Compare A., 1887, 729, 1114; 1909, i, 794, 645).—When a cold concentrated hydrochloric acid solution of phenylglycine-o-carboxylic acid (5 parts) is treated with sodium nitrite, it furnishes p-*nitrosophenylglycine-o-carboxylic acid hydrochloride*, decomp. about 100°; the free *base*, a green powder, condenses with p-nitrobenzonitrile to furnish an *azomethine*, red needles, m. p. 256—258°, and with benzonitrile to give a yellow *compound*.

Dimethyl p-*nitrosophenylglycine*-o-*carboxylate* has m. p. 164—165°, and the *diethyl* ester, m. p. 131°.

p-*Nitroso-o-carbomethoxyphenylglycine ethyl* ester is a green, crystalline compound, m. p. 125°, and p *nitroso-o-carboxyphenylglycine ethyl* ester has m. p. 115—116°. F. M. G. M.

Preparation of Derivatives of Arylalkyloxyacetic Acids. GESELLSCHAFT FUR CHEMISCHE INDUSTRIE IN BASEL (D.R.-P. 256756. Compare McKenzie, T., 1899, 75, 755).—a-*Ethoxy-a-phenylacetamide*, OEt·CHPh·CO·NH₂, colourless needles, m. p. 90°, is obtained when ethyl ethoxyphenylacetate, b. p. 145—147°/20 mm., is shaken with saturated ammonium hydroxide; the following derivatives have been obtained in an analogous manner.

a-*Methoxyphenylacetamide*, m. p. 110—111°, from *ethyl* a-*methoxy-phenylacetate*, b. p. 148—152°/22 mm.

p-*Tolyloxyethylacetamide*, m. p. 130—131°, from *ethyl* p-*tolyloxyethyl-acetic acid*, b. p. 160—165°/25 mm.

o-*Chlorophenoxyallylacetamide*, a colourless oil, b. p. 171—174°/21 mm., from *ethyl* o-*chlorophenoxyallylacetate*, b. p. 166—170°/25 mm.

Phenoxyallylacetamide, m. p. 77—78°, from *ethyl phenoxyallylacetate*, b. p. 163—164°/24 mm.

Phenoxyphenylacetamide, OPh·CHPh·CO·NH₂, colourless needles, m. p. 154—155°, from phenoxyphenylacetic acid; the *carbamide*,

$$OPh·CHPh·CO·NH·CO·NH_2,$$

colourless needles, has m. p. 193°. F. M. G. M.

Stereoisomeric *iso*Fenchocamphoric Acids. A. E. SANDELIN (*Annalen*, 1913, 396, 285—335).—The constitution,

$$\begin{array}{l}CMe_2·CH(CO_2H)\\CH_2·OMe(CO_2H)\end{array}\!\!>CH_2,$$
of *iso*fenchocamphoric acid has been proved by Aschan. Theoretically, six stereoisomerides are possible, four active and two racemic. Wallach has prepared the *cis-d-* and *l*-acids, and has shown that by mixture they produce the *cis-dl*-acid, which has been obtained by Aschan. The latter has also shown that the *cis-dl*-acid is partly changed to the *trans-dl*-acid by warming with glacial acetic and hydrochloric acids. The *trans-d-* and *l*-acids hitherto have been unknown, but have now been prepared by the author. A large

number of derivatives of all the acids have also been prepared for comparative purposes. The two active *cis*-acids behave alike chemically and physically, except in the sign of the rotation ; the same is true of the active *trans*-acids. The fact that the *cis*-acid can be changed to the *trans*-acid, and vice versa proves that the two are geometrical isomerides.

trans-d- and l-iso*Fenchocamphoric acids* are prepared by heating the corresponding *cis*-acids for twenty-four hours at 180—200° with a mixture of equal parts of glacial acetic acid and hydrochloric acid, D 1·20. The product, which consists of approximately equal quantities of the *trans*- and the *cis*-acids (the same product is obtained by treating the pure *trans*-acid in the same manner), is treated with acetyl chloride, and the resulting mixture of *cis*-anhydride and *trans*-acid is extracted in a Soxhlet apparatus with carbon tetrachloride, in which the *trans*-acid is insoluble. Another method of partly changing the *cis*- to the *trans*-acid is the hydrolysis of the acid chloride.

cis-d- and l-iso*Fenchocamphoric acids* crystallise in prisms, have m. p. 158—159°, K 0·00492, $[a]_D^{20}$ + 14·58° and − 14·54° respectively in alcohol, and solubility (that is, amount dissolved by 100 grams of water at 25°) 1·409 and 1·412 grams respectively ; *cis-dl-iso*fenchocamphoric acid crystallises in leaflets, and has m. p. 174—175°, K 0·00491, and solubility 0·224. *trans-d-* and l-iso*Fenchocamphoric acids* crystallise in prisms, and have m. p. 149—150·5°, K 0·00419 and 0·00421 respectively, $[a]_D^{20}$ + 4·19° and − 4·16° respectively, and solubility 0·460 and 0·458 respectively ; *trans-dl-iso*fenchocamphoric acid crystallises in leaflets, and has m. p. 173—174°, K 0 00420, and solubility 0·180.

cis-d- and l-iso*Fenchocamphoric anhydrides* crystallise in prisms, and have m. p. 98° and $[a]_D^{20}$ + 13·33° and − 13·46° respectively in benzene ; *cis-dl-iso*fenchocamphoric anhydride has m. p. 95—96°. These anhydrides are easily hydrolysed by water.

All the *iso*fenchocamphoric acids are readily esterified by the necessary alcohol and sulphuric acid, and yield, contrary to expectation, mainly the normal esters. *Methyl* cis-d-iso*fenchocamphorate* has b. p. 253—255°/764 mm., D_4^{20} 1·0484, n_D^{19} 1·45166, and $[a]_D^{15}$ + 19·17° ; the *l-ester* has b. p. 253—255°/780 mm., D_4^{20} 1·0470, n_D^{12} 1·45388°, and $[a]_D^{12}$ − 19·06°. *Methyl* cis-dl-iso*fenchocamphorate* has b. p. 252—253°/760 mm., D_4^{20} 1·0490, n_D^{20} 1·45206. *Methyl* trans-d-iso*fenchocamphorate* has b. p. 248—249°/757 mm., D_4^{20} 1·0467, n_D^{15} 1·45267, $[a]_D^{15}$ − 1·14° ; the l-*ester* has the same b. p., D_4^{20} 1·0471, n_D^{16} 1·45186, $[a]_D^{15}$ + 1·18. *Methyl* trans-dl-iso*fenchocamphorate* has b. p. 247—248°/757 mm., D_4^{20} 1·0448, $n_D^{15·5}$ 1·45176. *Ethyl* cis-d-iso*fenchocamphorate* has b. p. 269—271°/764 mm., D_4^{20} 1·0067, n_D^{20} 1·44656, $[a]_D^{20}$ + 11·52° ; the l-*ester* has b. p. 270—272°/780 mm., D_4^{20} 1·0073°, n_D^{12} 1·44926, and $[a]_D^{12}$ − 11·16°. *Ethyl* trans-d-iso*fenchocamphorate* has b. p. 266—267°/750 mm., D_4^{20} 1·0057, n_D^{16} 1·44656, $[a]_D^{15}$ − 1·05° ; the l-*ester* has the same b. p., D_4^{20} 1·0053, n_D^{20} 1·44646, and $[a]_D^{15}$ + 0·99°. *Ethyl* trans-dl-iso*fenchocamphorate* has b. p. 264—265°/750 mm., D_4^{20} 1·0035, n_D^{15} 1·44576.

a-Alkyl hydrogen *iso*fenchocamphorates, $\begin{matrix} CMe_2 \cdot CH(CO_2R) \\ CH_2 \cdot CMe(CO_2H) \end{matrix} > CH_2$, are obtained as by-products in the esterification of the acids, and also by

the action of sodium alkyloxides on the anhydrides; β-alkyl hydrogen esters are produced by the partial hydrolysis of the normal esters. These hydrogen esters are, almost without exception, viscous liquids which have not been obtained in a pure state. The dianilides of the *iso*fenchocamphoric acids are obtained from the acid chlorides and aniline in cold ether. cis-d- and l-iso*Fenchocamphordianilides* have m. p. 184—185°, and $[a]_D^{18}$ + 26·26° and − 26·53° respectively in alcohol, and the dl *anilide* has m. p. 142—144°. trans-d- and l-iso*Fenchocamphoranilides* have m. p. 190—191° and $[a]_D$ − 20·30° and + 20·69° respectively in alcohol, whilst the dl-*anilide* has m. p. 185—187°. It is noteworthy that the replacement of the two chlorine atoms of the acid chloride by the anilino-group yields only one of the two possible, geometrically isomeric dianilides, whereas their replacement by hydroxyl gives both *cis-* and *trans-iso*fenchocamphoric acids.

Diamides of the *cis*-acids cannot be prepared. By passing dry ammonia into a cold solution of the respective acid chlorides in ethyl acetate, trans-d- and l-iso*fenchocamphordiamides*, $C_{10}H_{18}O_2N_2,H_2O$, m. p. 95—96° and 95—97° respectively, $[a]_D^{17}$ − 6·18° and + 6·37° respectively in alcohol, and trans-dl-iso*fenchocamphordiamide*, $C_{10}H_{18}O_2N_2$, m. p. 202—204°, are obtained. cis-d- and l-iso*Fenchocamphorimides*, m. p. 120—121°, $[a]_D^{18}$ − 12·73° and + 12·67° respectively in alcohol, and the dl-*imide*, m. p. 122—123°, are obtained by heating the ammonium salts of the corresponding acids at 180—200° for twenty-four hours.

a-cis l-iso-*Fenchocamphoramic acid*, $\dfrac{CMe_2 \cdot CH(CO \cdot NH_2)}{CH_2 \!-\! CMe(CO_2H)} \!\!>\!\! CH_2$, is pre-
pared best by treating a cold ethereal solution of the *cis-l*-anhydride with dry ammonia and treating the concentrated aqueous solution of the product with hydrochloric acid. It has m. p. 220° (decomp.), decomposes when heated slowly, has $[a]_D^{20}$ − 11·18° in alcohol, and yields *cis-l-iso*fenchocamphoric anhydride above its m. p. a-cis-d-iso*Fenchocamphoramic acid*, m. p. 220° (decomp), $[a]_D^{20}$ + 10·99° in alcohol, and the a-cis-dl *isomeride*, m. p. 208° (decomp.), are prepared by similar methods. a-trans-d-, l-, and dl-iso*Fenchocamphoramic acids*, m. p. 210—211°, 210—211°, and 205° respectively, are obtained as by-products in the preparation of the diamides; the active acids have $[a]_D^{18}$ + 7·98° and − 7·94° respectively in alcohol.

β-cis-d- and l-iso*Fenchocamphoramic acids*, $\dfrac{CMe_2 \!-\! CH(CO_2H)}{CH_2 \cdot CMe(CO \cdot NH_2)} \!\!>\!\! CH_2$,
m. p. 180—181°, $[a]_D^{18}$ + 8·91° and − 8·75° respectively in alcohol, and the cis-dl-*isomeride*, m. p. 194—195°, are prepared by boiling the respective imides with aqueous sodium hydroxide for two hours and acidifying. The yield is quantitative, and the acids are only very slowly attacked by boiling water, crystallising therefrom in well-formed needles. β-trans-d- and l-iso*Fenchocamphoramic acids*, m. p. 179—180°, $[a]_D^{17}$ + 9·71° and − 9·57° respectively in alcohol, and the dl-*isomeride*, m. p. 155—156° (when crystallised from chloroform, the substance forms needles containing $CHCl_3$, m. p. 151—152°), are prepared by acidifying the solution obtained by boiling the respective diamides with the calculated amount of aqueous sodium hydroxide.　　　　C. S.
Behaviour of the 1-Ester of 3-Nitrophthalic Acid Towards Hydrazine. THEODOR CURTIUS and AUGUST SEMPER (*Ber.*, 1913, **46**, 1162—1171).—Miller's monoethyl 3-nitrophthalate (I) (A., 1882, 404), the constitution of which is ascertained in the present researches, has been converted into the hydrazine salt of *o*-nitrophthalic monohydrazide (II), and this into the acid hydrazide (III), and finally into the azoimide (IV).

$$
\begin{array}{cccc}
\text{NO}_2 & \text{NO}_2 & \text{NO}_2 & \text{NO}_2 \\
\text{CO}_2\text{H} & \text{CO}_2\text{N}_2\text{H}_5 & \text{CO}_2\text{H} & \text{CO}_2\text{H} \\
\text{CO}_2\text{Et} & \text{CO·NH·NH}_2 & \text{CO·NH·NH}_2 & \text{CO·N}_3 \\
\text{(I.)} & \text{(II.)} & \text{(III)} & \text{(IV.)}
\end{array}
$$
The latter substance loses hydrazoic acid when boiled with water or alcohol, forming *o*-nitrophthalic acid with water and the acid-ester (V) with alcohol. This isomeric acid-ester only gives a hydrazine salt with hydrazine, and, unlike the starting material, it is easily converted into the diethyl ester.

$$
\begin{array}{cc}
\text{NO}_2 & \text{NO}_2 \\
\text{CO}_2\text{Et} & \text{CO}_2\text{Et} \\
\text{CO}_2\text{H} & \text{CO}_2\text{·N}_2\text{H}_5 \\
\text{(V.)} & \text{(VI.)}
\end{array}
$$
When the acid-azoimide is heated in benzene or chloroform, however, it slowly loses nitrogen and yields *o*-nitroisatoic anhydride (VII). The carbimide (VIII) might have been expected, but the substance gives, on boiling with water, not a carbamide, but 6-nitro-2-aminobenzoic acid, forms a urethane only on prolonged boiling with alcohol, and gives a benzanilide and not a phenylcarbamide with aniline.

$$
\begin{array}{cccc}
\text{NO}_2 & \text{NO}_2 & \text{NH}_2 & \text{NH}_2 \\
\text{CO—O} & \text{CO}_2\text{H} & \text{CO·N·N}_2\text{H}_5 & \text{CO·NH} \\
\text{NH·CO} & \text{N:CO} & \text{CO·NH} & \text{CO·NH} \\
\text{(VII.)} & \text{(VIII.)} & \text{(IX.)} & \text{(X.)}
\end{array}
$$

When heated with dilute sulphuric acid, the substance is also deprived of the carboxyl group and converted into *m*-nitroaniline.

If the initial acid-ester be boiled with an excess of hydrazine hydrate, the nitro-group is reduced, and water eliminated from the hydrazine salt of the monohydrazide, with the formation of the hydrazi-compound (IX), which is resolved into the aminohydrazide (X) by water. This compound was also obtained from triethyl *hemi*mellitate (Schmitz, *Diss.*, Heidelberg, 1902) according to the scheme:

$$
\begin{array}{ccccc}
\text{CO}_2\text{Et} & & \text{CO·NH·NH}_2 & & \text{CO·N}_3 \\
\text{CO}_2\text{Et} & \xrightarrow{\text{N}_2\text{H}_4} & \text{CO·NH} & \xrightarrow{\text{HNO}_2} & \text{CO·NH} \\
\text{CO}_2\text{Et} & & \text{CO·NH} & & \text{CO·NH} \\
\end{array}
$$

$$
\begin{array}{cc}
& \text{NH·CO}_2\text{Et} & & \text{NH}_2 \\
\xrightarrow{\text{C}_2\text{H}_5\text{OH}} & \text{CO·NH} & & \text{CO·NH} \\
& \text{CO·NH} & & \text{CO·NH}
\end{array}
$$
For the preparation of the *hydrazine* salt of *o-nitrophthalic acid monohydrazide* (II), Miller's ester, m. p. 110°, is triturated with hydrazine hydrate. It forms colourless needles, m. p. 157°, which yield the *benzylidene* compound of the acid-hydrazide,

$$CO_2H \cdot C_6H_3(NO_2) \cdot CO \cdot NH \cdot N\!:\!CHPh,$$
in small, colourless needles, m. p. 177°, and, with hydrochloric acid, the *acid hydrazide* (III), in flat needles, m. p. above 280°, from which the *azoimide* (IV) is obtained in colourless, shimmering scales by the addition of sodium nitrite to the suspension in concentrated hydrochloric acid. After prolonged boiling with absolute alcohol the azoimide is converted into the *acid-ester* (V), which forms yellow needles, m. p. 157°, but when heated in dry chloroform the product is *o-nitroisatoic anhydride* (VII), which crystallises in pale yellow, flat needles, m. p. 215°, and is isomeric with Kolbe's nitroisatoic anhydride (A., 1885, i, 666), which gave 5-nitro-2-aminobenzoic acid on boiling with water. It gradually dissolves in boiling absolute alcohol, forming the *urethane*, $C_{10}H_{10}O_6N_2$, in faintly yellow, flat needles, m. p. 187°, which yield *m*-nitroaniline with dilute acids. It also forms the *anilide*, $C_{15}H_{11}O_3N_3$, in slender, yellow needles, m. p. 137°.

The *hydrazine* salt of the cyclic *hydrazide* of *o-aminophthalic acid* (IX) results when the starting material is heated with an excess of hydrazine hydrate. The free *hydrazide* (X) is a yellow solid, which behaves as a monobasic acid, forming *barium*, *potassium*, and *sodium* salts. It is also soluble in dilute acids, and gives a blue fluorescence in hot glacial acetic acid (compare Schmitz, *loc. cit.*).

<div align="right">J. C. W.</div>

Preparation of *αβ*-Diketonic Esters. ANDRÉ WAHL and M. DOLL (*Bull. Soc. chim.*, 1913, [iv], 13, 332—348. Compare A., 1904, i, 556; 1907, i, 217; 1911, i, 108; 1912, i, 536, 625).—This paper discusses in detail the mechanism of the reaction between "nitrous fumes" and acylacetic esters, by means of which the methylene group of the latter is converted into a carbonyl group, with the formation of *αβ*-diketonic esters. Examples of this reaction have been recorded already (*loc. cit.*). The reaction occurs in two stages: (1) the formation of an oximino-derivative of the acylacetate (A., 1904, i, 556; 1905, i, 409), and (2) the conversion of this oximino-derivative into the corresponding *αβ*-diketonic ester by the action of "nitrous fumes." The latter were obtained by treating "chamber crystals" with sodium nitrite, and as applied consisted chiefly of N_2O_3 and NO_2 (89·2%) with some NO (10%). The gas resulting from the second phase of the reaction was chiefly N_2 (54%), $N_2O_3 + NO_2$ (29%), N_2O (10%), and NO (7%), so that this phase is not unilateral. The following new compounds were prepared.

Methyl benzoylglyoxylate, D_0^0 1·233, b. p. 146—149°/12 mm., is a mobile, orange-yellow liquid, which reduces Fehling's solution and ammoniacal silver nitrate, and yields a *hydrate*, $COPh \cdot CO \cdot CO_2Me, H_2O$, m. p. 65°, crystallising in stellate groups of pearly needles. *Propyl benzoylglyoxylate*, b. p. 155—158°/12 mm., D_0^0 1·159, combines with alcohol or water, but the products are not crystalline. iso*Butyl*

benzoylglyoxylate, D_0^0 1·124, b. p. 161—164°/12 mm., yields a crystalline *monohydrate*, m. p 62—63°.

Ethyl valeroylglyoxylate, b. p. 100—125°/15 mm., was not obtained pure.   T. A. H.

Synthesis of Orsellinic Acid and Everninic Acid. KURT HOESCH (*Ber.*, 1913, 46, 886—892).—Attempts to synthesise orsellinic acid from orcinol by a process analogous to the salicylic acid synthesis yielded only the isomeric *p*-orsellinic acid. The synthesis could, however, be successfully effected by the oxidation of orcylaldehyde.

Orcylaldehyde, obtained from orcinol by the method of Gattermann (A., 1908, i, 28), was found to undergo oxidation more smoothly after converting the hydroxyl groups into methylcarbonato-groups (compare Fischer and Freudenberg, A., 1910, i, 265) by the action of methyl chlorocarbonate and· sodium hydroxide. *Dimethylcarbonato-orcylaldehyde*, $CHO \cdot C_6H_2Me \cdot (O \cdot CO_2Me)_2$, crystallises in needles, m. p. 84—85°, which turn yellow on exposure to light; *methylcarbonato-orcylaldehyde*, $CHO \cdot C_6H_2Me(OH) \cdot O \cdot CO_2Me$, obtained by the action of less methyl chlorocarbonate forms prisms, m. p. 79°. *Diethylcarbonato-orcylaldehyde*, needles, m. p. 60°, obtained analogously to the corresponding dimethylcarbonato-compound, behaves similarly to the latter towards oxidation; when treated in acetone solution at 40° with potassium permanganate, they are oxidised to dimethylcarbonato-orsellinic acid (compare Fischer and Hoesch, A., 1912, i, 859) and *diethylcarbonato-orsellinic acid*, prisms, m. p. 112° (decomp.) respectively. These acids are hydrolysed by *N*-sodium hydroxide solution at room temperature, giving satisfactory yields of orsellinic acid,

$$C_6H_2Me(OH)_2 \cdot CO_2H.$$

If orcylaldehyde is cautiously methylated by methyl sulphate and 2*N*-sodium hydroxide in acetone solution, *everninaldehyde* (2-hydroxy-4-methoxy-6-methylbenzaldehyde) is obtained as needles, m. p. 65°. When heated with anhydrous sodium acetate and acetic anhydride in a sealed tube for five hours at 170—180°, everninaldehyde is converted

into *7-methoxy-5-methyl-1 : 2-benzopyrone*, $OMe \cdot C_6H_2Me \Big\langle \begin{smallmatrix} CH=CH \\ O——CO' \end{smallmatrix}$

long needles, m. p. 146°, which dissolve in concentrated sulphuric acid, giving a blue fluorescence; the success of this synthesis confirms the structure already assumed for everninaldehyde (Fischer and Hoesch, *loc. cit.*). When an acetone solution of everninaldehyde is carefully treated with methyl chlorocarbonate and sodium hydroxide, *methylcarbonatoeverninaldehyde*, $OMe \cdot C_6H_2Me(O \cdot CO_2Me) \cdot CHO$, needles, m. p. 77°, which redden in the light and are phototropic, is obtained. This is oxidisable by potassium permanganate with care to methylcarbonato-everninic acid, silky needles, which decompose near 100°, and can be hydrolysed by *N*-sodium hydroxide at the ordinary temperature to everninic acid, $OMe \cdot C_6H_2Me(OH) \cdot CO_2H$.   D. F. T.

Hydrogenation of Santonin. HEINRICH WIENHAUS and WOLFGANG FELIX VON OETTINGEN (*Annalen*, 1913, 397, 219—246).— By reduction by the Paal-Amberger method, santonin absorbs four atomic proportions of hydrogen, and yields two stereoisomeric tetra-

hydrosantonins. Hence the formulæ of Cannizzaro and Andreocci and of Angeli and Marino, which contain only one ethylenic linking, are disproved. The formulæ of Cannizzaro and Gucci and of Francesconi and Cusmano (A., 1908, i, 272) are permissible, and of the two, the

former, $\begin{matrix} \text{CH}_2 \cdot \text{CMe} \vdots \text{C} \cdot \text{CH}_2 \cdot \text{CH} \text{-----O} \\ \text{CO} \cdot \text{CMe} = \text{C} \cdot \text{CH}_2 \cdot \text{CH} \cdot \text{CHMe} \end{matrix} \Big\rangle \text{CO}$, is preferable.

When the hydrogenation of santonin is discontinued after 1 mol. of hydrogen has been absorbed, it is found, in accord with Paal's experience with substances containing a conjugated system (A., 1912, i, 703), that the addition does not occur in the sense of Thiele's theory; in other words, one half of the santonin is completely reduced, the other half is unattacked.

Santonin is so readily reduced that 50 grams in methyl alcohol, in the presence of 1 gram of palladous chloride, absorbed 10 litres (at 15° and 745 mm.) of hydrogen in ten minutes; the reduction proceeds even with flocculent (non-colloidal) palladium. The products are α- and β-tetrahydrosantonins, the separation of which is effected by taking advantage of the very slight tendency of β-tetrahydrosantonic acid (see below) to lactone-formation.

α-*Tetrahydrosantonin*, $C_{15}H_{22}O_3$, m. p. 158°, colourless, rectangular leaflets, does not become yellow in light, is unchanged by the action of zinc-dust and warm acetic acid, and forms an *oxime*, m, p. 235—237°, and *semicarbazone*, m.p. 256—258° (decomp.). β-*Tetrahydrosantonin*, $C_{15}H_{22}O_3$, m. p. 105°, stout plates, forms an *oxime*, m. p. 182°, and *semicarbazone*, m. p. 248—250° (decomp.).

During the reduction of anhydrous santoninoxime by the Paal-Amberger method, the oximino-group is attacked, since ammonia and α-tetrahydrosantonin have been isolated from the products. The reduction of aqueous sodium santonate in a similar manner yields α-*tetrahydrosantonic acid*, $C_{15}H_{24}O_4, H_2O$, m. p. 115° (decomp.) (anhydrous, 135—145°), rhombohedral crystals (*sodium* salt, colourless needles or leaflets), and β-*tetrahydrosantonic acid*, $C_{15}H_{24}O_4$, m. p. 200° (decomp.), or 192° slowly heated, colourless plates, which form an *oxime*, $C_{15}H_{25}O_4N$, m. p. 218—220°.

By warming with aqueous sodium hydroxide or carbonate and then acidifying, α-tetrahydrosantonin is converted into α-tetrahydrosantonic acid, which is readily changed back to the lactone by heating, or by keeping its ethereal solution. In a similar manner, β-tetrahydrosantonin is converted into β-tetrahydrosantonic acid. This acid is more stable than the α-isomeride, but is re-converted into β-tetrahydrosantonin by heating at 200° under reduced pressure.

Attempts to convert α-tetrahydrosantonin or the acid into the corresponding β-compounds, and vice versa, have been unsuccessful.

Whilst santonin itself has $[\alpha]_D^{15}$ − 171·70° in methyl alcohol, α-tetrahydrosantonin has a mean value + 17·1° ($[\alpha]_D$ of the oxime in chloroform increases from − 38·05° to − 53·07° with increase of the concentration from 1·63% to 3·34%); β-tetrahydrosantonin has $[\alpha]_D + 41·08°$ when prepared directly from santonin and 9·27° when obtained from the β-acid; α-tetrahydrosantonic acid has $[\alpha]_D + 20·00°$, and the β-acid has $[\alpha]_D + 2·18°$ (both prepared from the sodium salts). C. S.

Santonin. XI. Tetrahydrosantonin. EDGAR WEDEKIND and
E. BENIERS (*Annalen*, 1913, **397**, 246—254. Compare A., 1908, i,
183).—Many of the authors' results are identical with those obtained
by Wienhaus and von Oettingen (preceding abstract). However, by
the reduction of santonin in acetone by hydrogen ($1\frac{1}{4}$ atmospheres) in
the presence of palladous chloride and gum arabic, they have been
unable to isolate β-tetrahydrosantonin. The m. p. of a-tetrahydro-
santoninoxime is given as 219—220°, and that of the *phenylhydrazone*
as 205° (decomp.). a-Tetrahydrosantonin and nitric acid, D 1·4, yield
a-*dinitrotetrahydrosantonin*, $C_{15}H_{20}O_7N_2$, decomp. 187°, large, colourless
plates, $[a]_D + 105\cdot05°$ in alcohol and 90·22° in chloroform.

By bromination in chloroform at 35—40°, a-tetrahydrosantonin
yields a-*bromotetrahydrosantonin*, $C_{15}H_{21}O_8Br$, decomp. 147°, colourless,
prismatic needles, $[a]_D + 9\cdot09°$ in chloroform.   C. S.

Preparation of 1-Aminoanthraquinone-2-carboxylic Acids
and their Derivatives. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P.
256344. Compare A., 1912, i, 979).—*Ethyl* 1-op-*aichloroanilino-
anthraquinone-2-carboxylate*, coppery-red needles, is obtained when
ethyl 1-*chloroanthraquinone-2-carboxylate* (yellow leaflets, m. p. 142°)
is boiled for five to six hours with *op*-dichloroaniline in nitro-
benzene solution in the presence of cuprous chloride and sodium
acetate ; the free *acid* obtained by its hydrolysis (alcoholic potassium
hydroxide) is a scarlet-red powder. *Methyl* 1-*chloroanthraquinone-2-
carboxylate*, m. p. 164°, can also be employed in this reaction. *Ethyl*
1 : 1'-*anthraquinonylaminoanthraquinone-2-carboxylate* forms scarlet-red
needles and the free *acid* a violet powder, whilst the isomeric *com-
pounds* from ethyl 1-chloroanthraquinone-2-carboxylate with 2-amino-
anthraquinone consist of orange-yellow leaflets and a red powder
respectively. The *compound* from 1-amino-4-hydroxyanthraquinone
and ethyl 1-chloroanthraquinone-2-carboxylate forms violet-blue
needles.

Ethyl 1-*nitroanthraquinone-2-carboxylate*, yellow leaflets, m. p.
232—233°, when condensed with *op*-dichloroaniline gives rise to a
compound, dark red needles ; the free *acid* is a red powder.
                                                      F. M. G. M.

Esters of Polycinnamic Acid. CARL LIEBERMANN and M.
KARDOS (*Ber.*, 1913, **46**, 1055—1066).—In continuation of previous
work (A., 1911, i, 370) on the polymerisation of esters of cinnamic
acid, the authors have investigated the two allyl polycinnamates
described by Seeligmann (*Diss.*, Karlsruhe, 1906). These two esters,
which are termed allyl polycinnamate *A* and *B*, are formed by heating
allyl cinnamate in sealed tubes at 210°.

The ester *A* is obtained by heating for six hours, and isolated from
the resulting liquid by dissolving in benzene and precipitating with a
mixture of alcohol and ether. It separates in heavy, white flocks,
sintering at 190—200°, but possesses no definite m. p.

The ester *B* is best prepared by heating allyl cinnamate for fifteen
hours and extracting the product with benzene, when it is obtained
as a white powder, which becomes brown and decomposes at about

300°; it differs from the ester *A* in being insoluble in benzene and chloroform.

The two polymerides are hydrolysed by boiling with 25% alcoholic potassium hydroxide, but the amount of allyl alcohol produced is only 10—12% of that to be expected on the assumption that the polymerides are allyl esters of polycinnamic acid $(C_9H_8O_2)_x$. The conclusion is therefore drawn that the double linking of the allyl groups takes part in the polymerisation after the manner indicated in the following formula:
$$\begin{array}{c} CH_2 \cdot CHMe \cdot CPh \cdot CH \cdot CO_2 \cdot C_3H_5 \\ | \\ O - CO - CH - CHPh \end{array}.$$

This view is also confirmed by the behaviour of the ester *A* towards bromine. It combines with bromine very slowly, and after twenty-four hours yields a *bromo*-compound, $(C_{12}H_{12}O_2Br)_x$, the amount of bromine uniting with the ester being only half that which would have been combined had the allyl groups remained intact.

Both polymerides are hydrolysed by alcoholic potassium hydroxide to the corresponding *acids*, which form white, amorphous powders, sintering at 180—190° (decomp. 210—220°), and closely resemble one another

The above esters differ from that obtained by the polymerisation of allyl cinnamate by exposure to light, in solubility, and in being hydrolysed by alkalis.

Allyl cinnamate combines almost instantly with bromine (1 mol.) in chloroform solution, yielding *αβ-dibromopropyl cinnamate* as a viscid oil. Combination with a second molecule takes place more slowly, resulting in the formation of *αβ-dibromopropyl αβ-dibromopropionate*, which crystallises in white needles, m. p. 69—71°.

On exposure to light for nine months, allyl cinnamate yields a *polymeride*, which is precipitated by methyl alcohol in white flocks, m. p. above 300°, and is not hydrolysed by alcoholic potassium hydroxide.

The *polymerides* of benzyl cinnamate (decomp. 270°) and octyl cinnamate have been prepared in a similar manner.   F. B.

Methylcarbonato-derivatives of Phenolcarboxylic Acids and their Use for Synthetic Operations. VIII. Derivatives of Orsellinic and α-Resorcylic [3 : 5-Dihydroxybenzoic] Acids. EMIL FISCHER and HERMANN O. L. FISCHER (*Ber.*, 1913, 46, 1138—1148).—The difficulties attendant on the conversion of dimethylcarbonato-orsellinic acid (3 : 5-dimethylcarbonato-*o*-toluic acid) into its chloride have been overcome (compare A., 1912, i, 860). By coupling the latter with orsellinic acid, the authors have been able to prepare dimethylcarbonato - orsellinoylorsellinic acid (annexed formula), which, when hydrolysed, gives a diorsellinic acid identical with the natural lecanoric acid. A series of compounds has also been prepared from α-resorcylic acid.

Dimethylcarbonato-orsellinyl chloride, $C_6H_2Me(O \cdot CO_2Me)_2 \cdot COCl$,
m. p. 53—54°, is obtained by the action of phosphorus pentachloride on dimethylcarbonato-orsellinic acid suspended in chloroform. In suitable circumstances it reacts readily with ethyl alcohol, the corresponding *ethyl* ester being probably formed. In alkaline acetone solution it condenses with *p*-hydroxybenzoic acid, forming 4-dimethylcarbonato-orsellinoyloxybenzoic acid,

$$C_6H_2Me(O \cdot CO_2Me)_2 \cdot CO \cdot O \cdot C_6H_4 \cdot CO_2H,$$
m. p. 203—205° (corr. decomp.), after previous softening at about 190°, which in aqueous alcoholic solution does not give a characteristic coloration with ferric chloride. The alkaline salts are sparingly soluble in water. When heated with ammonia, the didepside, *4-orsellinoyloxybenzoic acid,* is obtained. Difficulty was experienced in obtaining the latter in the crystalline form until a nucleus of the crystalline acid was isolated by decomposition of the *pyridine* salt. The air-dried acid contains $1H_2O$. It has m. p. about 209° (corr. decomp.) after previous softening at about 180°, the value found depending greatly on the mode of heating.

Dimethylcarbonato-orsellinoylorsellinic acid, needles, m. p. 185—187° (corr. decomp.), is obtained by the gradual addition of a solution of dimethylcarbonato-orsellinoyl chloride in acetone to a well-cooled solution of orsellinic acid in acetone and *N*-sodium hydroxide. In aqueous alcoholic solution it gives an intense reddish-violet coloration with ferric chloride. By repeated treatment with methyl chloroformate and alkali in aqueous acetone solution, it yields a crystalline *product,* which gives no coloration with ferric chloride. This can be separated by means of potassium carbonate into a soluble portion, probably *trimethylcarbonatolecanoric acid,* and an insoluble portion which is being investigated. Aqueous sodium hydroxide slowly converts dimethylcarbonato-orsellinoylorsellinic acid into lecanoric acid, colourless needles, having no definite m. p. When quickly heated it softens at about 170°, and is completely melted at 175° with brisk evolution of gas. The air-dried acid contains $1H_2O$. Identity of this product with natural lecanoric acid was established by comparison of m. p., colorations with ferric chloride and bleaching powder, solubility, and crystal form of the two substances, and, further, by the transformation of each into the *trimethyl ether* of *methyl lecanorate,* $C_{30}H_{22}O_7$. The product from the synthetic acid had m. p. 147—148° (corr.), whilst that from the natural acid had m. p. 146—147° (corr.) after softening at 140°. A mixture of the two had m. p. 145—146·5°.

3 : 5-*Dimethylcarbonatobenzoic acid,* prepared by the action of methyl chlorocarbonate on a solution of 3 : 5-dihydroxybenzoic acid in *N*-sodium hydroxide, has m. p. 161—164° (corr.) after slight previous softening. Phosphorus pentachloride converts it into the corresponding *chloride,* colourless needles, m. p. 109—110° (corr.), which, when coupled with *p*-hydroxybenzoic acid in the usual manner, yields 4-(3 : 5-dimethylcarbonatobenzoyl)oxybenzoic acid, $C_6H_3(O \cdot CO_2Me)_2 \cdot CO \cdot O \cdot C_6H_4 \cdot CO_2H$, needles, m. p. 161—163° (corr.).

When treated with aluminium chloride and benzene during an hour at 70—75°, and then during forty-five minutes at 75—80°, 3 : 5-dimethylcarbonatobenzoyl chloride yields 3 : 5-*dihydroxybenzophenone,* which separates from water with $1H_2O$. The dry substance has m. p.

160—162° (corr.). If the temperature in the above process is maintained at 40—45° during five hours, no hydrogen chloride is evolved, and a pale yellow *oil* is subsequently obtained, which crystallises when brought into contact with light petroleum. The product, which has not yet been obtained in the pure state, contains the methylcarbonato-groups, and is transformed by alkali into 3 : 5-dihydroxybenzophenone. H. W.

Tannin and the Synthesis of Similar Substances. III. Compounds of High Molecular Weight. EMIL FISCHER and KARL FREUDENBERG (*Ber.*, 1913, **46**, 1116—1138).—The authors have continued their previous work (A., 1912, i, 471, 887), and describe a convenient method of preparing *m*-digallic acid in larger quantities. The properties of this acid resemble those of the digallic acid previously described as the para-compound (A., 1908, i, 893) so closely that the two substances are in all probability identical. It differs considerably, however, from the *m*-digallic acid described by Nierenstein (A., 1910, i, 265).

A series of compounds of high molecular weight has been obtained by the use of tribenzoylgallic acid ; for example, hexa-(tribenzoylgalloyl)-mannitol. In the analysis of this and similar compounds, a difficulty is experienced in that the differences in the percentages of carbon and hydrogen are not sufficiently great to allow conclusions to be drawn with regard to the number of acyl groups present. This has been overcome by the introduction of halogen atoms into the molecule, and a series of substances has been prepared from 2 : 4 : 6-tribromophenol-*d*-glucoside and *p*-iodophenylmaltosazone, of which the most interesting is *hepta-(tribenzoylgalloyl)-p-iodophenylmaltosazone,*

$$C_{220}H_{142}O_{58}N_4I_2,$$
mol.-wt. 4021. The molecular weight of this and similar substances has been determined in bromoform solution, the observed values being found to agree with those theoretically required without greater divergence than is frequently encountered with much more simply constituted, crystalline substances.

Carbonylogallic acid (4 : 5 - *carbonato* - 3 - *hydroxybenzoic acid*), $OC{<}^O_O{>}C_6H_2(OH)\cdot CO_2H$, is obtained by the addition of a solution of carbonyl chloride in toluene to a well-cooled mixture of gallic acid, acetone, and 2*N*-sodium hydroxide (3 mols.), and subsequent acidification of the product with hydrochloric acid. A full description of the apparatus employed is given. The acid has m. p. about 255° (corr. decomp.). It is sparingly soluble in cold water, and decomposed by hot water with regeneration of gallic acid. Hot methyl alcohol converts it into 3-methylcarbonatogallic acid. In alcoholic solution it gives a faint coloration with ferric chloride, which increases in intensity on keeping. It is transformed by diazomethane into *methyl 4 : 5-carbonato-3-methoxybenzoate,* $OC{<}^O_O{>}C_6H_2(OMe)\cdot CO_2Me$, long needles, m. p. 134° (corr.), which, when boiled with water, probably yields methyl 4 : 5-dihydroxy-3-methoxybenzoate. The latter is converted by the successive action of sodium hydroxide and hydro-

chloric acid into 4 : 5-dihydroxy-3-methoxybenzoic acid, which is apparently identical with the acid obtained by Vogl (A., 1899, i, 698). The latter gives m. p. 199—200° (uncorr.), whereas the authors find about 220° (corr. decomp.), but point out that the observed m. p. depends greatly on the mode of heating.

m-Digallic acid is prepared by the alternate addition of N-potassium hydroxide and of a solution of trimethylcarbonatogalloyl chloride in acetone to a cooled solution of carbonylogallic acid in acetone and N-potassium hydroxide. The product is treated with N-sodium hydroxide and subsequently with hydrochloric acid, when m-digallic acid, needles, m. p. about 280° (corr. decomp.) after softening at 260° (corr.), is obtained, the yield being 45% of the theoretical. The acid dissolves in water at 25° in the proportion 1 : 860, and gives a deep bluish-black coloration with ferric chloride. With aqueous potassium cyanide solution, it yields, after ten seconds, a pink coloration which disappears after a time, but returns on shaking the solution. When boiled during six hours with 1% hydrogen peroxide solution, it yields a dark brown coloration, but no precipitate. With 10% aqueous hydrogen peroxide under similar conditions, a clear solution is formed. In these particulars, the acid differs markedly from Nierenstein's m-digallic acid (*loc. cit.*). With diazomethane, it yields methyl 5(3′ : 4′ : 5′)-trimethoxybenzoyloxy-3 : 4-dimethoxybenzoate, which is identical with the product obtained previously (A., 1912, i, 888). Acetic anhydride converts it into *penta-acetyl-m-digallic* acid, needles, m. p. 193—194° (corr.), after softening at about 184° (Nierenstein's m-digallic acid gave a penta-acetyl derivative, m. p. 211—214°). An attempt to prepare the corresponding pentabenzoyl derivative was unsuccessful.

3 : 4 : 5-*Trimethoxybenzoic anhydride*, microscopic needles, m. p. 160—161° (corr.), is obtained by the action of 3 : 4 : 5-trimethoxybenzoyl chloride on 3 : 4 : 5-trimethoxybenzoic acid in chloroform solution in the presence of quinoline. Similarly, the mixed *anhydride* of 3 : 4 : 5-trimethoxybenzoic acid and pentamethyl-m-digallic acid, needles, m. p. 165—166° (corr.), is obtained from 3 : 4 : 5-trimethoxybenzoyl chloride and pentamethyl-m-digallic acid, and is identical with a product previously obtained during the synthesis of pentamethyl-m-digallic acid (A., 1912, i, 888).

Pentamethyl-p-digallic acid is obtained in 75% yield from 3 : 4 : 5-trimethoxybenzoyl chloride and syringic acid according to the method employed in preparing the m-isomeride. It forms leaflets, m. p. 221—222° (corr.). The methyl ester, prepared by the action of diazomethane on the acid, has m. p. 172—173° (corr.), whereas Mauthner (A., 1911, i, 725) found m. p. 169—170°.

Tribenzoylgallyl chloride, $C_6H_2(OBz)_3 \cdot COCl$, needles, m. p. 124—126° (corr.), is obtained by the action of phosphorus pentachloride on tribenzoylgallic acid in the presence of chloroform at the ordinary temperature. The corresponding ethyl *ester* has m. p. 126—128° (corr.), whilst the *anhydride*, $C_{56}H_{34}O_{15}$, needles, has m. p. 195—196°, and is more stable towards alcohol than simple substances of this class.

Tetra-(tribenzoylgalloyl)-tribromophenol-d-glucoside,
$$(C_{28}H_{17}O_7)_4 C_6H_7O_6 \cdot C_6H_2Br_3,$$

is prepared by the addition of tribromophenol-d-glucoside to a solution of tribenzoylgalloyl chloride and quinolin in chloroform. It is a white, amorphous powder, which softens at about 130°, and melts to a clear syrup at about 155°. In tetrachloroethane solution, it has $[\alpha]_D^{20} - 31\cdot01°$. *Hexa-(tribenzoylgalloyl)-mannitol*, obtained in a similar manner, has $[\alpha]_D^{20} + 19\cdot63°$ in tetrachloroethane solution. It soften at about 125°, and is completely molten at about 150°.

Tetrabenzoylphenylglucosazone, $C_6H_6O_4Bz_4(N_2HPh)_2$, softens at about 100°, is completely molten at about 130°, and begins to decompose at about 140°. When dissolved in acetylene tetrachloride, it has $[\alpha]^{20} - 12\cdot16°$ for the Auer light.

p-*Iodophenylmaltosazone*, $C_{12}H_{20}O_9(N_2H\cdot C_6H_4I)_2$, prepared by the action of p-iodophenylhydrazine on maltosone in aqueous-alcoholic solution, crystallises in yellow needles, m. p. 208° (corr.), after slight previous softening, the m. p., however, varying according to the mode of heating. The solution in pyridine exhibits mutarotation, constant values being probably obtained after three days. For one specimen, $[\alpha]_D^{20}$ was found to be $+83\cdot44°$ after eight minutes, $+66\cdot51°$ after thirty-two hours, $+66\cdot11°$ after forty-eight hours. When treated with tribenzoylgalloyl chloride at the ordinary temperature in the presence of quinoline and chloroform, p-iodophenylmaltosazone yields *hepta-(tribenzoylgalloyl)-p-iodophenylmaltosazone*,

$$(C_{28}H_{17}O_7)_7C_{12}H_{13}O_9(N_2H\cdot C_6H_4I)_2,$$
amorphous, pale yellow powder, which softens at about 145°, and is melted to a red liquid at 160°. In tetrachloroethane solution it has $[\alpha]^{20} - 8\cdot75°$.

The molecular weight of the above substances of high molecular weight was determined cryoscopically in bromoform solution, care being taken to obtain them free from any trace of adhering solvent. From experiments on the molecular weight of naphthalene dissolved in bromoform, the value 143 was adopted as constant for the solvent. The following mean results were obtained, the theoretical values being enclosed in brackets : tribenzoylgallic anhydride, 954 (946) ; tetra-(tribenzoylgalloyl)-tribromophenol-d-glucoside, 2036 (2349) ; hexa-(tri-benzoylgalloyl)-mannitol, 2781 (2967) ; hepta-(tribenzoylgalloyl)-p-iodophenylmaltosazone, 3503 (4021). H. W.

Salicylaldehydephenylhydrazone. GEORG LOCKEMANN and FRANZ LUCIUS (*Ber.*, 1913, 46, 1012—1021. Compare this vol., i, 296).—Salicylaldehyde phenylhydrazone (compare Biltz, A., 1894, 584) can appear in isomeric forms, which, however, do not differ in melting point, but in crystalline form, colour, and solubility. Their formation depends on the conditions of crystallisation and the illumination. The isomerism is therefore physical and not chemical, as supposed by Biltz.

The α-hydrazone is formed in rectangular prisms on slow crystallisation from dilute alcohol or benzene ; these are pale or dark green when light is excluded, greyish or brownish-yellow in its presence. The green form occurs in presence of acetic acid ; with ammonia the yellow modification is formed.

The β-hydrazone is deposited on quick crystallisation in colourless

needles, which become greenish-yellow on exposure to light. The γ-modification separates from light petroleum in bunches of green needles, which become yellow or orange on exposure. In all three modifications the coloration brought about by light slowly reverses in the dark. All three soften between 135° and 140°, m. p. 142—143°.

When benzoylated in pyridine solution, according to the proportion of benzoyl chloride, the *O*-monobenzoyl or the *O,N*-dibenzoyl derivatives are obtained. When sodium hydroxide is present, the dibenzoyl derivative is the main product, more or less hydrazone remaining unattacked.

On reduction of the dibenzoyl derivative with zinc dust and acetic acid, benzanilide and *o*-hydroxybenzylbenzamide,

$$OH \cdot C_6 H_4 \cdot CH_2 \cdot NH \cdot CO \cdot C_6 H_5,$$
are formed.

o-Benzoylhydroxybenzylbenzamide, prepared by benzoylating by the Schotten-Baumann process, forms colourless needles, m. p. 141—142°.

When hydrolysed either with cold alcoholic potassium hydroxide or warm alcoholic ammonia, *N*-benzoyl *o*-hydroxybenzaldehydephenyl-hydrazone is obtained; it gives a dark bluish-green ferric chloride coloration. E. F. A.

Condensation Product of Piperonaldehyde with Ethyl Urethane. I. G. BIANCHI (*Gazzetta*, 1913, 43, i, 237—243).— When these substances are heated for half an hour on the water-bath with a little hydrochloric acid, *piperonylidenebisurethane*, $C_{15}H_{18}O_6N_2$, m. p. 177—178°, is obtained; it crystallises in colourless needles. R. V. S.

Preparation of Cyclic Ketones. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 256622).—When adipic acid, its homologues, or substitution products are heated they furnish satisfactory yields of the corresponding cyclic ketones; this reaction is conveniently carried out under reduced pressure, in the presence of an inert gas, and of a catalytic reagent, such as oxides, carbonates or other salts of the alkali metals, alkaline earths, or magnesium; of salts of the heavy metals, such as iron, nickel, cobalt, manganese, or uranium; or of phosphoric, boric, or other acids.
*cyclo*Pentanone, b. p. 49—50°/31 mm., is obtained in quantitative yield from adipic acid at 290—295° in the presence of barium hydroxide; with uranium nitrate the yield is 85%, and with ferrous sulphate 90%.

2-Methyl*cyclo*pentanone, b. p. 38°/11 mm. and 57—59°/29 mm., is similarly obtained at 300—305° from β-methyladipic acid, whilst suberic acid furnishes *suberone* (b. p. 179°) at 320—325° in the presence of iron. F. M. G. M.

Terpenes and Ethereal Oils. CXV. OTTO WALLACH (*Annalen*, 1913, 397, 181—219).—A systematic examination has hitherto not been made of the problem how the position of the oxygen atom in a cyclic ketone influences the b. p. Recent examples in the literature

lead the author to the generalisation that in saturated, isomeric, cyclic ketones containing the same substituents the b. p. is lowest when the heaviest substituent is nearest to the oxygen atom and highest when this substituent is situated as far as possible from the oxygen atom. Since dihydro*iso*camphor has b. p. 211° and carvomenthone has b. p. 220—221°, the generalisation furnishes corroborative evidence that dihydro*iso*camphor is not 1-methyl-5-*iso*propyl*cyclo*-hexan-2-one (compare A., 1912, i, 878).

Much more complicated and difficult is the problem of the relations between the constitutions and the b. p.'s of unsaturated cyclic ketones, since in such substances the position of the ethylenic linking must also be taken into account. By reference to the b. p.'s and the constitutions of many unsaturated cyclic ketones, the author shows that (i) ketones in which the ethylenic group and the carbonyl group form a conjugated system have a higher b. p. than isomeric ketones in which such a system does not obtain, and, moreover, that the b. p. is higher when the ethylenic linking in the conjugated system is part of the carbo-cyclic nucleus than when it is attached semicyclically or is present in a side-chain; for example, Δ^1-menthen-3-one, b. p. 235°, pulegone, b. p. 221—222°, and also carvenone, b. p. 232—233°, and dihydro-carvone, b. p. 221—223°; (ii) the replacement of the hydrogen atom in the system $\cdot C{:}CH{\cdot}CO\cdot$ by an alkyl group R is accompanied by a fall in the b. p. which is the more pronounced the greater is the molecular weight of R; for example, 1-methyl-5-*iso*propyl-Δ^1-*cyclo*hexen-3-one, b. p. 244°, Δ^1-menthen-3-one, b. p. 235°, carvotanacetone, b. p. 228—229°, 1-methyl-2-*iso*propyl-Δ^1-*cyclo*hexen-3-one, b. p. 216—217°, and Δ^4-menthen-3-one, b. p. 211°, and (iii) the fall in the b. p. by the conversion of unsaturated ketones of the type ⬡—COMe into saturated ketones of the type $C_6H_{11}\cdot COMe$ is about 19°, and is therefore distinctly greater than the fall, about 3—4°, in the b. p. caused by the conversion of ⬡—$CH_2{\cdot}COMe$ into $C_6H_{11}{\cdot}CH_2{\cdot}COMe$.

1:4-Dimethyl-Δ^6-cyclohexen-2-oneoxime, $NOH{:}C{<}^{CMe{=\!=}CH}_{CH_2\cdot CHMe}{>}CH_2$, m. p. 92—93°, and another *substance*, m. p. 169°, which is apparently an isomeride, are obtained by warming the nitrosochloride of 1:4-dimethyl-Δ^1-*cyclo*hexene with sodium acetate in glacial acetic acid. By hydrolysis, the former yields *1:4-dimethyl-Δ^6-cyclohexen-2-one* b. p. 189—190°, D^{22} 0·938, n_D^{22} 1·4753 (*semicarbazone*, m. p. 165°), which is oxidised to *p*-xylenol by ferric chloride and glacial acetic acid.

By reduction of Paal's method, 1:4-dimethyl-Δ^6-*cyclo*hexen-2-one yields 1:4-dimethyl*cyclo*hexan-2-one, b. p. 178°, D^{20} 0·9025, n_D^{20} 1·4446 (oxime, m. p. 108—109°, semicarbazone, m. p. 175—176°), which is also obtained by warming 1:4-dimethyl*cyclo*hexan-1:2-diol with dilute sulphuric acid. The saturated ketone and its oxime and semicarbazone have been described, frequently but erroneously, in the literature. By oxidation with chromic and dilute sulphuric acids, it is converted into δ-acetyl-β-methylvaleric acid (semicarbazone, m. p. 146—147°), which in turn is oxidised to β-methyladipic acid by sodium hypobromite.

By reactions similar to the preceding, tetrahydro-*m*-xylene nitroso-chloride is converted successively into 1 : 3-*dimethyl-Δ²-cyclohexen-4-oneoxime*, 1 : 3-*dimethyl-Δ²*-cyclohexen-4-one (*semicarbazone*, m. p. 194—195°), and 1 : 3-dimethyl*cyclo*hexan-4-one (this vol., i, 278).

1- imethyl*cyclo*hexan-5-one, b. p. 181·5—182°, D¹⁹ 0·895, n_D 1·4425 (semicarbazone, m. p. 201°), and 1 : 3-dimethyl*cyclo*hexan-2-one, b. p. 174·5°, D²⁰ 0·9140, n_D 1·4476 (oxime, m. p. 114—115°, semi-carbazone, m. p. 176—177°), have been prepared and their physical constants and those of the oximes and semicarbazones compared with the values recorded by other investigators.

[With LOUIS AUGSPURGER.]—By reactions similar to the preceding, 1-methyl-4-ethyl-Δ³-*cyclo*hexene nitrosochloride has been converted successively into 1-*methyl-4-ethyl-Δ³*-cyclohexen-5-oneoxime, m. p. 59—60°, 1-*methyl-4-ethyl-Δ³*-cyclohexen-5-one, b. p. 203—204°, D¹⁹ 0·9310, n_D 1·4759 (*semicarbazone*, m. p. 152—153°), and 1-methyl 4-ethyl*cyclo*hexan-5-one, b. p. 197°, D²⁰ 0·9000, n_D 1·4485 (semicarbazone, m. p. 178—181°, oxime, m. p. 80°). By oxidation with chromic acid the last substance yields a ketonic *acid*, $CO_2H·CH_2·CHMe·CH_2·CH_2·COEt$ (*semicarbazone*, m. p 145°.

1-iso*Propyl*cyclo*hexan-4-one*, b. p. 214—214·5°, D¹⁹ 0·9175, n_D^{19} 1·4561, (*dibenzylidene* compound, m. p. 105°), is obtained by the reduction of 1-*isopropyl-Δ¹-cyclo*hexen-4-one (A., 1908, i, 424) by Paal's method. 1-Methyl-3-*isopropyl-Δ⁶-cyclo*hexen-5-one, b. p. 244° (decomp.), D²¹ 0·9340, n_D^{21} 1·4865 (semicarbazone, m. p. 167°), is reduced by Paal's method to 1-methyl-3-*iso*propyl*cyclo*hexan-5-one, b. p. 221—223°, D²⁰ 0·8965, n_D 1·4541.

[With RUD. MÜLLER and FR. HENJES.]—The low b. p., 212°, of Δ⁴-menthen-3-one, in comparison with those of the isomerides, Δ¹-menthen-3-one, 235—237°, carvenone, 232—233°, and carvotan-acetone, 228—229°, led the authors to the opinion that an error must have been made either in the b. p. or in the constitution (compare Auwers, A., 1909, i, 592). It is now shown that no error had been committed. *i*-Δ⁴-Menthen-3-one, prepared from *i*-menthene, has b. p. 212—213°, D²⁰ 0·9165, n_D 1·4726, whilst *l*-Δ⁴-menthen-3-one, prepared from menthol, is a yellow liquid having b. p. 211—212°, D¹⁸ 0·919, n_D 1·4729, and [α]_D − 67·46° in methyl alcohol. The active substance forms a *semicarbazone*, m. p. 170—171°, and a *dibenzylidene* derivative, yellow needles, m. p. 140—141°, [α]_D − 58·41° in chloroform. The constitution of the active menthenone is proved by its reduction to *l*-menthone by Paal's method, and ultimately to *l*-menthol by sodium and alcohol. The constitution of the *i*-menthenone has been proved by the synthesis of the ketone from 1-methyl*cyclo*hexan-4-one and magnesium *iso*propyl iodide, the resulting alcohol being dehydrated by dilute sulphuric acid, and the 1-methyl-4-*iso*propyl-Δ³-*cyclo*hexene being converted through the nitrosochloride into the menthenoneoxime. The low b. p. of Δ⁴-menthen-3-one, therefore, must be due to the position of the *iso*propyl group between the carbonyl group and the ethylenic group (compare above).

[With FR. HENJES.]—Since little is accurately known of the deriv-atives of *i*-menthone, a large quantity of this ketone has been prepared by reducing Δ¹-menthen-3-one by Paal's method. It has b. p. 210°,

D^{20} 0·8975, n_D 1·4521, and forms a semicarbazone, m. p. 212°, oxime, m. p. 79—80° (benzoyl derivative, m. p. 69—70°), *isooxime*, m. p. 87—88°, hydrochlorobenzylidene derivative, m. p. 119—120°, and yields a mixture of menthols by reduction. The reduction of *i*-menthoneoxime yields *i*-menthylamine, b. p. 208°, which forms a hydrochloride, m. p. above 250°, carbamide, m. p. 151—152°, phenylmenthylcarbamide, m. p. 135—136°, phenylthiocarbamide, m. p. 136—137°, and benzylidene compound, m. p. 141—142°. C. S.

Pinacolin Transformation. II. Asymmetric Cyclic and Acyclic Pinacones and Their Transformation Products. HANS MEERWEIN (*Annalen*, 1913, **396**, 200—263. Compare A., 1910, i, 856).—A thorough examination of the reaction whereby 1-*iso*propyl*cyclo*pentane-1-α-diol is converted into 1 : 1-dimethyl*cyclo*hexan-2-one and of analogous reactions has led to the following important generalisations in connexion with the pinacolin transformation : (i) the pinacolin transformation is a true, intramolecular, atomic rearrangement ; intermediate products cannot be isolated ; (2) the course of the transformation is conditioned by different factors depending on the structure of the pinacone. In symmetric pinacones of the type $CRR'(OH) \cdot CRR' \cdot OH$, the transformation depends only on the relative ease of mobility of the groups R and R′, whilst in asymmetric pinacones, $CR_2(OH) \cdot CR'_2 \cdot OH$, the stability of the hydroxyl groups is the determining factor ; (3) by a study of the pinacolin transformation, it is possible, not only experimentally to ascertain the different stabilities (that is, the strength of their attachment to the carbon atoms) of the hydroxyl groups in asymmetric pinacones, but also, since such stability is determined mainly by the stabilities of the radicles attached to the same carbon atom, the relative strengths of the attachment of these radicles.

[With HANS PROBST.]—The interaction of methyl *cyclo*pentan-1-ol-1-carboxylate and an excess (4—5 mols.) of magnesium ethyl bromide or magnesium phenyl bromide leads by the usual method to the formation of 1-*hydroxy*-1-α-*ethylpropylcyclo*pentan-1-*ol*,

$$\begin{matrix} CH_2 \cdot CH_2 \\ CH_2 \cdot CH_2 \end{matrix} \!\!>\!\! C(OH) \cdot CEt_2 \cdot OH,$$
m. p. 39·5°, b. p. 136°/25 mm., and 1-α-*hydroxybenzhydrylcyclo*-pentan-1-*ol*, $\begin{matrix} CH_2 \cdot CH_2 \\ CH_2 \cdot CH_2 \end{matrix} \!\!>\!\! C(OH) \cdot CPh_2 \cdot OH$, m. p. 125°, colourless prisms, respectively. The former is converted by concentrated sulphuric acid at −10° into a mixture of 1 : 1-*diethylcyclo*hexan-2-*one*,

$$CH_2 \!<\!\! \begin{matrix} CH_2 - CO \\ CH_2 - CH_2 \end{matrix} \!\!>\!\! CEt_2,$$
b. p. 93·5°/15 mm., D^{20} 0·9236, n_D^{20} 1·4621 (the constitution of which is proved by its oxidation to αα-*diethyladipic acid*,

$$CO_2H \cdot CEt_2 \cdot CH_2 \cdot CH_2 \cdot CO_2H,$$
m. p. 90—92°, by nearly boiling 30% nitric acid), and 1-*propionyl*-1-*ethylcyclo*pentane, $\begin{matrix} CH_2 \cdot CH_2 \\ CH_2 \cdot CH_2 \end{matrix} \!\!>\!\! CEt \cdot COEt$, b. p. 86°/16 mm., D^{20} 0·9104, n_D^{20} 1·4525, which is oxidised to 1-*ethylcyclo*pentane-1-*carboxylic acid*,

m. p. − 8°, b. p. 132°/18 mm., by nearly boiling 40% nitric acid. The separation of the mixture is readily effected by means of the semicarbazones, the *semicarbazone*, m. p. 202—203°, rhombic leaflets, of the *cyclo*hexane derivative being sparingly soluble in alcohol or other solvents, whilst the *semicarbazone*, m. p. 148·5°, slender needles, of the *cyclo*pentane derivative is easily soluble.

The pinacolin transformation of 1-α-hydroxybenzhydryl*cyclo*pentan-1-ol by cold concentrated sulphuric acid yields only 1 : 1-*diphenylcyclohexan-2-one*, m. p. 99°, stout needles (*semicarbazone*, m. p. 240°), by the oxidation of which by chromic and acetic acids benzophenone is produced.

[With F. KREMERS.]—The product of the pinacolin transformation of 1-*iso*propyl*cyclo*hexane-1-α-diol contains about 33% of 1:1-*dimethylcycloheptan-2-one* (*semicarbazone*, m. p. 169°) in addition to the 1-acetyl-1-methyl*cyclo*hexane described by Tarbouriech.

1-α *Hydroxybenzhydrylcyclohexan-1-ol,*

$$CH_2 \underset{CH_2 \cdot CH_2}{\overset{CH_2 \cdot CH_2}{\diagup \diagdown}} C(OH) \cdot CPh_2 \cdot OH,$$
m. p. 130°, stout prisms, prepared from methyl*cyclo*hexan-1-ol-1-carboxylate and magnesium phenyl bromide, is transformed by concentrated sulphuric acid at 0° into the *ethylene oxide,*

$$CH_2 \underset{CH_2 \cdot CH_2}{\overset{CH_2 \cdot CH_2}{\diagup \diagdown}} C \underset{CPh_2}{\overset{O}{\diagup \diagdown}},$$
m. p. 92—94°, rhombic prisms, which does not react with semicarbazide and is oxidised to benzophenone, glutaric and adipic acids by chromic and acetic acids.

[With F. KREMERS and R. SPLITTEGARB.]—Ethyl 9-hydroxyfluorene-9-carboxylate reacts in the usual manner with an excess, 7—8 mols., of magnesium methyl iodide, magnesium ethyl bromide, or magnesium phenyl bromide to form, ultimately, 9-*β-hydroxyisopropylfluorenol,*

$$\underset{C_6H_4}{\overset{C_6H_4}{\diagdown \diagup}} C(OH) \cdot CMe_2 \cdot OH,$$ m. p. 101°, large, colourless needles,

9-*hydroxydiethylmethylfluorenol,* $\underset{C_6H_4}{\overset{C_6H_4}{\diagdown \diagup}} C(OH) \cdot CEt_2 \cdot OH,$ m. p. 106°,

colourless needles, and 9-α-*hydroxybenzhydrylfluorenol,*

$$\underset{C_6H_4}{\overset{C_6H_4}{\diagdown \diagup}} C(OH) \cdot CPh_2 \cdot OH,$$
m. p. 160—162°, slender needles, respectively. By cold concentrated sulphuric acid the first is transformed into 9-*acetyl-9-methylfluorene,* $\underset{C_6H_4}{\overset{C_6H_4}{\diagdown \diagup}} CMe \cdot COMe,$ m. p. 89°, b. p. 181°/18 mm. (*semicarbazone,* m. p. 254—256°), the second into 9-*propionyl-9-ethylfluorene,* m. p. 58° (*semicarbazone,* m. p. 236°), and the last, which is readily decomposed into benzophenone and fluorenol by 10% alcoholic potassium hydroxide, into 9 : 9-*diphenylphenanthrone,* $\underset{C_6H_4 \cdot CO}{\overset{C_6H_4 \cdot CPh_2}{| \quad |}}$, m. p. 197°, rhombic prisms.

The constitution of 9-acetyl-9-methylfluorene is proved by its decomposition into 9-methylfluorene and acetic acid by alcoholic potassium hydroxide, and by its oxidation to 9-*methylfluorene-9-carboxylic acid,*

m. p. 166°, glistening leaflets, by 10% sodium hypobromite. 9 : 9-Di-phenylphenanthrone is identical with the substance described as *s*-diphenyldiphenylene-ethylene oxide by Werner and Grob, but that it has the constitution denoted by its name is proved by the fact that it yields the acid, $CHPh_2 \cdot C_6H_4 \cdot C_6H_4 \cdot CO_2H$, by heating with alcoholic potassium hydroxide. Similarly, the pinacolins obtained by Zincke and Tropp from a series of pinacones prepared from phenanthra-quinone and magnesium alkyl haloids, and regarded by them as α-pinacolins (*s*-dialkyldiphenylene-ethylene oxides), are probably 9 : 9-di-alkylphenanthrones, since the methyl compound (9 : 9-dimethyl-phenanthrone), for example, is converted into 2-iso*propyldiphenyl-2'-carboxylic acid*, $CHMe_2 \cdot C_6H_4 \cdot C_6H_4 \cdot CO_2H$, m. p. 104—106°, by potassium hydroxide at 220—240°.

[With R. SPLITTEGARB.]—Acyclic, asymmetric pinacones have been prepared as similar as possible in structure to the preceding cyclic pinacones. Methyl α-hydroxy*iso*butyrate reacts with magnesium ethyl or phenyl bromide to form, ultimately, β-*methyl-γ-ethylamylene βγ-glycol*, $OH \cdot CMe_2 \cdot CEt_2 \cdot OH$, b. p. 99—101°/19 mm., and αα-*di-phenyl-β-methylpropylene glycol*, $OH \cdot CPh_2 \cdot CMe_2 \cdot OH$, m. p. 91°, respectively. βγ-*Dimethylamylene βγ-glycol*, $OH \cdot CMe_2 \cdot CMeEt \cdot OH$, b. p. 94—95°/21 mm., is prepared from *methyl methylethylglycollate*, b. p. 151·6—152° (the *ethyl* ester has b. p. 162°, and the *acid* itself has b. p. 133—134°/16 mm.), and magnesium methyl iodide.

β-Methyl-γ-ethylamylene βγ-glycol is transformed by concentrated sulphuric acid into *ethyl* tert.-*amyl ketone*, $CMe_2Et \cdot COEt$, b. p. 150·5—152°, D^{20} 0·8298 (*semicarbazone*, m. p. 98°), the constitution of which is proved by its oxidation to αα-dimethylbutyric acid by aqueous sodium hypobromite. By the pinacolin transformation, βγ-dimethylamylene βγ-glycol yields *methyl* tert.-*amyl ketone*,

$$CMe_2Et \cdot COMe,$$
b. p. 130 6°, D^{20} 0·8243 (*semicarbazone*, m. p. 136—138°), which also yields αα-dimethylbutyric acid by oxidation. αα-Diphenyl-β-methyl-propylene-αβ-glycol is transformed by cold concentrated sulphuric acid into methyl αα-diphenylethyl ketone, m. p. 41°, which is oxidised to αα-diphenylpropionic acid by sodium hypobromite.

[With F. KREMERS.]—*Bromodiphenylacetic acid*, $CPh_2Br \cdot CO_2H$, m. p. 133—134°, prepared from benzilic acid and hydrogen bromide in glacial acetic acid at 0°, is readily converted by methyl alcohol and sulphuric acid into methyl methoxydiphenylacetate, b. p. 191°/16 mm., m. p. 29°, which reacts with magnesium methyl iodide to form, ultimately, γ-*methoxy-γγ-diphenyl-β-methylpropane-β-ol*,

$$OMe \cdot CPh_2 \cdot CMe_2 \cdot OH,$$
m. p. 45—47°, b. p. 181—182°/16 mm.; the latter is converted by cold concentrated sulphuric acid into methyl αα-diphenylethyl ketone, not into ω-phenyl-ωω-dimethylacetophenone.

[By the AUTHOR.]—The various explanations of the pinacolin trans-formation are stated and criticised. The most widely accepted theory assumes the intermediate formation of ethylene oxides, but is not in agreement with observations of the author, Tiffeneau, Montagne, and others. The formation of tangible, intermediate products has not been observed, the transformation occurring by loss of water and the

migration of one group. The water must be eliminated before the migration occurs, because s- and as-diphenylmethylpropylene glycol yield the same pinacolin, $CPh_2Me\cdot COMe$, and s- and as-dimethyldiethylethylene glycol also produce the same pinacolin, $CMe_2Et\cdot COEt$. If these changes are explained by an interchange in position of a hydroxyl and an alkyl or aryl group and subsequent elimination of water, the author claims that sometimes one group, sometimes another, changes position with the hydroxyl group without any regularity or obvious reason.

The first step in the transformation, therefore, is

$$OH\cdot CR_2\cdot CR_2\cdot OH \longrightarrow \cdot CR_2\cdot CR_2\cdot O\cdot.$$
The complex then changes to a stable state, either $O{<}{\small\begin{matrix}CR_2\\[-2pt] |\\[-2pt] CR_2\end{matrix}}$, which

is quite exceptional, or $CR_3\cdot COR$. Symmetric pinacones,

$$OH\cdot CRR'\cdot CRR'\cdot OH,$$
contain hydroxyl groups of like function, and therefore yield, by loss of water, the complex $\cdot CRR'\cdot CRR'\cdot O\cdot$. The final state of this complex depends on the relative mobilities of R and R'; in general, the methyl group migrates more readily than its homologues, aliphatic groups less readily than aromatic, and substituted aromatic groups more readily than the phenyl radicle. In asymmetric pinacones, $OH\cdot CR_2\cdot CR'_2\cdot OH$, the hydroxyl groups are not of similar function, and, therefore, the first step of the pinacolin transformation may be the formation of $\cdot CR_2\cdot CR'_2\cdot O\cdot$ or $\cdot CR'_2\cdot CR_2\cdot O\cdot$ or both, the actual course being determined by the relative stabilities of the two hydroxyl groups. When the stabilities are about equal, two products are obtained, as, for example, 1 : 1-diethyl*cyclo*hexan-2-one and 1-propionyl-1-ethyl*cyclo*pentane from 1-hydroxydiethylmethyl*cyclo*pentan-1-ol. Hitherto, nothing has been known of the influence of alkyl groups on the stability of hydroxyl groups; since as-dimethyldiethylethylene glycol is transformed into ethyl tert.-amyl ketone, it appears that the hydroxyl group in the neighbourhood of the heavier alkyl group has the greater stability.   C. S.

Syntheses by means of Sodamide. ALBIN HALLER and ÉDOUARD BAUER (*Ann. Chim. Phys.*, 1913, [viii], **28**, 373—414).— A résumé of information on this subject, referring principally to the results recorded in the following Abstracts: 1909, i, 108, 654; 1911, i, 726, and 1912, i, 270.   T. A. H.

A Fourth Modification of Benzophenone. WALTER A. WAHL (*Chem. Zentr.*, 1913, i, 813—814; from *Öfvers. Finska Vetens. Soc. Förhandl.*, 1911, **54**, *A*, 10. Compare A., 1912, ii, 1044).—When benzophenone is melted in a narrow, thin-walled glass tube at 50°, and then plunged into a carbon dioxide-ether mixture, a vitreous mass, is obtained which develops spherulitic groups of fibrous crystals at $-60°$ to $-65°$ which melt at $-51°$. Tammann observed that the speed of crystallisation of stable benzophenone (I) below $-40°$ is so small that this form cannot be produced at such low temperatures at all. The new labile modification (IV) can therefore melt without

passing into the stable form. The other modifications are Tammann's (II) with m. p. 45—48° and Zincke's (III), m. p. 26°.   J. C. W.

Anthracene. III. Derivatives of Anthrone. KURT H. MEYER and ALBERT SANDER (*Annalen*, 1913, **396**, 133—151).—The influence of substituents in position 9 on the desmotropy of anthrone has been further examined. Anthrone itself, even in solution, exists chiefly in the ketonic modification; anthraquinol and its methyl ether, however, are mainly enolic.

On account of its non-fluorescence, insolubility in cold alkalis, and indifference to alcoholic bromine, 9-phenylanthrone exists in the ketonic form. By solution in hot alkali and precipitation by acid in the cold, it is obtained in the form of 9-*phenylanthranol*,

$$C_6H_4 {<}^{C(OH)}_{CPh}{>} C_6H_4,$$
which is sulphur-yellow and yields intensely fluorescent solutions; by keeping or by crystallisation, the anthranol reverts to the anthrone.

The equilibrium of the two modifications of this substance (and also of the following substances) in solution has been determined as follows. An alcoholic solution, about 0·1%, at the ordinary temperature is intensely illuminated by an iron arc and is titrated with $N/10$-alcoholic bromine. Since only the enolic form reacts with bromine and is fluorescent, the disappearance of the fluorescence furnishes a sharp endpoint. The same result is attained by starting with the anthrone or the anthranol, provided that the solution has been kept for a sufficiently long time. By this method it is shown that glacial acetic acid favours the formation of the ketonic modification, that all anthrone derivatives are immediately converted into anthranols by pyridine, that equilibrium is not attained in benzene or chloroform even after prolonged boiling, and that the velocity of transformation in alcohol is very much increased by the addition of concentrated hydrochloric acid and, still more, of sodium acetate.

9-Nitroanthrone, which is readily obtained by the nitration of anthrone in glacial acetic acid by nitric acid, D 1·5, at 60°, is converted into 9-nitroanthranol (Meisenheimer's *aci*-nitroanthrone) by solution in hot alkali and precipitation in the cold by acids. After equilibrium has been established in alcohol, the solution contains 97% of the ketonic form. The end-point is readily detected, since 9-nitroanthranol is yellow, and 9-nitroanthrone is colourless, in solution. 9-Nitroanthrone is converted into 9-*nitroanthranyl acetate*,

$$C_6H_4 {<}^{C(OAc)}_{C(NO_2)}{>} C_6H_4,$$
m. p. 182°, citron-yellow leaflets or needles, by acetyl chloride in cold pyridine, and into 9-*nitroanthranyl benzoate*, m. p. 238° (decomp.), amber-yellow prisms, by benzoyl chloride and pyridine on the water-bath.

9-*Anilinoanthrone*, $C_6H_4 {<}^{CO}_{CH(NHPh)}{>} C_6H_4$, m. p. 154—156°, reddening at 146°, faintly yellow needles, prepared from 9-bromo-anthrone and aniline in boiling benzene, is converted by treatment
with alcoholic potassium hydroxide and subsequent acidification into 9-*anilinoanthranol*, $C_6H_4\diagdown\diagup\begin{smallmatrix}C(OH)\\C(NHPh)\end{smallmatrix}\diagup\diagdown C_6H_4$, m. p. 155°, reddish-brown crystals, which forms orange-red solutions with intense yellowish-green fluorescence. The alcoholic solution, after several days, contains about 80% of the anthranol. Both forms are converted into anthra-quinol and aniline by boiling dilute acids and alcohol. 9-Anilino-anthrone is converted into 9 *aniloanthrone*, $C_6H_4\diagdown\diagup\begin{smallmatrix}CO\\C(:NPh)\end{smallmatrix}\diagup\diagdown C_6H_4$, m. p. 123—124°, red needles, by alcoholic potassium hydroxide and potassium ferricyanide, and into 9-*anilinoanthranyl benzoate*,

$$C_6H_4\diagdown\diagup\begin{smallmatrix}C(OBz)\\C(NHPh)\end{smallmatrix}\diagup\diagdown C_6H_4,$$
m. p. 226°, yellow crystals, by benzoyl chloride and cold pyridine.

9-β-*Naphthylaminoanthrone*, m. p. 179—180°, yellow needles, 9-β-*naphthylaminoanthranol*, m. p. 187—188°, bluish-black needles, and 9-β-*naphthyliminoanthrone*, m. p. 167—168°, dark red crystals, are prepared by methods similar to the preceding.

With the object of preparing 9-aminoanthrone, a cold solution of 9-bromoanthrone in dry benzene was saturated with ammonia. The product, however, is 9-*bromodianthrone*,

$$CO\diagdown\diagup\begin{smallmatrix}C_6H_4\\C_6H_4\end{smallmatrix}\diagup\diagdown CBr\cdot CH\diagdown\diagup\begin{smallmatrix}C_6H_4\\C_6H_4\end{smallmatrix}\diagup\diagdown CO,$$

amber crystals, which, above its m. p., 187°, or by boiling with xylene and copper powder, is converted into dianthrone. 9-Aminoanthrone in a very impure state is produced by reducing benzeneazoanthranol with zinc dust and alcoholic sodium hydroxide in an atmosphere of nitrogen.   C. S.

Experiments on the Determination of the Constitution of Enolic Substances. JOHANNES SCHEIBER and PAUL HEROLD (*Ber.*, 1913, **46**, 1105—1110).—The authors have attempted to apply the use of ozone and subsequent decomposition of the ozonide formed for the determination of the constitution of enolic substances. The advantages claimed for the method are that operations can be carried out at low temperatures and that the addition of ozone, as far as is yet known, takes place without previous structural alteration of the substances investigated.

A solution of benzoylacetone in chloroform was treated with ozone and the ozonide subsequently decomposed by warm water. The cooled solution deposited an almost quantitative amount of benzoic acid, whilst the filtrate, when treated with phenylhydrazine, yielded methyl-glyoxalosazone, m. p. 146° (Harries and Turk, A., 1905, i, 413, give 145°). Neither acetic acid nor carbon dioxide could be detected. Benzoylacetone appears therefore to be enolised according to the formula $OH\cdot CPh:CH\cdot COMe$, which confirms the work of Smedley (T., 1910, **97**, 1486).

Oxalacetone, when similarly treated, gave a 93·5% yield of oxalic acid, from which it follows that enolisation must also have occurred to some extent towards the acetyl group. Although acetic acid could not

be detected, this is confirmed by the fact that phenylhydrazine did not yield pure methylglyoxalosazone.

The ozonide obtained in small quantity from ethyl acetoacetate, when decomposed by water, yielded with phenylhydrazine acetate a precipitate of pure ethyl phenylhydrazonoglyoxylate,

$$NHPh\cdot N\colon CH\cdot CO_2Et,$$

m. p. 128° (Reissert, A., 1895, i, 461, gives 129°; v. Pechmann, 1896, i, 678, finds 130—131°), from which the formula $OH\cdot CMe\colon CH\cdot CO_2Et$ is deduced for the enolised ester.

Ethyl benzoylacetoacetate under similar treatment gave rise to benzoic acid and to the somewhat impure osazone of ethyl diketobutyrate, $CMe(N_2HPh)\cdot C(N_2HPh)\cdot CO_2Et$. Although the benzoic acid formed has not yet been estimated, the enolised form of ethyl benzoylacetoacetate must possess mainly the configuration

$$OH\cdot CPh\colon C(COMe)\cdot CO_2Et.$$
Diacetylbenzoylmethane, m. p. 34°, similarly yielded benzoic acid mixed•with small quantities of a substance which could not be identified with certainty, whilst, after removal of benzoic acid, the bisphenyl-hydrazone of triketopentane, m. p. 155° (Sachs and Barschall, A., 1901, i, 670, give 156°), was isolated by means of phenylhydrazine. The authors conclude that the enolised form of diacetylbenzoylmethane consists mainly of the α-form, $CPh(OH){=}C{<}^{COCH_3}_{COCH_3}$, probably mixed with small amounts of the β-variety, $CMe(OH){=}C{<}^{COCH_3}_{CO\cdot C_6H_5}.$

H. W.

Phthalylglycyl Derivatives of Acetylacetone, Benzoylacetone, and Ethyl Cyanoacetate. JOHANNES SCHEIBER [with K. KLOPPE and K. SCHNABEL] (*Ber.*, 1913, 46, 1100—1105).—The author has extended his work on the condensation of ethyl sodioacetoacetate with phthalylglycyl chloride (A., 1909, i, 390).
The sodium derivative of acetylacetone reacts readily with phthalyl-glycyl chloride in the presence of ether or benzene. The main product of the reaction is *bisphthalylgylcylcylacetylacetone*, smaller quantities of *C-phthalylglycylacetylacetone* and *o-phthalylglycylacetylacetone* being also formed. The latter substance is, however, mainly formed when the silver derivative of acetylacetone is substituted for the sodium derivative. If the reaction is carried out in boiling benzene solution, *phthalylglycyl anhydride* is also obtained.

Bisphthalylglycylacetylacetone,

$$C_6H_4{<}^{CO}_{CO}{>}N\cdot CH_2\cdot CO\cdot O\cdot CMe\colon C(COMe)\cdot CO\cdot CH_2\cdot N{<}^{CO}_{CO}{>}C_6H_4,$$
has a variable m. p., probably due to partial enolisation. Thus, a product, m. p. 182° (highest observed m. p.), after recrystallisation from glacial acetic acid had m. p. 168°. Cold sodium ethoxide converts it into *C*-phthalylglycylacetylacetone. With aniline it yields *phthalylglycyl-acetylacetone anilide*, $C_6H_4\colon(CO)_2\colon N\cdot CH_2\cdot CO\cdot C(COMe)\colon CMe\cdot NHPh$, yellow needles, m. p. 172°. Phenylhydrazine converts it into *phthalyl-glycylacetylacetonepyrazolephenylhydrazone* (formula I or II), lemon-yellow leaflets, m. p. 192°, the same substance being obtained from the

above anilide or from C-phthalylglycylacetylacetone. It is not decomposed by sodium hydroxide, does not reduce Fehling's solution, and gives a blue coloration with ferric chloride when dissolved in concentrated sulphuric acid.

$$C_6H_4{:}(CO)_2{:}N{\cdot}CH_2{\cdot}C(N_2HPh){\cdot}C{<}^{OMe=\!\!N}_{OMe-\!\!NPh}{\cdot}$$

(I.)

$$NPh{<}^{OMe{:}C{\cdot}OMe{:}N_2HPh}_{N=\!\!\!=\!\!C{\cdot}CH_2{\cdot}N{:}(CO)_2{:}C_6H_4}{\cdot}$$

(II.)

C-Phthalylglycylacetylacetone, m. p. 124°, is soluble in aqueous sodium hydroxide without decomposition, and gives an immediate blood-red coloration with alcoholic ferric chloride.

O-Phthalylglycylacetylacetone, m. p. 107°, is insoluble in aqueous sodium hydroxide, and yields a red coloration with ferric chloride after some time. It is decomposed by a solution of phenylhydrazine in glacial acetic acid with formation of *phthalylglycylphenylhydrazide*, $C_6H_4{:}(CO)_2{:}N{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}NHPh$, m. p. 192°, which was also prepared from phthalylglycyl chloride and phenylhydrazine. When, however, the free acid was heated with phenylhydrazine in dilute acetic acid solution, the main product was anilinophthalimide, $C_6H_4{:}(CO)_2{:}N{\cdot}NHPh$, m. p. 179°.

Phthalylglycyl anhydride, $C_{20}H_{12}O_7N_2$, white needles, m. p. 242°, is transformed by phenylhydrazine into phthalylglycylphenylhydrazide, and by aniline into phthalylglycylanilide, m. p. 231—232°. The latter substance was also obtained from phthalylglycyl chloride and aniline.

The action of phthalylglycyl chloride on the sodium derivative of benzoylacetone yields *bisphthalylglycylbenzoylacetone* and O-*phthalylglycylbenzoylacetone*. The former, m. p. 151°, gradually gives a red coloration with ferric chloride in alcoholic solution, and is converted by cold sodium alkoxide into O-*phthalylglycylbenzoylacetone*, m. p. 135°. The latter immediately gives an intense red coloration with ferric chloride.

O-Phthalylglycylbenzoylacetone, m. p. 147—148°, gives no coloration with ferric chloride, and is insoluble in sodium hydroxide. Phenylhydrazine eliminates the phthalylglycyl radicle.

With ethyl sodiocyanoacetate, phthalylglycyl chloride yields practically solely *ethyl phthalylglycylcyanoacetate*, long needles, m. p. 149°. The ester is immediately soluble in alkali and alkali carbonate solutions, and gives an immediate intense red coloration with ferric chloride. An alcoholic solution of phenylhydrazine converts it into phthalylglycylphenylhydrazide. In glacial acetic acid solution at the ordinary temperature, however, phenylhydrazine converts it into a *substance*, $C_{21}H_{20}O_5N_4$, m. p. 156°, which is probably an additive product. It is soluble in sodium hydroxide, does not give Bülow's reaction, and reduces Fehling's solution in the cold. Concentrated sulphuric acid regenerates the ester.   H. W.

Action of Hydrochloric Acid on p-Benzoquinonesulphonic Acid. ALPHONSE SEYEWETZ (*Compt. rend.*, 1913, **156**, 901—903).— Concentrated hydrochloric acid acting on sodium p-benzoquinone-

sulphonate at temperatures below 20° yields after twelve hours a crystalline mass of *sodium chloroquinolsulphonate*, $C_6H_2Cl(OH)_2 \cdot SO_3Na$, white needles, soluble in water, instantly reducing silver nitrate. On oxidation it is converted into chloro-*p*-benzoquinonesulphonic acid.

If the reaction takes place at above 20°, the products are chloroquinol and 2 : 6-dichloroquinol. W. G.

Action of Nitrous Acid on Dianilino-*p*-benzoquinoneanil. CONSTANTIN I. ISTRATI and M. A. MIHAILESCU (*Bull. Acad. Sci. Roumaine*, 1912/3, 1, 25—29. Compare Istrati, A., 1903, i, 82).—When an excess of sodium nitrite is added to a solution of dianilino-*p*-benzoquinoneanil in cold glacial acetic acid, a number of *products* are obtained, of which three, m. p. 209°, 248° and 286° respectively, have been isolated. The first of these separates from toluene in brilliant red leaflets. It is not attacked by boiling solutions of alkali hydroxides. It dissolves in concentrated sulphuric acid and in fuming nitric acid, but is precipitated unchanged when these solutions are diluted with water. It gives Liebermann's reaction, but the presence of a nitro-group could not be established. The formula,

$$\text{NO·NPh·C} {\overset{\text{CH}——\text{CO}}{\underset{\text{C(NPh)·CH}}{\bigg\langle}}} \text{C·N:C} {\overset{\text{CH:CH}}{\underset{\text{CH:CH}}{\bigg\langle}}} \text{CO},$$

is assigned to it, the dinitrosoamine first formed undergoing partial rearrangement with the formation of the oxime of a substituted *p*-benzoquinoneimide, from which the *p*-benzoquinone is formed by elimination of hydroxylamine. H. W.

Metaquinonoids. RICHARD MEYER (*Ber.*, 1913, 46, 1220).— Stark and Garben (this vol., i, 361) relying on the earlier work of Meyer and Desamari (A., 1908, i, 658) included Liebermann and Dittler's tribromoresoquinone as a substance of metaquinonoid type. Later experiments of these authors, however, had already shown that the compound was a bimolecular keto-bromide, $C_{12}H_2O_4Br_6$ (A., 1909, i, 241, 657). J. C. W.

Preparation of Anthraquinone from Anthracene. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 256623).—Anthraquinone is obtained in 94—96% yield when an intimate mixture of anthracene, glass wool, or asbestos powder, and a metal or metallic oxide (such as zinc dust or lead oxide) is carefully treated with nitric acid fumes at 75—100° for about nine hours; the temperature is then slowly raised to 280°, when the anthraquinone sublimes in long, yellow needles. F. M. G. M.

Preparation of Chlorinated Anthraquinones and Anthracenes. H. SCHILLING (*Ber.*, 1913, 46, 1066—1069).—Starting from 1- and 2-chloroanthraquinone and from 1 : 5- and 1 : 8-dichloroanthraquinone, the author has prepared a number of the higher chlorinated anthraquinones by converting them into the corresponding chloroanthraquinonesulphonic acids and replacing the sulphonic acid with chlorine by treatment of the potassium salts of the sulphonic acids with chlorine in aqueous solution at 100°. The sulphonation

was carried out by heating the chloroanthraquinones with sulphuric acid containing 20% of anhydride for four hours at 150—160°, both alone and in the presence of mercurous sulphate. Although the position of the sulphonic acid groups has not been definitely established, it is assumed from the results of Schmidt (A., 1904, i, 256) and Iljinsky (A., 1904, i, 176) that in the presence of the mercurous salt the sulphonic acid group takes up the α-position, whilst if no catalyst is employed the group enters the β-position.

With sulphuric acid alone monosulphonic acids are obtained. In the presence of mercurous sulphate 1-chloro- and the two dichloroanthraquinones yield disulphonic acids, whilst 2-chloroanthraquinone forms a monosulphonic acid. In addition to the disulphonic acid the 1:5-dichloro-compound also yields a monosulphonic acid.

The potassium salts of the chloroanthraquinonesulphonic acids are colourless or pale yellow, and are sparingly soluble in water.

The chloroanthraquinones are converted by reduction with zinc dust and ammonia into the corresponding chloroanthracenes, of which the monochloro-compounds form colourless, strongly, fluorescent leaflets or needles, whereas the di-, tri-, and tetra-chloro-derivatives crystallise in yellow needles.

In the following, (a) denotes sulphonation in the absence, (b) in the presence, of mercurous sulphate.

1-Chloroanthraquinone yields (a) 1-*chloroanthraquinonesulphonic acid* and (b) 1-*chloroanthraquinone-αα-disulphonic acid*; αβ-*dichloro*- (m. p. 166—168°) and ααα-*trichloro-anthraquinones*, m. p. 165—168°, which are reduced to αβ-*dichloro*- (m. p. 130—135°) and ααα-*trichloroanthracene* (m. p. 133—135°).

2-Chloroanthraquinone gives rise to (a) 2-*chloroanthraquinone-β*- and (b) -α-*sulphonic acids*; ββ- and αβ-*dichloroanthraquinones* have m. p. 284—285° and 278—280° respectively, and yield ββ- and αβ-*dichloroanthracenes*, m. p. 216° and 155—160°.

1:5-Dichloroanthraquinone gives rise to (a) 1:5-*dichloroanthraquinone-β-sulphonic acid* and (b) 1:5-*dichloroanthraquinone-α-sulphonic* and -αα-*disulphonic acids*; 1:5-β- (m. p. 230—235°) and 1:5-α-*trichloroanthraquinone*, m. p. 256°, and 1:5:4:8-*tetrachloroanthraquinone*, m. p. 339°; 1:5-β-*trichloroanthracene* has m. p. 170—175°, the 1:5:4:8-*tetrachloro*-compound, m. p. 275° or 285—286°, and the 1:5:α-*trichloro*-compound, m. p. 270—275°.

1:8-Dichloroanthracene yields (a) 1:8-*dichloroanthraquinone-β-sulphonic acid* and 1:8-*dichloroanthraquinone-αα-disulphonic acid*; 1:8:β-*trichloroanthraquinone*, m. p. 295—300°, and 1:8:β-*trichloroanthracene*, m. p. 185—190°.

1-*Chloroanthracene* has m. p. 81—82°, 2-*chloroanthracene*, m. p. 215°, 1:5-*dichloroanthracene*, m. p. 185°, and 1:8-*dichloroanthracene*, m. p. 156°.

Preparation of Selenocyanates of the Anthraquinone Series.

FARBENFABRIKEN VORM FRIEDR. BAYER & Co (D.R.-P. 256667).—When the anthraquinone diazoselenocyanates are carefully heated (preferably in the presence of copper or cuprous salts) nitrogen

is eliminated and the selenocyanate group enters the ring :
$$C_{14}H_7O_2 \cdot N_2 \cdot SeCN = N_2 + C_{14}H_7O_2 \cdot SeCN.$$
1-*Selenocyanoanthraquinone*, yellowish-red needles, m. p. 249°, is obtained when aminoanthraquinone (2·2 parts) is diazotised in concentrated sulphuric acid with nitrosyl sulphate, ice added, and the precipitated diazonium sulphate collected, dissolved in water, and treated with an aqueous solution of potassium selenocyanate (1·5 parts); the precipitated red *diazoanthraquinone selenocyanate* when warmed is converted into 1-selenocyanoanthraquinone, which is purified by crystallisation from nitrobenzene. *Potassium 1-selenocyanoanthraquinone-5-sulphonate* is prepared in a similar manner from sodium 1-aminoanthraquinone-5-sulphonate.　　　　　　　　　　　　　F. M. G. M.

Preparation of 2-Anthraquinone Sulphide. Irma Ullmann-Goldberg (D.R.-P. 255591).—2-*Dianthraquinonyl sulphide*, orange-yellow prisms, m. p. 275—276°, is obtained when 2-chloroanthraquinone is boiled for six hours with an equal weight of potassium xanthate and 10 parts of amyl alcohol.　　　　　　　　　F. M. G. M.

Action of Colloidal Metallic Hydroxides on Hydroxyanthraquinones. R. Haller (*Farber-Zeit.*, 1912, **23**, 489—492, 523—528).—A description of the preparation of colloidal solutions of aluminium, chromium, and ferric hydroxides, and of the complex salts : $Al_2(SO_4)_2(OH)_2$, $Al_2(SO_4)_3(OAc)_3$, $Al_2(SO_4)(OAc)_4$,
$$Al_2(SO_4)(OH)_2(OAc)_2,$$
$Al_2(OAc)_6$, $Al_2(OAc)_4(OH)_2$, and $Al_2(OAc)_2(OH)_4$; these were combined with alizarin, purpurin, anthrapurpurin, flavopurpurin, and alizarin-orange, and the physical and chemical properties of the *compounds* so obtained are comparatively tabulated with the normal iron, aluminium, and chromium salts.

The following properties were studied, absorption spectra, together with their behaviour in the presence of hydrochloric acid, ammonium hydroxide, calcium chloride, sodium chloride, sodium hydrogen phosphate, and absolute alcohol.　　　　　　　　　　　　F. M. G. M.

Bupleurol or Dihydronerol Constitution. II. Luigi Francesconi and E. Sernagiotto (*Atti R. Accad. Lincei*, 1913, [v], **22**, i, 148—154. Compare this vol., i, 283).—Reasons are advanced showing that bupleurol probably has the structure : $CHMe_2 \cdot [CH_2]_3 \cdot C(:CH_2) \cdot CH_2 \cdot CH_2 \cdot OH.$　　　　R. V. S.

The Autoxidation of Turpentine. Arnold Blumann and Otto Zeitschel (*Ber.*, 1913, **46**, 1178—1198).—On distilling a resinified Grecian turpentine in steam, the less volatile portions were found to respond to tests for aldehydes (compare Schiff, A., 1883, 1141). An oil, $C_{10}H_{14}O$, was obtained on fractionation, but it was stable towards alkalis, did not readily yield an acid on oxidation, or a secondary alcohol with the Grignard reagent, neither would it undergo condensations. It was therefore considered to be a ketone with pseudo-aldehydic properties, like Wallach's *iso*propyl-Δ^2-hexenone (A., 1908, i, 425). Further investigations showed that it was unsaturated, and that it gave a saturated secondary alcohol with sodium

and moist ether, and a saturated ketone by Paal's reduction. It was completely identified with Kerschbaum's verbenone (A., 1900, i, 353), and its constitution was established, the chief evidence being that it gave pinononic acid on oxidation with permanganate (experiments by F. MEISTER), and that hydrolysis with dilute sulphuric acid resulted in the formation of acetone and a methyl*cyclo*hexenone, which gave γ-acetobutyric acid on oxidation.

3-Methyl*cyclo*-Δ²-hexene-1-one.   γ-Acetobutyric acid.

Its rotation was stated by Kerschbaum to be + 66°, but it is really more by 180°. The *l*-modification was also obtained from French turpentine. Besides verbenone, the crude product contained alcoholic substances, evidence of the existence of verbenol being obtained, although the substance could not be completely purified.

The fact that the unsaturated linking of pinene is preserved after autoxidation seems contradictory, but it is assumed that the addition of water at this point precedes oxidation, and that after the latter process has occurred at the neighbouring –CH₂-group, the water is again eliminated.

From 900 grams of the less volatile constituents of Grecian turpentine which had been exposed to air for six months, 146 grams were collected at 105—107°/5 mm. *d*-Verbenone, $C_{10}H_{14}O$, was separated from this by a neutral sulphite solution with sodium hydrogen carbonate (compare Tiemann, A., 1899, i, 247), or as the semicarbazone, in the form of a colourless oil, which soon became yellow in the light. It had b. p. 227—228°, or 100°/16 mm., m. p. 6·5°, D^{15} 0·981, D^{20} 0·9780 $[a]_D$ + 249·62°, $[a]_D$ in alcohol + 229·60°, $[a]_D$ in benzene + 245·70°, n_D^{18} 1·49928. It formed an *oxime*, $C_{10}H_{14}\cdot NOH$, m. p. 115°, was scarcely affected by hydrogen chloride in carbon disulphide or ether, or by acetic anhydride, but it absorbed hydrogen chloride with partial decomposition in glacial acetic acid. On reduction with sodium in moist ether, it yielded *dihydro*-d-*verbenol*, $C_{10}H_{18}O$, in silky needles with the celery-like smell of verbenone, m. p. 58°, b. p. 218°, a_D + 1°30′ (10% alcoholic solution). The *acetate*, D^{15} 0·9926, a_D – 0·50° (25 mm.), and the *phthalate*, $C_{18}H_{22}O_4$, m. p. 127—129°, were prepared. On

oxidation it yielded *dihydro-d-verbenone*, $C_{10}H_{16}O$, which was also obtained by reduction of verbenone with colloidal palladium and hydrogen as an oil, b. p. 222°, D^{15} 0·9685, D^{18} 0·966, D^{20} 0·9642, $[a]_D$ +52·19°, n_D 1·47535. The *semicarbazone*, m. p. 220—221°, the *oxime*, m. p. 77—78°, and the *benzylidene* compound, m. p. 152—153°, or 103—104° after three months, were obtained. Verbenone was also treated with magnesium methiodide, when the lowest fraction of the product was found to be an inactive hydrocarbon, *methylverbenene*, $C_{11}H_{16}$. The pure substance had b. p. 49°/8 mm., 175—176°/771 mm., D^{15} 0·876, D^{20} 0·872, n_D^{20} 1·4969.

One kilogram of French turpentine was also exposed to air for three months, and 370 grams of less volatile products were fractionated, yielding 41·5 grams at 90—100°/12 mm. By means of neutral sulphite, 18 grams of l-*verbenone* were obtained, having a lower rotation than the isomeride, $[a]_D$ – 126·84°, D^{15} 0 980, n_D 1·4994, and forming a *semicarbazone*, m. p. 185—190°. The semicarbazone from inactive verbenone had m. p. 180—181°.

The alcohol present in the residue which remained after shaking the high fraction with sulphite was isolated by means of benzoyl chloride in pyridine. The benzoate, D^{15} 1·048, gave an oil on hydrolysis, which solidified in a freezing mixture to a mass of large leaflets. After pressing out the impurities the purified d-*verbenol*, $C_{10}H_{16}O$, had the constants, b. p. 216—218°, with elimination of water, D^{15} 0·9742, D^{18} 0 9722, D^{20} 0·9702, $[a]_D$ +132·30°, n_D^{20} 1·4890. No solid derivatives could be obtained, but the alcohol gave verbenone with chromic acid, and pinononic acid with permanganate. When the crude or pure substance was heated with acetic anhydride, water was easily removed and l-*verbenene*, $C_{10}H_{14}$, was obtained, b. p. 159—160°, D^{15} 0·8852, D^{20} 0·8822, a_D^{19} – 74·90° (100 mm.), n_D^{20} 1·49855. On the other hand, phosphoric oxide or zinc chloride yielded a hydrocarbon which was proved to be p-cymene, since it gave p-hydroxyisopropylbenzoic acid on warming with permanganate. The residue from l-verbenone was treated as above, but, although l-verbenol was found, it was still more difficult to purify it.   J. C. W.

Synthetic β-Glucosides of the Terpene Alcohols. JULIO HAMALAINEN (*Biochem. Zeitsch.*, 1913, **49**, 398—412).—The alcohols were shaken in ethereal solution with acetobromoglucose and silver carbonate, which were added in portions alternately. The glucosides were then obtained from the acetyl compounds thus produced by hydrolysis with barium hydroxide. The following substances were obtained: d-*Citronellol-tetra-acetyl*-d-*glucoside*, $C_{24}H_{88}O_{11}$, m. p. 30° (corr.), white needles from dilute alcohol. d-*Citronellol*-d-*glucoside*, $C_{16}H_{80}O_6$, a viscid syrup, with $[a]_D^{20}$ – 28·59°; it is hydrolysed by emulsin. cyclo*Hexanol-tetra-acetyl*-d-*glucoside*, $C_{20}H_{80}O_{10}$, m. p. 119—120° (corr.), and cyclo*hexanol*-d-*glucoside*, $C_{12}H_{22}O_6$, m. p. 133—135° (corr.) (without water of crystallisation), with $[a]_D^{20}$ – 42·52°. The substance with water of crystallisation has m. p. 128·5—129·5° (corr.); it is not very readily hydrolysed with emulsin. *Terpineol-32°-tetra-acetyl*-d-*glucoside*, $C_{24}H_{36}O_{10}$, m. p. 114—116°. *Terpineol-32°*-d-*glucoside*, $C_{16}H_{28}O_6$, sinters at 50°, m. p. 90°, with $[a]_D^{20}$ – 10·94° when

anhydrous, and has a bitter taste. The form with $1H_2O$ has m. p. 80·5—82·5° (corr.). The glucoside is not readily hydrolysed by emulsin. *Terpineol*-35°-*tetra-acetyl*-d-*glucoside*, $C_{24}H_{86}O_{10}$, m. p. 130—132° (corr.). *Terpineol*-35°-d-*glucoside*, $C_{16}H_{28}O_6$, sinters at 100°, m. p. 110° (water free), with $[a]_D^{20} - 5·88°$; it has a bitter taste; with water of crystallisation it melts at 106—108° (corr.); it is slowly hydrolysed by emulsin. d-*Dihydrocarveol-tetra-acetyl*-d-*glucoside*, $C_{24}H_{86}O_{10}$, m. p. 155—156° (corr.). d-*Dihydrocarveol*-d *glucoside*, $C_{16}H_{28}O_6$, m. p. (with water of crystallisation) 164—165° (corr.), with $[a]_D^{20} + 36·52°$. It is only sparingly soluble in water, and is hydrolysed readily by emulsin. cis-*Terpin-tetra-acetyl*-d-*monoglucoside*, $C_{24}H_{88}O_{11}$, m. p. 129—139° (corr.). cis-*Terpin*-d-*monoglucoside*, $C_{16}H_{80}O_7, H_2O$, m. p. 143—149° (corr.), with $[a]_D^{20} - 11·09°$, is not readily hydrolysed by emulsin.   S. B. S.

Synthesis of Alkyl Glucosides by means of Emulsin, β-Phenylethyl Glucoside, and β-Cinnamyl Glucoside. ÉMILE BOURQUELOT and MARC BRIDEL (*Compt. rend.*, 1913, 156, 827—829; *J. Pharm. Chim.*, 1913, [vii], 7, 335—340).—The authors have prepared two other glucosides by their usual method (compare A., 1912, i, 672).

β-*Phenylethyl glucoside*, $C_6H_{11}O_6 \cdot CH_2 \cdot CH_2Ph$, crystallises in colourless needles, having a bitter taste. It has $[a]_D - 23·92°$, and reduces Fehling's solution.

β-*Cinnamyl glucoside*, $C_6H_{11}O_6 \cdot CH_2 \cdot CH:CHPh$, crystallises in colourless needles, $[a]_D - 41·12°$, and having only a slight reducing action. Both of these glucosides are readily hydrolysed by emulsin in aqueous solution.   W. G.

Synthesis of Alkyl Galactosides by means of Emulsin. β-Methyl Galactoside and β-Allyl Galactoside. ÉMILE BOUR-QUELOT and MARC BRIDEL (*Compt. rend*, 1913, 156, 1104—1106[*]).—The two galactosides were prepared in the usual way by the action of emulsin on solutions of galactose in the respective alcohols. After evaporating off the excess of alcohol under reduced pressure, the unaltered galactose was destroyed by fermentation with bottom yeast in the presence of dextrose.

β-*Allyl galactoside* crystallises in colorless needles, $[a]_D - 12·5°$, and, like the methyl galactoside, it is readily hydrolysed by emulsin in aqueous solution.   W. G.

Rhamnoxanthin from Rhamnus cathartica and Frangulin from Rhamnus frangula. N. KRASOVSKI (*J. Russ. Phys. Chem. Soc.*, 1913, 45, 188—193. Compare A., 1909, ii, 174).—Examination of the two glucosides, rhamnoxanthin, and frangulin, and of their derivatives and products of hydrolysis indicates their identity. The name frangulin is suggested for retention.   T. H. P.

Preparation of the Active Principle of Apocynum. FAR-BENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 255537. Compare T., 1909, 95, 734).—The boiling carbon tetrachloride extract of the rhizome of *Apocynum cannabinum* furnished a *compound*, glistening prisms, m. p. 135—140°, with an extremely bitter taste, and contain-

* and *J. Pharm. Chim.*, 1913, [vii], 7, 444—448.

ing $C = 63\cdot5\%$ and $H = 8\cdot4\%$ (compare Finnemore, T., 1908, **93**, 1513; P., 1909, **25**, 77). F. M. G. M.

The Blue Pigment from Crenilabrus pavo. RICHARD VON ZEYNEK (*Monatsh.*, 1913, **34**, 535—551. Compare A., 1902, i, 168). —A fuller account of the blue protein substance present in the fins, scales, and skin of *Crenilabrus pavo*. The fins, which are the best source of the substance, are extracted with acetone and ether successively, which remove a yellow *substance*, microscopic needles; this is easily soluble in chloroform, giving a solution which, on treatment with acetic anhydride and a drop of concentrated sulphuric acid, assumes a deep red colour, shortly changing to a bluish-green. After the above treatment, the fins are extracted with water, which dissolves out the coloured substance; this is purified by repeated precipitation by ammonium sulphate, and obtained as an amorphous solid. The optical properties of the substance have been re-investigated. The addition of magnesium sulphate, ammonium chloride, or sodium chloride causes the substance to separate slowly from its aqueous solution, and it is precipitated by the ordinary alkaloid reagents; its neutral solution coagulates at 75—77°, precipitating green flocks. The colour is only slowly bleached by hydrogen peroxide and hydrazine hydrate, but it is very sensitive towards acids, which evidently cause decomposition, as subsequent neutralisation fails to restore the original colour.

Chlorophyll. XXI. Introduction of Magnesium into Chlorophyll Derivatives. RICHARD WILLSTÄTTER and LENNART FORSÉN (*Annalen*, 1913, **396**, 180—193).—It has previously been shown that metals, such as copper, iron, and zinc, can easily be introduced into derivatives of chlorophyll, such as the phæophorbides, phytochlorins, phytorhodins, and the various porphyrins, producing substances which are characterised by their stability in acid or alkaline media. Also derivatives of the phytochlorins and the phytorhodins have been prepared containing barium or potassium, and characterised by their instability towards acids. The magnesium derivatives are intermediate between these two extremes in their degree of stability. The present paper deals with the important problem of the methods whereby magnesium can be introduced into chlorophyll derivatives which do not contain a metallic constituent.

Two methods are described: heating the chlorophyll derivative with methyl-alcoholic potassium hydroxide and magnesium oxide under pressure, and secondly, treating it with an excess of ethereal magnesium methyl iodide.

Thus by heating phytochlorin-*e* (violet modification) with concentrated methyl-alcoholic potassium hydroxide and magnesium oxide in a silver autoclave at 180°, isolating the resulting potassium salt, and acidifying it with sodium dihydrogen phosphate, a new phyllin, called *cyanophyllin*, $C_{33}H_{34}O_4N_4Mg,Et_2O$, is obtained; it is a greenish-blue substance, characterised by the colour and fluorescence of its solutions and by its extraordinary instability, whereby the corresponding porphyrin is produced.

At 200° under similar conditions, phytochlorin-*e* is converted into a second phyllin, called *erythrophyllin*, $C_{33}H_{34}O_4N_4Mg$, which forms a red, fluorescent solution in ether. Still under the same conditions, phytochlorin-*e* at 220° is converted into phyllophyllin, $C_{32}H_{34}O_2N_4Mg$, which has previously been analysed only in the form of its salts on account of its instability. Phyllophyllin forms a bluish-red fluorescent ethereal solution, and readily loses its magnesium, yielding phylloporphyrin.

By treatment with magnesium methyl iodide (1 or 2 mols.) in ether, phæophytin-*a* yields precipitates containing magnesium and iodine, from which, however, the phæophytin is regenerated by treatment with water or other reagents. With an excess of magnesium methyl iodide (8 mols.), chlorophyll yields a substance from which unchanged chlorophyll is regenerated by treatment with sodium dihydrogen phosphate. In a similar manner the precipitate obtained from phæophytin-*a* and magnesium methyl iodide (8 mols.) yields, when rapidly treated with 10% sodium dihydrogen phosphate, pure chlorophyll-*a* identical with the substance prepared from natural sources.

In a similar manner, all porphyrins can be converted into the corresponding phyllins; thus phylloporphyrin methyl ester and magnesium methyl iodide in boiling ether yield a substance by the decomposition of which by sodium dihydrogen phosphate the methyl ester of phyllophyllin, $C_{33}H_{36}O_2N_4Mg$, is obtained in large, rhombic leaflets.

C. S.

[**Action of Sodium Methoxide on Bilirubic Acid, Bilirubin, and Hemibilirubin.**] OSKAR PILOTY (*Ber.*, 1913, **46**, 1000—1001).— Polemical (compare Fischer and Róse, A., 1912, i, 575; this vol., i, 382; also Piloty and Thannhauser, A., 1912, i, 736, 925). Bilic and bilirubic acids are the same substance; further, *iso*phonopyrrolecarboxylic acid is identical with the *iso*phonopyrrolecarboxylic acid of Fischer and Bartholomäus (A., 1912, i, 493), whilst dehydrobilic acid represents Fischer's xanthopyrrolecarboxylic acid or xanthobilirubic acid. The former name is to be preferred in each instance.

E. F. A.

The **Action of Hydrogen Peroxide on Hippomelanin.** JENNY ADLER-HERZMARK (*Biochem. Zeitsch.* 1913, **49**, 130—136).— Hippomelanin, obtained from melanotic lymph glands of a horse, dissolves in hydrogen peroxide when treated by the method of Rona and Riesser. About two-thirds of the nitrogen is thereby obtained in the form of ammonia. Part of the substance is converted into a product of the nature of melanic acid, which has been obtained from melanin by other methods. This product is slightly soluble in water, and is obtained in solution by the above-mentioned treatment in the form of an ammonium salt, from which the free acid can be precipitated by mineral acids, and from which an insoluble mercury salt can be obtained. No evidence could be obtained of the formation of guanidine or other basic organic substances.
S. B. S.

Furoylformic Acid and Furylglycollic Acid. EMIL FISCHER and FRITZ BRAUNS (*Ber.*, 1913, **46**, 892—896).—The similarity of pyromucic acid to benzoic acid extends even to the conversion through the chloride and cyanide into the corresponding ketonic acid.

Pyromucyl chloride, obtained from pyromucic acid and thionyl chloride, was treated in cooled ethereal solution with hydrogen cyanide and pyridine; the resultant oil was separated by distillation into a distillate of *furoyl cyanide*, hexagonal tablets, m. p. 25°, b. p. 32°/ 0·15 mm., and a residue of pyromucic anhydride. Furoyl cyanide is converted by dilute sodium hydroxide, or slowly by moist ethereal solution, largely into pyromucic acid. When kept with hydrochloric acid (D 1·19) for twenty-four hours, *furoylformic acid*, $C_4H_3O\cdot CO\cdot CO_2H$, is formed, which separates in colourless, microscopic needles, m. p. 94—95°, when the ethereal extract is treated with light petroleum; *silver* salt, amorphous; *phenylhydrazone*, m. p. near 154° (decomp.). The reduction of furoylformic acid by shaking with sodium amalgam and water yields *furylglycollic acid*, $C_4H_3O\cdot CH(OH)\cdot CO_2H$, m. p. indefinite at 114° (decomp.); the *calcium*, *silver*, and *lead* salts were prepared. Furoylformic acid thus shows marked similarity to benzoylformic acid.

D. F. T.

Hydroxycatechin and Catechincarboxylic Acids. MAXIMILIAN NIERENSTEIN (*Annalen*, 1913, **396**, 194—200).—*Hydroxycatechin* (annexed formula), m. p. 284—285° (decomp.), prepared by the reductive acetylation of catechone by acetic anhydride and zinc dust and hydrolysis of the product, crystallises in yellow needles and forms a colourless *hexamethyl ether*, m. p. 102°, by treatment with diazomethane.

The yellow colour of hydroxycatechin, as also the red colour of 1 : 2 : 7 : 8-tetrahydroxydiphenylene oxide, is attributed to the influence of the hydroxyl group in the peri-position to the oxygen atom of the furan ring. Consequently, the presence of the more strongly acidic carboxyl group in the place of the peri-hydroxyl group should produce a still more intensely coloured catechincarboxylic acid. The interaction of catechin, carbon tetrachloride, and aqueous potassium hydroxide, however, leads to the formation of a colourless *catechincarboxylic acid*, m. p. 274—277° (decomp.), needles, which has the constitution $CO_2H\cdot C_6H_2(OH)_2\cdot CH(OH)\cdot C_6H(OH)_2{<}^{O}_{CH_2}{>}CH_2$, since the *methyl catechincarboxylate pentamethyl ether*, $C_{22}H_{26}O_8$, m. p. 92°, obtained from it by the action of diazomethane, yields hemipinic acid by oxidation with alkaline potassium permanganate.

The catechincarboxylic acid has been resolved by means of its strychnine salts into the optically active components. l-*Catechincarboxylic acid* crystallises in small needles and has m. p. 270—273° (decomp.), and $[a]_D^{18} - 68\cdot 22°$ in alcohol; the d-*acid*, small needles, has m. p. 273° (decomp.) and $[a]_D^{18} + 76\cdot 4°$ in alcohol. C. S.

Adrenaline from the Whale. EDWARD R. WEIDLEIN (*J. Ind. Eng. Chem*, 1912, **4**, 636—645).—The suprarenal glands of the whale are found to be about 500 times larger than those of sheep and fifty times larger than those obtained from cattle.

From the tabulated results of numerous experiments the conclusion is drawn that glands preserved in chloroform yield about 0·2% pure adrenaline (m. p. 212°, $[a]_D^{25}$ −52·00°) after preservation during six to nine months, the loss during purification amounting to 13·8%. Pure adrenaline gives a marked increase in blood pressure (as shown by curves) without a subsequent depressant action, this latter effect being considered to be due to impurities, proteins (such as lecithin and phosphates) present in the glands, and to decomposition products which are formed by oxidation on keeping for even a a short time in aqueous solution.

The commercial adrenaline used for comparison gave the secondary depressant action until purified, although declared to be the best on the market.

The extraction and purification of the active suparenal principle from the whale, cattle, sheep, and pigs is described, and it is demonstrated to be identical from each source.   F. M. G. M.

Berberine. MARTIN FREUND (*Annalen*, 1913, **397**, 1—30).—A general discussion of the results of researches on dihydroberberine derivatives (compare following abstracts), one of the most important being the conversion of berberine into hydrastinine by a smooth and practicable method.   C. S.

Derivatives of Benzyldihydroberberine. MARTIN FREUND and KARL FLEISCHER (*Annalen*, 1913, **397**, 30—52).—Benzyldihydroberberine (Freund and Beck, A., 1905, i, 151) yields the stannichloride of *benzyltetrahydroberberine*,

$$C_6H_2(OMe)_2\underset{CH(CH_2Ph)\cdot N\cdot CH_2\cdot CH_2}{\overset{CH_2\text{———}CH\text{———}}{\Big\langle}}C_6H_2\text{:}CH_2O_2,$$
m. p. 163—165°, pale yellow, rhombic plates (*hydrochloride*, white needles ; *sulphate*, decomp. 227° ; *nitrate*, decomp. 175°), by reduction with stannous chloride and boiling 96% alcohol and hydrochloric acid, D 1·19. A second base is not formed, but when benzyldihydroberberine, dissolved in alcohol and 30% sulphuric acid, is reduced at a lead cathode at 50—60° (current-density at the cathode 0·06 ampere per sq. cm.), benzyltetrahydroberberine is produced, together with an *isomeride*, $C_{27}H_{27}O_4N$, m. p. 126°, a grey, crystalline powder, which is called *ψ-benzyltetrahydroberberine.* With methyl iodide at 100° it forms a *methiodide*, decomp. 200°, yellow powder, whilst *benzyltetrahydroberberine methiodide*, colourless, rhombic plates, has decomp. 224°. Both methiodides, by treatment with silver oxide and 50% alcohol and then with boiling potassium hydroxide, yield the same tertiary base, *de-benzyl-N-methyltetrahydroberberine*, $C_{28}H_{29}O_4N$, m. p. 121—122·5°, colourless, quadratic plates (*sulphate*, m. p. 209—210° ; *hydrochloride*, decomp. 238—240° ; *hydriodide*, m. p. 193—194°). Since de-benzyl-*N*-methyltetrahydroberberine is converted into hydrastinine and 3 : 4-dimethoxy-2-styrylbenzaldehyde by oxidation with sodium dichromate in boiling acetic acid (this fissive oxidation is quite similar
to that of landanosine described by Pyman [T., 1909, **95**, 1267]), it receives the formula :

$$CHPh{:}CH{\cdot}C_6H_2(OMe)_2{\cdot}CH_2{\cdot}CH{<}^{C_6H_2(:CH_2O_2)}_{NMe{-}{-}{-}CH_2}{>}CH_2,$$
although, perhaps, a constitution containing the annexed skeleton is in better agreement with the facts that the de-base cannot be reduced and does not react with bromine.

3 : 4-*Dimethoxy-2-styrylbenzaldehyde,*

$$CHPh{:}CH{\cdot}C_6H_2(OMe)_2{\cdot}CHO,$$
m. p. 71—74°, long, colourless needles, does not react with bromine in chloroform (steric hindrance ?), and forms an *oxime*, m. p. 125—140°, *phenylhydrazone,* m. p. 120—122°, yellow needles, *semicarbazone,* m. p. 190—192°, and *anil,* m. p. 107—109°; by reduction with sodium and warm alcohol, it is converted into 3 : 4-*dimethoxy-2-β-phenylethylbenzyl alcohol,* $CH_2Ph{\cdot}CH_2{\cdot}C_6H_2(OMe)_2{\cdot}CH_2{\cdot}OH$, m. p. 96—98°, colourless needles.

De-benzyl-*N*-methyltetrahydroberberine forms with methyl iodide at 100° a *methiodide,* m. p. 210°, yellow plates, which is converted, by successive treatment with silver oxide and 50% alcohol and with boiling potassium hydroxide, into *de-benzyl-NN-dimethyltetrahydroberberine,* $C_{20}H_{31}O_4N$, m. p. 93—94·5° (*sulphate,* m. p. 197°; *hydrochloride,* m. p. 238°), which cannot be reduced and is given the formula

$$CHPh{:}CH{\cdot}C_6H_2(OMe)_2{\cdot}CH{:}CH{\cdot}C_6H_2(:CH_2O_2){\cdot}CH_2{\cdot}CH_2{\cdot}NMe_2,$$

because it yields 3 : 4-dimethoxy-2-styrylbenzaldehyde by fissive oxidation. It forms a *methiodide,* m. p. 268°, which is decomposed and yields trimethylamine and 3 : 4-*dimethoxy-3' : 4'-methylenedioxy-2-styryl-6'-vinylstilbene,*

$$CHPh{:}CH{\cdot}C_6H_2(OMe)_2{\cdot}CH{:}CH{\cdot}C_6H_2(CH{:}CH_2){<}^{O}_{O}{>}CH_2,$$
m. p. 120—122°, colourless needles, by the usual treatment.

Benzyldihydroberberine and methyl iodide at 100° yield a *substance,* decomp. 181°, which is not a methiodide, because it loses hydrogen iodide by treatment with alcoholic ammonia and yields a *substance,* $C_{26}H_{27}O_4N$, m. p. 187—188°, pale yellow, rhombic plates, which is called *de-benzyl-N-methyldihydroberberine*; the hydriodide of the latter is identical with the original additive compound. The constitution of de-benzyl-*N*-methyldihydroberberine has not been definitely settled; either of the annexed formulæ may be possible, and serves to explain many of the following transformations of the substance, but objections can be raised against both :
De-benzyl-N-methyldihydroberberine forms a *methiodide*,

$$C_{28}H_{27}O_4NMeI,H_2O,$$
decomp. 167°, reddish-yellow prisms, and is reduced by stannous chloride and boiling alcohol and hydrochloric acid, D 1·19, to the stannichloride of a *substance*, $C_{28}H_{29(or\ 31)}O_4N$, m. p. 162·5—164°, colourless leaflets (*hydrochloride*, decomp. about 215°; *sulphate*, decomp. above 170°), which is called *α-hydro-de-benzyl-*N-*methyldihydroberberine*. It is unchanged by bromine, iodine, or methyl iodide, and has only faintly basic properties. By reduction at a lead cathode in alcohol and 30% sulphuric acid at 40—50°, and with a cathodic current density of 0·075 ampere per sq. cm. and at 24 volts, de-benzyl-N-methyldihydroberberine is converted into a mixture of α-hydro-de-benzyl-N-methyldihydroberberine and a *substance*, $C_{28}H_{29(or\ 31)}O_4N$, m. p. 134—136°, microscopic plates, which is called *β-hydro-de-benzyl-*N-*methyldihydroberberine*. The mixture is readily separated, since only the β-compound forms a *methiodide*. Analysis fails to determine whether the α- and β-compounds are isomeric or whether one contains more hydrogen than the other. The preceding methiodide is converted, by treatment with silver oxide and subsequent boiling with an alkali, into *β-hydro-de-benzyl-*NN-*dimethyldihydroberberine*, $C_{29}H_{31(or\ 33)}O_4N$, m. p. 126°, colourless needles, the *methiodide*, decomp. 239°, of which yields trimethylamine and a non-nitrogenous substance by the usual treatment.

The oxidation of de-benzyl-N-methyldihydroberberine by sodium dichromate and acetic acid at 90° produces, after dilution with water, a yellow (unexamined) solid and a green solution. Sodium carbonate precipitates from the latter *dehydro-de-benzyl-*N-*methyldihydroberberine* (annexed formula), m. p. 203—204°, yellow prisms, which forms a *hydrochloride* and *sulphate*, decomp. 229°, but not a methiodide. By reduction with stannous chloride, alcohol, and concentrated hydrochloric acid, or at a lead cathode in alcohol and 30% sulphuric acid at 40—50°, dehydro-de-benzyl-N-methyldihydroberberine is converted into a *substance*, $C_{28}H_{27(or\ 29)}O_4N$, m. p. 164—165°, pale yellow, hexagonal plates, which appears to be isomeric with α-hydro-de-benzyl-N-methyldihydroberberine.

Benzyltetrahydroberberine methiodide in aqueous alcoholic suspension is converted by silver chloride into the *methochloride*, decomp. 228°, rhombic plates, an aqueous solution of which on the water-bath is converted by 5% sodium amalgam into de-benzyl-N-methyltetrahydroberberine and iso*hydro-de-benzyl-*N-*methyltetrahydroberberine*, $C_{28}H_{31}O_4N$, m. p. 96—98°, colourless plates (*hydriodide*, m. p. 229° [decomp.]).

C. S.

Methyldihydroberberine and its Derivatives. MARTIN FREUND and HANNS COMMESSMANN (*Annalen*, 1913, 397, 52—56).—Alkyl- or aryl-dihydroberberines react with methyl iodide to form the hydriodides of bases called de-alkyl-(or aryl-)-N-methyldihydroberberines; by the

electrolytic method, each of the de-bases yields two reduction products, a- and β-hydro-de-alkyl-(or aryl-)-N-methyldihydroberberines. Since these reduction products have similar properties, whether the alkyl or aryl group is methyl, ethyl, *isopropyl*, *isobutyl*, *isoamyl*, benzyl, or phenyl, the de-bases all have the same constitution, namely, that already given for the benzyl compound (Freund and Fleischer, preceding abstract).

By reduction, R-dihydroberberines each yield two stereoisomeric R-tetrahydroberberines, from which two stereoisomeric R-tetrahydroberberine methiodides (formula I) are obtained. (R-Tetrahydroberberines do not combine additively with iodides other than methyl iodide.) By treatment with silver oxide and subsequently with boiling alkali, the two methiodides yield one and the same de-base, which may have the constitution II, III, or IV. When R is CH_2Ph, the de-base has formula II (Freund and Fleischer, preceding abstract); when R is $Pr\beta$, the de-base has constitution III (Freund and Lachmann, following abstract); when R is Me, Et, $CH_2Pr\beta$, $CH_2 \cdot CH_2Pr\beta$, n-C_8H_{17}, or Ph, the de-base has formula IV.

(I.) (II.) (III.) (IV.)
*Methyltetrahydroberberine methiodide*, $C_{22}H_{26}O_4NI$, m. p. 263—264°, colourless prisms, is converted by the usual method into *de-methyl-N-methyltetrahydroberberine*, $C_6H_2(OMe)_2 < \begin{array}{l} CH_2 \!-\! CH \!-\! C_6H_2 \!:\! CH_2O_2 \\ CHMe \cdot NMe \quad CH \!:\! CH_2 \end{array}$, m. p. 115—116°, colourless prisms (*hydrochloride*, m. p. 224—225° [decomp.]; *sulphate*, m. p 211—212°; *nitrate*, m. p. 198—199° [decomp.]). The de-base does not yield hydrastinine by oxidation (de-benzyl-N-methyltetrahydroberberine is the only one that does), and forms a *methiodide*, m. p. 257° (decomp.), colourless needles.

Methyldihydroberberine and methyl iodide form the *hydriodide*, m. p. 218° (decomp.), yellowish-green needles, of *de-methyl-N-methyl-dihydroberberine*, $C_{21}H_{23}O_4N$, m. p. 155°, yellow, irregular prisms (*sulphate*, m. p. 116° [decomp.]; *hydrochloride*, m. p. 104°). By electrolytic reduction at a lead cathode in alcohol and 20% sulphuric acid, the de-base is converted into *a-hydro-de-methyl-N-methyldihydroberberine*,

$C_{22}H_{25}O_4N$, m. p. 146° (*sulphate*, m. p. 223° [decomp.]; *hydrochloride*, m. p. 155° [decomp.]; *nitrate*, decomp. 198°), and *β-hydro-de-methyl-N-methyldihydroberberine*, $C_{22}H_{25}O_4N$, m. p. 215° (*sulphate*, m. p. 135—138° [decomp.]; *hydrochloride*, decomp. 220°; *nitrate*, decomp. 234°). The constitutions of the de-base and its reduction products are analogous to those of de-benzyl-*N*-methyldihydroberberine and its reduction products (Freund and Fleischer, preceding abstract). C. S.

Ethyldihydroberberine and Its Derivatives. MARTIN FREUND and HANNS COMMESSMANN (*Annalen*, 1913, **397**, 57—69).—The reduction of ethyldihydroberberine at a lead cathode yields Freund and Mayer's ethyltetrahydroberberine, m. p. 151° (A., 1905, i, 657), and *ψ-ethyltetrahydroberberine*, $C_{22}H_{25}O_4N$, m.p. 117—119°, faintly yellowish-green, irregular plates, which forms a *sulphate*, m. p. 236° (decomp.), *hydrochloride*, decomp. 248°, and *nitrate*, decomp. 210°.

Ethyltetrahydroberberine and methyl iodide at 100° yield the *methiodide*, $C_{22}H_{25}O_4N$MeI, m. p. 228—229°, colourless needles, which is converted by the usual process into *de-N-methyl-a-ethyltetrahydroberberine*,

$$C_6H_2(OMe)_2{<}^{CH_2-CH-C_6H_2 \cdot CH_2O_2}_{CHEt \cdot NMe\ CH:CH_2}$$

m. p. 134° (*hydrochloride*, decomp. 220°; *sulphate*, decomp. 239°; *nitrate*, decomp. 152°). The de-base does not yield hydrastinine by oxidation, is also produced by the successive action of silver oxide and potassium hydroxide on *ψ-ethyltetrahydroberberine methiodide*, m. p. 211° (decomp), and is reduced at a lead cathode in alcohol and 20% sulphuric acid to *hydro-de-N-methylethyltetrahydroberberine*,

$$C_6H_2(OMe)_2{<}^{CH_2}_{CHEt \cdot NMe}{>}CH \cdot C_6H_2Et:CH_2O_2,$$

m. p. 124—125° (*sulphate*, m. p. 230°; *hydrochloride*, m. p. 243°). De-*N*-methylethyltetrahydroberberine and methyl iodide at 100° form the *methiodide*, $C_{23}H_{27}O_4N$MeI, decomp. 230°, which is converted by silver oxide and potassium hydroxide in the usual manner into *de-NN-dimethylethyltetrahydroberberine*, $C_{24}H_{29}O_4N$, m. p. 85—86°. The *methiodide*, m. p. 208—209°, of the latter is decomposed into trimethylamine and 3:4-*dimethoxy*-3':4'-*methylenedioxy*-2-*propenyl*-6'-*vinyl-stilbene*, $CHMe:CH \cdot C_6H_2(OMe)_2 \cdot CH:CH \cdot C_6H_2(:CH_2O_2) \cdot CH:CH_2$, m. p. 82—83°, stout needles, by the usual treatment.
Ethyldihydroberberine and methyl iodide yield the *hydriodide*, m. p. 210° (decomp.), of *de-N-methylethyldihydroberberine*, $C_{23}H_{25}O_4N$, m. p. 142—143°, softening at 136—137°. The de-base forms a *methiodide*, $C_{23}H_{25}O_4N$MeI, m. p. 250° (decomp.), which yields by the usual method of decomposition *de-NN-dimethylethyldihydroberberine*, $C_{24}H_{27}O_4N$, m. p. 115—116° (*sulphate*, m. p. 191—192° [decomp.]; *nitrate*, decomp. 168°; *hydrochloride*, decomp. 163—164°).

The reduction of de-*N*-methylethyldihydroberberine at a lead cathode in alcohol and 20% sulphuric acid yields a mixture of *a-hydro-de-N-methylethyldihydroberberine*, $C_{23}H_{27}O_4N$, m. p. 137°, and *β-hydro-de-N-methylethyldihydroberberine*, $C_{23}H_{27}O_4N$, m. p. 168°. The *a*-base forms a *sulphate*, decomp. 188°, *hydrochloride*, decomp. 266°, and *nitrate*, decomp. 170°, does not form a methiodide, and is converted

into de-*N*-methylethyldihydroberberine by bromine in chloroform and basification of the product. The β-base is unattacked by bromine, and forms a *sulphate*, decomp. 107—108°, *hydrochloride*, decomp. 250°, *nitrate*, decomp. 185°, and *methiodide*, m. p. 245° (decomp.). The decomposition of the last in the usual manner by silver oxide and potassium hydroxide yields a *substance*, m. p. 104—120°, which is probably a mixture of two isomeric β-*hydro-de-*NN-*dimethylethyldihydroberberines* (formulæ I and II); the *methiodide* has decomp. 230°.

(I.)   (II.)
By oxidation with sodium dichromate and acetic acid at 80°, de-*N*-methylethyldihydroberberine yields a *substance*, $C_{28}H_{27}O_6N$, m. p. 130° (decomp.) (*hydrochloride*, m. p. 225°, colourless needles), which is called *oxy-de-N-methylethyldihydroberberine hydrate*, and possibly has the annexed constitution. This substance is also produced by

the oxidation of α- or β-hydro-de-*N*-methylethyldihydroberberine; in addition, a second *substance*, $C_{23}H_{25(or\ 23)}O_4N$, m. p. 178°, yellow crystals, is formed, which is provisionally named iso-*de-N-methylethyldihydroberberine*.   C. S.

*iso*Propyldihydroberberine and its Derivatives. MARTIN FREUND and ROBERT LACHMANN (*Annalen*, 1913, **397**, 70—84).— Berberine sulphate and ethereal magnesium *iso*propyl bromide react to form, after the usual treatment, iso*propyldihydroberberine*,

$$C_6H_2(OMe)_2 \begin{matrix} CH=\!\!=\!C \cdot C_6H_2(:CH_2O_2) \\ CHPr^\beta \cdot N \underline{\hspace{2em}} CH_2 \end{matrix} CH_2,$$

m. p. 167—168°, citron-yellow needles. By electrolytic reduction in alcohol and 20% sulphuric acid at 50—60° and a current density 0·06 ampere per sq. cm. at the cathode, *iso*propyldihydroberberine yields the two stereoisomerides, iso*propyltetrahydroberberine*,

$$C_6H_2(OMe)_2 \begin{matrix} CH_2\underline{\hspace{1em}}CH \cdot C_6H_2(:CH_2O_2) \\ CHPr^\beta \cdot N \underline{\hspace{2em}} CH_2 \end{matrix} CH_2$$

m. p. 157—158°, greenish-yellow, rhombic leaflets (*sulphate*, m. p. 197° [decomp.]; *nitrate*, decomp. 215°; *hydrochloride*, decomp. 226°; *platinichloride*, decomp. 205°; *perchlorate*, m. p. 226—227° [decomp.]), and ψ-iso*propyltetrahydroberberine*, m. p. 200—202°, colourless prisms (*nitrate*, decomp. 176°; *hydrochloride*, decomp. 254°). By treatment with alcoholic iodine at 100°, *iso*propyltetrahydroberberine is converted

into iso*propyldihydroberberine* *hydriodide*, $C_{23}H_{25}O_4N,HI,Et\cdot OH$, decomp. 110°, brown, rhombic plates, whilst the ψ-base is simply converted into its hydriodide.

iso*Propyltetrahydroberberine* *methiodide*, m. p. 210° (decomp.), colourless needles, and ψ-iso*propyltetrahydroberberine* *methiodide*, decomp. 247—248°, faintly yellow needles, each yield, by treatment with silver oxide and 50% alcohol, and subsequently with boiling potassium hydroxide, a mixture of a-*de-N-methyl*iso*propyltetrahydroberberine*, $C_{24}H_{29}O_4N$, m. p. 132·5° (*sulphate*. decomp. about 200°; *hydriodide*, decomp. 197°, yellow needles), and b-*de-N-methyl*iso*propyltetrahydroberberine*, $C_{24}H_{29}O_4N$, m. p. 102—103° (*hydrochloride*, decomp. 226°; *hydriodide*, decomp. 218°; *nitrate*, decomp. 197°). The a-*de*-base is converted into the b-*de*-base by boiling alcohol, and yields ψ-iso*propyltetrahydroberberine* methiodide by digestion with aqueous alcohol and subsequent treatment with acetic acid and potassium iodide; it is unchanged by boiling nitrobenzene, by boiling dilute sulphuric acid and alcohol, or by electrolytic reduction. The b-*de*-base is comparatively stable. By prolonged boiling with glacial acetic acid and subsequent treatment of the basified and filtered solution with potassium iodide, it yields a *methiodide*, m. p. 236°, from which the b-*de*-base is regenerated directly.

Of all the *de*-bases examined by the authors (preceding and following abstracts), a-*de-N*-methyl*iso*propyltetrahydroberberine is the only one which resembles Gadamer and Voss's ethyl anhydro-base of tetrahydroberberine (A., 1910, i, 415) in being readily re-converted into the ammonium base or its salts by digestion with water or acids. The a-*de*-base, therefore, is given the constitution

$$C_6H_2(OMe)_2 \begin{array}{c} CH:CH\cdot C_6H_2(:CH_2O_2) \\ CHPr^\beta\cdot NMe\text{———}CH_2 \end{array} > CH_2,$$
analogous to that of the ethyl anhydro-base of tetrahydroberberine. The b-*de*-base and all other de-alkyl (or -aryl-)-*N*-methyltetrahydroberberines have the only remaining constitution:

$$C_6H_2(OMe)_2 \begin{array}{c} CH_2\text{—}CH\text{—}C_6H_2:CH_2O_2 \\ CHR\cdot NMe \quad CH:CH_2 \end{array}$$
(compare preceding abstract). Given these constitutions, the preceding transformations of a- and b-*de-N*-methyl*iso*propyltetrahydroberberine become readily explicable. By electrolytic reduction, the b-*de*-base yields *hydro-b-de-N-methyl*iso*propyltetrahydroberberine*,
$$C_6H_2(OMe)_2 \begin{array}{c} CH_2\text{———}CH\cdot C_6H_2Et:CH_2O_2 \\ CHPr^\beta\cdot NMe \end{array}$$
colourless needles containing alcohol, m. p. 74—80° (*hydrochloride*, $C_{24}H_{31}O_4N,HCl$, decomp. 261°).

b-*De-N-methyl*iso*propyltetrahydroberberine methiodide*, $C_{24}H_{29}O_4NMeI$, colourless prisms (the a-*de*-base does not form a methiodide), is converted by the usual method into *de-NN-dimethyl*iso*propyltetrahydroberberine*, $C_{25}H_{31}O_4N$, m. p. 112—115°, colourless needles (*sulphate*, decomp. about 190°). iso*Propyldihydroberberine* and methyl iodide at 100° yield the *hydriodide*, decomp. 229°, yellow needles, of *de-N-methyl*iso*propyldihydroberberine*, $C_{24}H_{27}O_4N$ (for constitution, compare Freund and Fleischer, preceding abstract), m. p. 170—171°, pale

yellow crystals (*perchlorate*, decomp. 213°; *methiodide*, decomp. 232°, golden-yellow, rhombic prisms).

The electrolytic reduction of de-N-methyl*iso*propyldihydroberberine in alcohol and 20% sulphuric acid at 50—60° yields a mixture of a - *hydro* - *de* - N - *methyliso*propyldihydroberberine, $C_{24}H_{29}O_4N$, m. p. 164·5—166°, greenish-yellow, rhombic plates (*nitrate*, decomp. 185°, rhombic plates; *sulphate*, m. p. 197°, prisms; *hydrochloride*, m. p. about 218°, needles; *hydriodide*, m. p. 234°; *perchlorate*, decomp. 236°), and β - *hydro* - *de* - N - *methyliso*propyldihydroberberine, $C_{24}H_{29}O_4N$, m. p. 184—186°, almost colourless, rhombic prisms (*nitrate*, decomp. 188°; *hydriodide*, decomp. 226—227°). The a-compound does not form a methiodide, and yields de-N-methyl*iso*propyldihydroberberine by treatment with bromine in chloroform and basification of the product. The β-base forms a *methiodide*, $C_{24}H_{29}O_4N,MeI$, decomp. 253°, and is unchanged by bromine. By oxidation with sodium dichromate and acetic acid at 80—90°, de-N methyl*iso*propyldihydroberberine and its a- and β-hydro-derivatives each yield the same product, *hydroxy-de-*N-*methyl*isopropyldi*hydroberberine hydroxide* (annexed formula?), decomp. 129°, light brown crystals, which forms a *hydrochloride*, decomp. about 205°, and *hydriodide*, decomp. 238°. C. S

*iso*Butyldihydroberberine and Its Derivatives. MARTIN FREUND and HAROLD HAMMEL (*Annalen*, 1913, 397, 85—93).—iso-*Butyldihydroberberine*, $C_{24}H_{27}O_4N$, m. p. 112—113°, yellow needles, leaflets, or prisms, prepared in the usual manner from berberine hydrochloride and ethereal magnesium *iso*butyl bromide, forms a *nitrate*, m. p. 205° (decomp.), pale yellow leaflets, *hydriodide*, m. p. 223° (decomp.), yellow leaflets, and *platinichloride*, decomp. 220°, orange needles. It reacts with methyl iodide to form the *hydriodide*, m. p. 206° (decomp.), pale yellow needles, of *de-*N-*methyl*isobutyldihydro*berberine*, $C_{25}H_{29}O_4N$, m. p. 147—148° (*hydrochloride*, m. p. 148° [decomp.]; *platinichloride*, m. p. 217°; *hydrobromide*, m. p. 115—120° [decomp.]). The de-base is unchanged by bromine in chloroform, and forms a *methiodide*, $C_{25}H_{29}O_4NMeI$, m. p. 172° (decomp.), pale yellow leaflets, which is converted in the usual manner into *de-*NN-*dimethyl-isobutyldihydroberberine*, $C_{26}H_{31}O_4N$, m. p. 130—131°, almost colourless plates. The *methiodide* of the last substance, $C_{26}H_{31}O_4NMeI$, m. p. 164° (decomp.), yellow needles, decomposes into methyl iodide and the original base when heated at about 95° or boiled with aqueous alcoholic potassium hydroxide; the base is also obtained when the methiodide is treated successively with silver oxide and boiling potassium hydroxide.

By reduction at a lead cathode in alcohol and 25% sulphuric acid, de-N-methyl*iso*butyldihydroberberine yields a mixture of a-*hydro-de-*N-*methylisobutyldihydroberberine*, $C_{25}H_{31}O_4N$, m. p. 158—160°, almost

colourless, rhombic plates (*hydrobromide*, decomp. 223°; *hydriodide*, m. p. 189°), and β-*hydro-de-*N-*methyl*iso*butyldihydroberberine*, $C_{25}H_{31}O_4N$, m. p. 179° (*hydrochloride*, decomp. about 240°; *hydrobromide*, m. p. 239°; *hydriodide*, m. p. 239° [decomp.]). The α-compound does not form a methiodide, and is converted into de-N-methyliso*butyldi*-hydroberberine by treatment with bromine in chloroform and basification of the product. The β-compound is unchanged by bromine, and forms a *methiodide*, $C_{25}H_{31}O_4N,MeI$, m. p. 246° (decomp.), which regenerates the β-compound by heating at 240°, and is converted by successive treatment with silver oxide and boiling potassium hydroxide into β-*hydro-de-*NN-*dimethyl*iso*butyldihydroberberine*, $C_{26}H_{33}O_4N$, m. p. 136—137°, colourless, rhombic leaflets. By electrolytic reduction at a lead cathode in sulphuric acid, isobutyldihydroberberine yields a mixture of iso*butyltetrahydroberberine*, $C_{24}H_{29}O_4N$, m. p. 127—129°, greenish-yellow, rhombic leaflets (*hydrochloride*, m. p. 237°; *hydriodide*, m. p. 256°; *sulphate*, m. p. 234°; *methiodide*, m. p. 193°), and ψ-iso*butyl-tetrahydroberberine*, $C_{24}H_{29}O_4N$, m. p. 197°, colourless plates (*hydro-chloride*, m. p. 270—273° [decomp.]; *hydriodide*, m. p. 250° [decomp.]).

C. S.

n-Octyldihydroberberine and isoAmyldihydroberberine and their Derivatives. MARTIN FREUND and DANIEL STEINBERGER (*Annalen*, 1913, **397**, 94—106).—A suspension of berberine sulphate in ether, by treatment with ethereal magnesium *n*-octyl iodide and decomposition of the product by ice and hydrochloric acid, yields the *hydriodide*, $C_{28}H_{35}O_4N,HI,H_2O$, m. p. 122—124°, reddish-brown crystals, of *octyl-dihydroberberine*, $C_{28}H_{35}O_4N$, m. p. 88·5—89°, yellow needles. In a similar manner, berberine sulphate and magnesium iso*amyl bromide, after the addition finally of concentrated potassium iodide, yield the *hydriodide*, decomp. 141°, yellow crystals, of iso*amyldihydroberberine*, $C_{25}H_{29}O_4N$, an amorphous, yellow substance.

By reduction with stannous chloride, hydrochloric acid, D 1·19, and alcohol, isoamyldihydroberberine yields only iso*amyltetrahydroberberine*, $C_{25}H_{31}O_4N$, m. p. 95—96° (*sulphate*, decomp. 237°; *hydriodide*, decomp. 255°; *nitrate*, decomp. 209—210), whilst by reduction at a lead cathode in alcohol and 20% sulphuric acid at 40—50°, it yields, in addition, ψ-iso*amyltetrahydroberberine*, $C_{25}H_{31}O_4N$, m. p. 172° (*hydrochloride*, decomp. 231—232°; *hydriodide*, decomp. 239—240°; *nitrate*, decomp. 210—211°).

iso*Amyltetrahydroberberine methiodide*, decomp. 191°, and ψ-iso*amyl-tetrahydroberberine methiodide*, decomp. 223—224°, each yield, by the usual method of decomposition, de-N-*methyl*iso*amyltetrahydroberberine*, which forms a *hydrochloride*, $C_{25}H_{33}O_4N,HCl$, decomp. 185°, *sulphate*, decomp. 190—191°, and *hydriodide*, decomp. 224—225°, and does not yield hydrastinine by oxidation.

iso*Amyldihydroberberine and methyl iodide at 100° yield the *hydriodide* of de-N-*methyl*iso*amyldihydroberberine*, $C_{26}H_{31}O_4N$, m. p. 102°, pale yellow plates. By reduction with stannous chloride, hydro-chloric acid, and alcohol, the de-base yields α-*hydro-de-*N-*methyl*iso-*amyldihydroberberine*, $C_{26}H_{33}O_4N$, m. p. 128°, rhombic leaflets, which forms a *sulphate*, decomp. 187—188°, *nitrate*, decomp. 146°, *hydro-*

chloride, decomp. 232°, and *hydriodide,* decomp. 228°, does not form a methiodide, and is converted into de-*N*-methyl*iso*amyldihydroberberine by treatment with bromine in chloroform. By reduction at a lead cathode, de-*N*-methyl*iso*amyldihydroberberine yields, in addition to the preceding α-compound, *β-hydro-de-*N*-methyl*isoamyldihydroberberine,* $C_{26}H_{31}O_4N$, m. p. 145°, rhombic prisms (*hydrochloride,* decomp. 220—221°; *hydriodide,* decomp. 226—227°; *methiodide,* m. p. 260°).

By prolonged heating with alcoholic ammonia in the presence of air, *iso*amyldihydroberberine hydriodide is converted into *dehydroisoamyl-dihydroberberine,*

$$C_6H_2(OMe)_2 \big\langle {}^{C \!=\!\!=\!\!=\! C \cdot C_6H_2(:CH_2O_2)}_{C(C_5H_{11}) \cdot N \text{———} CH_2} \big\rangle CH_2(?),$$
m. p. 249° (decomp.), hexagonal, yellow plates, which rapidly darken in the air and light. The dehydro-compound yields *iso*amyl- and ψ-*iso*-amyl-tetrahydroberberines by electrolytic reduction, does not form salts with acids in the cold, and by boiling for eight to ten minutes with 96% alcohol and 20% hydrochloric acid or sulphuric acid, D 1·215, is converted into the *hydrochloride,* $C_{25}H_{29}O_5N,HCl$, decomp. 204°, yellow needles, or the *sulphate,* $C_{25}H_{29}O_5N,H_2SO_4$, decomp. 265°, yellow needles, of *hydroxyisoamyldihydroberberine,*

$$C_6H_2(OMe)_2 \big\langle {}^{C(OH) \!=\!\!=\!\! C \cdot C_6H_2(:CH_2O_2)}_{CH(C_5H_{11}) \cdot N \text{———} CH_2} \big\rangle CH_2,$$
m. p. 120—125°, sintering at 65°, dark yellow needles; a by-product of both reactions is a *substance,* decomp. 180—185°, reddish-brown, rhombic crystals.　　　　　　　　　　　　　　　　　　　　　　　　　　　C. S.

Phenyldihydroberberine and its Derivatives. MARTIN FREUND aud EUGEN ZORN (*Annalen,* 1913, **397,** 107—117).—Phenyldihydro-berberine (Freund and Beck, A., 1905, i, 151) forms a *hydrochloride,* m. p. 160°, yellow prisms, *sulphate,* decomp. 170°; pale yellow needles, *nitrate,* decomp. 224°, and *hydriodide,* m. p. 215°. By reduction at a lead cathode in alcohol and 30% sulphuric acid, it yields Gadamer's phenyltetrahydroberberine (*sulphate,* decomp. 241°), and ψ-*phenyltetra-hydroberberine,* $C_{26}H_{25}O_4N$, m. p. 204—205°, white needles (*hydriodide,* m. p 235°); only the former can be isolated when the reduction is effected by stannous chloride and boiling alcohol and hydrochloric acid.

Phenyltetrahydroberberine methiodide, m. p. 243°, faintly yellow plates, and ψ-*phenyltetrahydroberberine methiodide,* m. p. 247°, white crystals, yield methyl iodide and the respective bases by heating. By treatment with silver oxide and boiling potassium hydroxide in the usual manner, each methiodide yields *de-phenyl-*N*-methyltetrahydroberberine,*

$$C_6H_2(OMe)_2 \big\langle {}^{CH_2 \text{—} CH \text{—} C_6H_2:CH_2O_2}_{CHPh \cdot NMe \quad CH:CH_2} ,$$
m. p. 153°, which forms a *hydrochloride,* m. p. 232°, *hydriodide,* decomp. 208°, and *methiodide,* m.p. 238° (decomp.). By reduction at a lead cathode, the de-base is converted into *hydro-de-phenyl-*N*-methyltetrahydroberberine,*

$$C_6H_2(OMe)_2 \big\langle {}^{CH_2 \text{—} CH-}_{CHPh \cdot NMe} \big\rangle C_6H_2Et:CH_2O_2,\text{ m. p. 142—143° (}hydro\text{-}$$

chloride, m. p. 271—272°; *hydriodide,* m. p. 257°).

Phenyltetrahydroberberine methiodide is converted into the metho-

chloride in dilute alcohol, and the latter, after evaporation of the alcohol, is treated with 5% sodium amalgam on the water-bath. The product is 2-mp-*dimethoxy*-o-*benzylbenzylhydrastinine*,

$$CH_2Ph\cdot C_6H_2(OMe)_2\cdot CH_2\cdot CH{<}{\overset{\textstyle C_6H_2(:CH_2O_2)}{\underset{\textstyle NMe\text{——}CH_2}{}}}{>}CH_2,$$
m. p. 109·5—110·5°, colourless plates (*hydriodide*, m. p. 217—219°), from which hydrastinine is obtained by oxidation with sodium dichromate and acetic acid at 90°.

Phenyldihydroberberine and methyl iodide at 100° yield the *hydriodide*, m. p. 245°, yellow prisms, of *de-phenyl-N-methyldihydroberberine*, $C_{27}H_{25}O_4N$, m. p. 178—179°, yellow prisms (*sulphate*, m. p. 160°; *methiodide*, decomp. 220°). By reduction at a lead cathode in cold alcohol and 30% sulphuric acid, the de-base is converted into a mixture of *a-hydro-de-phenyl-N-methyldihydroberberine*, $C_{27}H_{27}O_4N$, m. p. 178—179°, yellow, rhombic prisms (*sulphate*, m. p. 206°, colourless prisms; no methiodide), and *β-hydro-de-phenyl-N-methyldihydroberberine*, $C_{27}H_{27}O_4N$, m. p. 211—212°, rhombic plates (*hydrochloride*, m. p. 257°; *methiodide*, m. p. 247—248°, pale yellow leaflets).   C. S.

Preparation of Morphine Esters of Halogenated Fatty Acids. CHEMISCHE FABRIK VON FRIEDR. HEYDEN (D.R.-P. 256156. Compare this vol., i, 385).—*Dichloroacetylmorphine*, a yellow powder, decomp. 204°, is obtained when cooled anhydrous morphine (5 parts) is slowly treated with chloroacetyl chloride (10 parts) and subsequently heated at 90—100°.

Chloroacetylmorphine, colourless crystals, decomp. 227°, is obtained by the partial hydrolysis of the preceding compound or by employing 6 parts of chloroacetyl chloride in the foregoing preparation. *Di-a-bromoisovalerylmorphine*, sintering at 61° and decomposing at 133°, is formed by the action of a-bromoisovaleryl chloride on morphine in the presence of pyridine.   F. M. G. M.

The Symmetry of Sparteine. LOUIS CORRIEZ (*Chem. Zentr.*, 1913, i, 29; from *Bull. Sci. Pharmacol.*, 1912, 19, 602—610. Compare Moureu and Valeur, A., 1912, i, 296).—An attempt to prove the symmetry of the sparteine molecule was made by decomposing the hydrochloride of a-sparteine methochloride and the hydrobromide of a-sparteine methobromide in a vacuum at 250°, but the reaction was of a complicated nature, since the resulting sparteine haloids partly decomposed into sparteine. An attempt to obtain the same iodobromide by treating sparteine iodide with hydrogen bromide and sparteine bromide with hydrogen iodide was also without success. A homogeneous, faintly yellow *iodobromide*, $C_{15}H_{26}N_2,HI,HBr,H_2O$, was obtained in the former case, in cubes with $[a]_D - 16°21'$, but the latter process led to a mixture, containing, in all probability, the dibromide, di-iodide, and iodobromide.   J. C. W.

Hæmopyrrole. OSKAR PILOTY and JOSEF STOCK (*Ber.*, 1913, 46, 1008—1013. Compare A., 1912, i, 923).—Crude hæmopyrrole has been separated into two fractions, the one, hæmopyrrole-I, consisting of a mixture of bases which give crystalline salts with picric acid in ethereal solution; the other, hæmopyrrole-II, comprising bases which

either do not form a picrate or of which the picrates are soluble in ether. The hæmopyrrole-II fraction comprises only 12—13% of the whole; it consists as to more than one-half of pyrroles with less than eight atoms of carbon, the remainder containing pyrroles with eight carbon atoms. It consists of at least three components differing from the five hæmopyrroles already known, and the lowest boiling fraction forms a very soluble, orange-coloured picrate, m. p. 108°, whilst a high boiling fraction closely resembles bis-dimethyl-pyrrole (Piloty and Wilke, A., 1912, i, 899). E. F. A.

Preparation of a Dichloroisatin [and of 5 : 7-Dichloroisatin]. FARBENFABRIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 255772 and 255774. Compare A., 1909, i, 966).—When an aqueous solution or suspension of isatin, or of 5-chloroisatin (m. p. 247°), is chlorinated at the ordinary temperature in the presence of potassium iodide, it gives rise to an unstable *dichloroisatin*, which crystallises from acetic acid in hard, red crystals, and has m. p. 155°; when this is dissolved in sodium hydrogen sulphite it loses chlorine, and the subsequent addition of acid precipitates 5-chloroisatin, whilst by the action of concentrated sulphuric acid at 80° in the presence of iodine the labile chlorine atom migrates into the ring, yielding 5 : 7-dichloroisatin (m. p. 221°).
F. M. G. M.

Preparation of a Dichlorobromoisatin. FARBENFABRIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 255773 and 255775. Compare preceding abstract).—When an aqueous suspension of 5-bromoisatin is treated at about 15° with chlorine in the presence of potassium iodide, it furnishes a *chloro-5-bromoisatin* (red prisms, m. p. 145°), in which the chlorine atom is labile and eliminated by the action of sodium hydrogen sulphite, whilst with concentrated sulphuric acid at 80° in the presence of potassium iodide it yields 7-*chloro-5-bromoisatin*, yellow needles, m. p. 231°. F. M. G. M.

Lepidylamine. PAUL RABE (*Ber.*, 1913, 46, 1024—1025).— 4-Cyanoquinoline is reduced, either on treatment with nascent hydrogen or on shaking with molecular hydrogen and a palladium sol, to 4-*aminomethylquinoline* (*lepidylamine*), $C_6H_4 < ^{C(CH_2 \cdot NH_2)}_{N ===CH} > CH$. This is a colourless oil, b. p. 172°/8 mm., but becomes violet on exposure to the air. The *monohydrochloride*, which is neutral to litmus, forms a colourless, crystalline powder, m. p. 206—208° (decomp.), which becomes blue on exposure to air. The *dihydrochloride* crystallises in well formed, colourless needles, decomp. above 250°. It is acid to litmus. E. F. A.

Quinolyl Ketones. I. PAUL RABE and RICHARD PASTERNACK (*Ber.*, 1913, 46, 1026—1032).—By the interaction of magnesium phenyl bromide and ethyl cinchonate under special conditions, phenyl 4-quinolyl ketone, m. p. 60°, is obtained. This differs from the compound, m. p. 294°, described under the same name by Remfry and Decker (A., 1908, i, 364). In addition to ketones the esters of quinoline-4-

carboxylic acid give rise to carbinols when submitted to the Grignard synthesis. Similarly, 4-cyanoquinolines give rise to ketones and amines ; thus 4-cyanoquinoline and magnesium ethyliodide yield 4-quinolyl ethyl ketone and 4-quinolyldiethylaminomethane. In addition some quantity of 4-ethylquinoline is formed.

4-Benzylquinoline is a viscid, strongly refractive, yellow oil, b. p. 222—223°/19 mm. ; the *sulphate* forms colourless, rhombic crystals + $2H_2O$, m. p. 105—108°, or anhydrous, m. p. 132—133°. The *picrate* forms yellow prisms and plates, m. p. 178° ; the *methiodide* crystallises in orange plates, m. p. 226°.

Phenyl 4-quinolyl ketone, m. p. 60°, yields the following salts : the picrate, crystallising in pale yellow, interlaced needles, m. p. 220° ; a *picrolonate*, forming dark yellow, rhombic crystals, decomp. 174° ; an orange *methiodide*, with metallic lustre, m. p. 218° ; an *oxime hydrochloride*, separating in matted needles, m. p. 256° (decomp.).

4-Quinolylethylketone is a yellow oil, b. p. 163—166°/8—9 mm. ; the *acetate* forms colourless needles, m. p. 87°. The *oximino*-derivative crystallises in short, colourless crystals, decomp. about 220°.

4-Quinolyldiethylcarbinol crystallises in lustrous, colourless plates, m. p. 135°, b. p. 192—198°/13 mm.

4-Quinolyldiethylaminomethane crystallises in colourless plates, m. p. 126°.   E. F. A.

Quinolyl Ketones. II. PAUL RABE and RICHARD PASTERNACK (*Ber.*, 1913, **46**, 1032—1034).—Ethyl quinolinecarboxylates in presence of sodium ethoxide condense with esters of the general constitution $R_1 \cdot CH_2 \cdot CO_2 R_2$; thus ethylcinchonate and ethylacetate combine to form *ethyl-γ-quinoloylacetate*, $\begin{matrix} N \cdot C_6 H_4 \\ CH \cdot CH \end{matrix} > C \cdot CO \cdot CH_2 \cdot CO_2$, a yellow oil, which could not be distilled unchanged, and is characterised by forming a sparingly soluble acid sulphate. When heated with 25% sulphuric acid, 4-quinolyl methyl ketone is obtained.

Similarly, ethyl quinate and ethyl propionate condense to form *ethyl β-[6-methoxy-4-quinoloyl]-propionate*. This is characterised by the *picrate* crystallising in slender, yellow needles, m. p. 137—138°, and the *picrolonate*, orange, matted needles, decomp. 136°.
β-6-Methoxyquinolyl ethyl ketone, obtained on hydrolysis, crystallises in pale yellow needles, m. p. 57—58°.   E. F. A.

Nature of Picolide and Pyrindole. Action of Propionic Acid on α-Picoline. MAX SCHOLTZ and W. FRAUDE (*Ber.*, 1913, **46**, 1069—1082. Compare A., 1912, i, 385, 648).—Derivatives of pyrrocoline have previously been prepared by Angeli (A., 1890, 1156), who termed the compound pyrindole, and this name is now adopted by the authors.
From the absence of basic properties and the formation of condensation products with only one molecule of phenylhydrazine, hydroxylamine, and semicarbazide, the conclusion is drawn that picolide contains one of its carbonyl groups directly attached to the nitrogen atom. This view is confirmed by the fact that towards alkyl

magnesium haloids, picolide behaves as a monoketone; it reacts with nly one molecule of the organo-magnesium compound, yielding tertiary alcohols of the formula $C_{10}H_8ON \cdot CMeR \cdot OH$.
The reactions of picolide and its transformation into pyrindole are best represented by the formula I, its formation from a-picoline being shown in the following scheme :

$$C_5H_4NMe \xrightarrow{Ac_2O} \begin{array}{l} CH{:}CH \cdot C{:}CH \cdot COMe \\ CH{:}CH \cdot N \cdot COMe \end{array} \xrightarrow{Ac_2O} H_2O +$$

$$(I.) \begin{array}{l} CH{:}CH \cdot C{:}C(COMe) \\ CH{:}CH \cdot N \cdot CO \text{---} CH \end{array}{>}CMe.$$

On account of its relationship to quinoline, the parent ring system (II) is termed quinolizine. Picolide is thus acetylmethylketoquinolizine, whilst the mono-nitro-compound obtained by the action of nitric acid is nitromethylketoquinolizine (III) :

$$(I\,I.) \begin{array}{l} CH{:}CH \cdot CH \cdot CH{:}CH \\ CH{:}CH \cdot N \text{---} CH{:}CH \end{array} \qquad (III.) \begin{array}{l} CH{:}CH \cdot C{:}C(NO_2) \cdot CMe \\ CH{:}CH \cdot N \text{---} CO \text{---} CH \end{array}.$$

Pyrindole couples with diazonium salts in acid solution, yielding crystalline azo-compounds, and reacts with acetic anhydride and benzoyl chloride to form an acetyl and benzoyl derivative. The position of the azo- and acyl-groups has not been definitely established, but from the analogous reactions with pyrrole it is assumed that the groups enter the a-position to the pyrrole ring; benzene-azopyrindole thus receives the formula :

$$(IV.) \begin{array}{l} CH{:}CH \cdot C{:}CH \\ CH{:}CH \cdot N \text{---} C \end{array}{>}\!{<}^{CH}_{} N{:}NPh.$$

A number of other reactions, illustrating the similarity in the behaviour of pyrindole on the one hand and pyrrole and indole derivatives on the other, are also described.

The ready formation of picolide from a-picoline and acetic anhydride has induced the authors to investigate the behaviour of a-picoline towards other anhydrides, but only in the case of propionic anhydride could a definite product be isolated. The reaction proceeds in a manner entirely different to that occurring when acetic anhydride is employed, the resulting compound being a 2-pyridyl-3-ethyl-Δ^3-*cyclo*pentenone :

$$(V.)\ CH{<}^{CH{:}CH}_{CH \text{---} N}{>}C \cdot CH{<}^{CO \text{---} CH_2}_{OEt{:}CH}.$$
The following condensation products were obtained by condensing aromatic aldehydes with picolide by means of sodium hydroxide in alcoholic solution :

Di-o-nitrobenzylidenepicolide, yellowish-brown crystals, which begin to decompose at 200°, m. p. 220°; the isomeric *meta-* and *para-* compounds have m. p. 212° and 316° respectively; *mono-p-nitrobenzylidenepicolide*, orange needles, m. p. 242°; *tetramethyldi-p-aminobenzylidenepicolide*, from *p*-dimethylaminobenzaldehyde, forms orange needles, m. p. 227°; *dianisylidenepicolide*, m. p. 212°.

Picolide reacts with magnesium methyl iodide to form the *compound,* $C_{10}H_8NO \cdot CMe_2 \cdot OH$, crystallising in long, yellow needles, m. p. 169°,

and with magnesium phenyl bromide, yielding the *compound*,

$$C_{10}H_8ON \cdot CMePh \cdot OH,$$
which forms colourless, felted needles, m. p. 178°.

Benzeneazopyrindole (formula IV) crystallises in red needles, m. p. 109°, and *pyrindoleazo-p-toluene* in reddish-brown needles, m. p. 98°.

α-*Naphthaleneazopyrindole* forms a brown, crystalline powder, which begins to melt at 120° and then decomposes.

Benzoylpyrindole, $C_8H_6N \cdot COPh$, prepared by the interaction of pyrindole and benzoyl chloride at the ordinary temperature, crystallises in yellow needles, m. p. 96°.

Pyrindole reacts with carbonyl chloride in toluene solution to form *pyrindolecarboxyl chloride*, $C_8H_6N \cdot COCl$, which crystallises in colourless needles, m. p. 81°, and is hydrolysed by aqueous sodium hydroxide to *pyrindolecarboxylic acid*, needles, m. p. 135° (decomp.).
Diquinonylpyrindole,
$$\begin{array}{c} CH{:}CH \cdot C{=\!=\!=}C \cdot C_6H_4O_2 \\ CH{:}CH \cdot N \cdot CH{:}C \cdot C_6H_4O_2 \end{array},$$
prepared from pyrindole and quinone in alcoholic solution, forms deep blue crystals, m. p. above 350°, and resembles the diquinonyldimethylpyrrole described by Möhlau and Redlich (A., 1912, i, 129°).

Pyrindole condenses with ethyl acetoacetate in alcoholic solution in the presence of hydrochloric acid, yielding *ethyl dipyrindoleacetoacetate*,
$$\begin{array}{c} CH{:}CH \cdot C{=\!=\!=}C \cdot CMe(CH_2 \cdot CO_2Et) \cdot C{=\!=\!=}C \cdot CH{:}CH \\ CH{:}CH \cdot N \cdot CH{:}C \cdot OMe(CH_2 \cdot CO_2Et) \cdot C{:}CH \cdot N \cdot CH{:}CH \end{array},$$
crystallising in microscopic, yellowish-green needles, m. p. 140°.

2-*Pyridyl*-3-*ethyl*-Δ³-*cyclopentenone* (V), prepared by heating α-picoline and propionic anhydride at 220°, forms colourless needles, m. p. 86°, and yields a *semicarbazone*, yellow needles, m. p. 201°.   F. B.

**Preparation of Methylolcarbazole.** MARTIN LANGE (D.R.-P. 256757).—*Methylolcarbazole* (annexed formula) is obtained when a boiling alcoholic solution of carbazole (16·7 parts) is treated with anhydrous potassium carbonate (10 parts) and a 40% solution of formaldehyde (10 parts); on cooling, the product separates; it forms colourless needles, m. p. 127—128°, with an evolution of formaldehyde; mineral acids convert it into methylenecarbazole.   F. M. G. M.

Preparation of N-Alkylcarbazolesulphonic Acids. LEOPOLD CASSELLA & Co. (D.R.-P. 256718. Compare A., 1910, i, 775).— Sulphonated N-alkylcarbazoles have not been prepared, although di- and tri-sulphonyl derivatives of carbazole itself are known. *Ethyl carbazolesulphonic acid* is obtained when fused N-ethylcarbazole (195 parts) is slowly treated with forty parts of concentrated sulphuric acid, heated at 120° and subsequently at 150—160°, and the mixture finally treated with sodium carbonate; the *barium*, *calcium*, *sodium*, and *potassium* salts are crystalline powders.

When fused with an alkali hydroxide, these compounds furnish hydroxy-N-alkylcarbazoles, which condense with p-nitrosophenols to yield indophenolsulphonic acids.   F. M. G. M.
Ammonium-amides and the Action of Amines on Cyclammonium Salts and Analogous Compounds. HERMAN DECKER and PAUL BECKER (*Ber.*, 1913, **46**, 969—978).—It has already been shown that the action of ammonia or amines on the quaternary salts of phenylacridinecarboxylic acid yields not only the lactone, but also the lactam of aminophenylmethyldihydroacridinecarboxylic acid (Decker and Schenk, A., 1906, i, 304), and it was suggested that the change takes place with the intermediate formation of a compound corresponding to ammonium-amide, $NH_4 \cdot NH_2$, the scheme :

$$NMeI \underset{C_6H_4}{\overset{C_6H_4}{<}} C \cdot C_6H_4 \cdot CO_2H \rightarrow NH_2 \cdot NMe \underset{C_6H_4}{\overset{C_6H_4}{<}} C \cdot C_6H_4 \cdot CO_2H$$

$$NMe \underset{C_6H_4}{\overset{C_6H_4}{<}} C \underset{C_6H_4}{\overset{NH-}{<}} CO \leftarrow NMe \underset{C_6H_4}{\overset{C_6H_4}{<}} C(NH_2) \cdot C_6H_4 \cdot CO_2H$$

representing the probable series of changes. This view was confirmed by several considerations, and it is now greatly strengthened by the discovery that the parent substance, phenylacridine methiodide, is converted by concentrated ammonia into 5-amino-5-phenyl-10-methyldihydroacridine, $NMe \underset{C_6H_4}{\overset{C_6H_4}{<}} CPh \cdot NH_2$. This finally disposes of any idea that the previous product may have been due to the action of ammonia on the previously formed lactone. The cause of the rearrangement is supposed to be the tendency of the positive amino-group to migrate from the positive nitrogen atom to a negative carbon atom. That such a substance as $NH_2 \cdot NMe \underset{C_6H_4}{\overset{C_6H_4}{<}} CPh$, which is assumed as the first product of the above reaction, should be capable of at least a fleeting existence is indicated by the formation of carbinylamines by the action of ammonia on the salts of the triphenylmethane dyes, in which the analogous steps :

$$(NH_2 \cdot C_6H_4)_2 \cdot C \colon C_6H_4 \colon NH_2Cl \rightarrow (NH_2 \cdot C_6H_4)_2 C \colon C_6H_4 \colon NH_2 \cdot NH_2 \rightarrow$$
$$(NH_2 \cdot C_6H_4)_2 C(NH_2) \cdot C_6H_4 \cdot NH_2$$

probably occur (Noelting and Saas, this vol., i, 522; Villiger and Kopetschni, A., 1912, i, 1030). The structurally related xanthylium and thioxanthylium salts also yield carbinylamines with ammonia. The possibility, that the acridinium salts may be of the carbonium structure which has been suggested for the triphenylmethane colours is very slight, as the former eliminate methyl iodide exceedingly readily, even, for example, when exposed in aqueous solution to daylight for several weeks.

5-Amino-5-phenyl-10-methyldihydroacridine, small, colourless rods, m. p. 121—122°, is obtained by the gradual addition of a concentrated solution of phenylacridine methiodide to a large excess of 20% ammonia solution ; if a dilute solution of ammonia in slight excess is allowed to act on the methiodide, the product is hydroxyphenylmethyldihydroacridine, which is ver similar in appearance, and this accounts for the divergence of the results of Decker, Hock, and Djiwonsky (A., 1902,

i, 830) and of Hantzsch (A., 1902, i, 113, 126). The above amino-compound dissolves in dilute acids, undergoing scission into phenyl-methylacridinium and ammonium salts; when heated with alcohol, with or without the addition of a little sodium hydroxide, ammonia is again obtained, together with the 5-ethoxy-5-phenyl-10-methyldihydro-acridine, colourless prisms, m. p. 112—113°, which is also obtained by similar treatment of the hydroxyphenylmethyldihydroacridine itself. When warmed with aniline, both the above amino-compound (a carbinylamine) and the corresponding hydroxy-compound are converted into the *carbinylanilide* with elimination of a molecule of ammonia and of water respectively.

If a solution of a phenylxanthylium salt is introduced into ammonia solution a mixture of the amino-compound and of the carbinol is obtained (compare Bunzly and Decker, A., 1904, i, 912); for the preparation of the pure amino compound the phenylxanthylium ferri-chloride, m. p. 169°, was introduced as a fine powder into 20% ammonia solution under benzene; the resultant carbinylamine (9-*amino*-9-*phenyl-xanthen*), $O<^{C_6H_4}_{C_6H_4}>CPh\cdot NH_2$, leaflets, m. p. 112—113°, is extracted by the benzene; when boiled with alcohol it is converted into the ethyl ether of phenylxanthenol (Bünzly and Decker, *loc. cit.*). The formation of the carbinylamine is believed to follow the same course as with the corresponding acridine compound.

9-*Amino*-9-*phenylthioxanthen*, yellowish-red prisms, m. p. 118—120°, is obtained in a similar manner by the action of ammonia on phenyl-thioxanthylium ferrichloride, and undergoes similar conversion into the ethyl ether of thioxanthenol.

The recent discovery of Zincke and Weisspfennig (this vol., i, 389) of dinitrodiphenylamine amongst the reaction products of aniline and 2-dinitrophenyl*iso*quinolinium chloride is held to be a further confirma-tion of the existence of the ammonium-amides and of their decomposi-tion according to the equation: $NA_4\cdot NR_2 = NA_3 + NR_2A$, where A represents an alkyl radicle.   D. F. T.

Preparation of Anthracene Derivatives Containing Nitrogen.
FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 256297. Compare A., 1908, i, 456, 699; 1909, i, 263).—α-*Chloropyridanthrone*, yellowish-white needles, m. p. 260°, is prepared by the action of phosphorus pentachloride on the previously described 2-hydroxy-pyridanthrone (I); it reacts readily with primary aromatic amines to furnish compounds of the general formula (II).

(I.)   (II.)
2(1')-*Anthraquinonylaminopyridanthrone* is thus obtained by condensation with 1-aminoanthraquinone in nitrobenzene solution in the presence of copper iodide and sodium acetate ; it does not melt below 300°. The analogous *compound* from aniline has m. p. 227—229°.

<div align="right">F. M. G. M.</div>

Syntheses in the Group of the Indogenides. ANDRÉ WAHL and P. BAGARD (*Compt. rend.*, 1913, **156**, 898—901).—An endeavour to prepare, by the condensation of substituted isatins with oxindole, a new series of indogenides of the type $X<^{C_6H_3R}_{CO}>C:C<^{C_6H_3R'}_{CO}>Y$, where X and Y may be identical or different bivalent atoms or groups, and R and R' any substituents. These condensations did not, however, go so simply as in the case of isatin itself and oxindole (compare A., 1909, i, 330). Thioisatin and oxindole yields not thio-3 . 3'-bisindole, as expected, but "thioindigo scarlet," $NH<^{C_6H_4}_{CO}>C:C<^{CO}_{S}>C_6H_4$ (compare Kalle, D R -P. 241327). 1-Methylisatin on the other hand behaves like isatin itself, and gives 1-*methyl*iso*indigotin*,

$$NH<^{C_6H_4}_{CO}>C:C<^{C_6H_4}_{CO}>NMe,$$
brown needles.

2-Methylisatin when mixed with oxindole in acetic acid solution containing a little aqueous hydrochloric acid is hydrolysed and the product of condensation is simply 3 : 3'-bisindole. If the action takes place in an anhydrous medium in the cold, indirubin is formed. This thus furnishes an easy and rapid method of preparing indirubin, and gives a 90% yield.

<div align="right">W. G.</div>

[**Preparation of 1-Chloronitro-2 : 4-diacetylphenylenediamine.**] AKTIEN-GESELLSCHAFT FUR ANILINFABRIKATION (D.R.-P. 255858).—1-Chloro-2 : 4-phenylenediamine gives rise to a diacetyl derivative which on nitration furnishes 1-*chloronitro* 2 : 4-*diacetylphenylenediamine*, m. p. 234—235°, and on hydrolysis yields 1-*chloronitro*-2 : 4-*phenylenediamine*, m. p. 170°.

Existence of Phenyldi-imide. WILHELM VAUBEL (*Ber.*, 1913, **46**, 1115—1116. Compare A , 1900, i, 522) —An acknowledgment of the criticism of Forster and Withers (T., 1913, **103**, 266) as to the nature of the compound described as phenyldi-imide.

<div align="right">H. W.</div>

[**Preparation of Anthraquinone Derivatives**] FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 256626).—3-*Bromo-4-amino-anthraquinoneacridone*, a blue powder, m. p. 260—270°, is obtained when 3-bromo-4-amino-1-anthraquinonylanthranilic acid is heated at 30° with chlorosulphonic acid.

<div align="right">F. M. G. M.</div>

[**Preparation of Indigoid Compounds.**] BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 255691. Compare A., 1906, i, 696).—The *compound*, $C_6H_4<^{NH}_{CO}>C:C<^{CH}_{C_6H_4}>N$, dark red needles, m. p. 212°

<div align="right">*n n* 2</div>

(decomp.), is obtained by the action of alkali hydroxides on indoxyl; if the action is allowed to proceed further, it gives rise to the *compound*, $C_6H_4\text{<}^{NH-}_{CO_2H}\text{>}CH:C\text{<}^{CH}_{C_6H_4}\text{>}N$, and this, when boiled with an alkali carbonate, furnishes anthranilic acid and β-indolealdehyde (*loc. cit.*).   F. M. G. M.

Action of Aliphatic Ketones on Indole and its Homologues : Polymeric Indoles. MAX SCHOLTZ (*Ber.*, 1913, **46**, 1082—1089).— Indole and its 2-methyl derivative condense with acetone, yielding compounds of the type: (I) $N\text{<}^{C_6H_4}_{CH}\text{>}C\text{<}^{CMe_2}_{CMe_2}\text{>}C\text{<}^{C_6H_4}_{CH}\text{>}N$ and

(II) $NH\text{<}^{C_6H_4}_{CH}\text{>}C\cdot CMe_2\cdot C\text{<}^{C_6H_4}_{CH}\text{>}NH$, accordingly as the condensation is effected by means of hydrochloric acid or acetic acid. Similar products are obtained from methyl ethyl ketone, but not from diethyl ketone.

Bisdimethyl-2-methylindolidenemethane,

$$C_8H_4NMe\text{<}^{CMe_2}_{CMe_2}\text{>}C_8H_4NMe,$$
obtained in the form of its *hydrochloride* (colourless needles, m. p. 172°) by the addition of hydrochloric acid to an alcoholic solution of 2-methylindole and acetone, crystallises in colourless needles, m. p. 183°; the *hydrobromide*, prepared in a similar manner, has m. p. 172°.

Bis-2-methylindyldimethylmethane, $CMe_2(C_8H_5NMe)_2$, is obtained by boiling 2-methylindole with glacial acetic acid; it crystallises in colourless leaflets, m. p. 197°.

Bismethylethyl-2-methylindolidenemethane,

$$C_8H_4NMe\text{<}^{CMeEt}_{CMeEt}\text{>}C_8H_4NMe,$$
prepared from methyl ethyl ketone, using hydrochloric acid as the condensing agent, forms colourless leaflets, m. p. 97°; the *hydrochloride* crystallises in colourless needles, m. p. 166°.

Ethyl acetoacetate and 2-methylindole yield *ethyl 2-methylindolideneacetoacetate*, $N\text{<}^{C_6H_4}_{CMe}\text{>}C:CMe\cdot CH_2\cdot CO_2Et$, crystallising in long, colourless needles, m. p. 124°.

Bisdimethylindolidenemethane (formula I), prepared from indole and acetone, forms light yellow needles, m. p. 170°; the *hydrochloride* crystallises in orange-yellow needles, m. p. 169°.

Bisindyldimethylmethane (II) forms colourless prisms, m. p. 165°.

An alcoholic solution of indole, on treatment with hydrochloric acid at the ordinary temperature, yields the *hydrochloride* of tri-indole, crystallising in prisms, m. p. 183°; replacement of the hydrochloric acid by hydrobromic acid gives rise to the *hydrobromide* of di-indole, which forms slender, colourless needles (compare Keller, this vol., i, 403).   F. B.

The Constitution of the Pyrazolinecarboxylic Acids. III. AUGUST DARAPSKY (*Ber.*, 1913, **46**, 863—867).—An experimental

investigation in favour of the view that the condensation products of the esters of the diazo-aliphatic acids with the esters of unsaturated carboxylic acids are in reality pyrazoline derivatives and not azine compounds with open-chain structure (compare Darapsky, this vol., i, 297; A., 1912, i, 391; Bülow, this vol., i, 101; A., 1912, i, 134, 316).

The reduction of 4-phenylpyrazole-3 : 5-dicarboxylic acid by sodium amalgam and water at 80—90° gave the same 4-phenylpyrazolidine-3 : 5-dicarboxylic acid (Buchner and Perkel, A., 1904, i, 101) as was obtained by a similar reduction of 4-phenylpyrazoline-3 : 5-dicarboxylic acid. The temperature of decomposition of the product ranges between 220° and 226° according to the rate of heating. D. F. T.

Constitution of Hypnal. DEMETRIUS E. TSAKALOTOS (*Bull. Soc. chim.*, 1913, [iv], 13, 281—285).—Béhal and Choay (A., 1893, i, 301) have obtained two substances by the action of chloral on antipyrine, to which they assign the formulæ below, the first of which is used in

$$
\begin{array}{ll}
\text{CH—CO} & \text{CH—CO} \\
\| \quad \text{>NPh} & \| \quad \text{>NPh(OH)·CH(OH)·CCl}_3 \\
\text{CMe·NMe(OH)·CH(OH)·CCl}_3 & \text{CMe·NMe(OH)·CH(OH)·CCl}_3 \\
\quad \text{(I.)} & \quad \text{(II.)}
\end{array}
$$
pharmacy under the name hypnal. For the second, the author proposes the name bihypnal. The substances have m. p. 62·3° and 61·8° respectively, whereas Béhal and Choay found 67—68° for either substance.

The author has examined the freezing-point curve of mixtures of chloral hydrate and antipyrine, and finds that it rises to a maximum at the two points at which chloral hydrate : antipyrine = 2 : 1 and = 1 : 1 respectively. From the general form of the curve, he is led to the conclusion that hypnal and bihypnal are molecular compounds, which, he considers, explains the practical identity of their m. p.'s

H. W.

Some New Derivatives of Piperazine. MARIO GHIGLIENO (*Atti R. Accad. Sci. Torino*, 1912–13, 48, 534—538).—When cyanacetic ester and anhydrous piperazine are heated together for one hour at 100—115°, *biscyanoacetylpiperazine*, $C_4H_8N_2(CO·CH_2·CN)_2$, is formed; it crystallises in colourless or slightly yellow needles, m. p. 248—250° (decomp.). When ordinary hydrated piperazine is used in the reaction, the corresponding *amide*, $C_4H_8N_2(CO·CH_2·CO·NH_2)_2$, is obtained; it crystallises in colourless needles or in prisms, which decompose about 174—175° when rapidly heated. The substance is acid in reaction, and gives metallic salts. It is converted into the dicarboxylic acid only with great difficulty. Anhydrous piperazine, m. p. 104°, is obtained by keeping ordinary piperazine over calcium chloride for a long time. R. V. S.

Pyrimidines. LX. Alkylation with Benzyl Chloride. TREAT B. JOHNSON and ZAI ZIANG ZEE (*Amer. Chem. J.*, 1913, 49, 287—294). —Johnson and Derby (A., 1908, i, 1018) studied the action of benzyl chloride in presence of sodium ethoxide on certain derivatives

of 2-ethylthiol-6-pyrimidone, and found that in all cases the corresponding *N*-benzyl compounds were produced. It was shown that the substitution of a methyl group in the 4- or 5-position and a bromine atom or ethoxy-group in the 5-position of the ring does not favour the formation of 6-benzoxypyrimidines. The present work was undertaken with the object of investigating the action of benzyl chloride on a 2-thiol-6-pyrimidone in which both the 4- and 5-positions are substituted, and of determining whether a strongly negative group in the 4-position would favour the production of an *O*-benzyl derivative.

Ethyl 2-amino-5-methyl-6-pyrimidone-4-carboxylate,

$$NH<\begin{array}{c}C(NH_2){:}N\\CO{-}CMe\end{array}>C{\cdot}CO_2Et,$$
obtained in small yield by the action of the sodium salt of ethyl oxalylpropionate on guanidine thiocyanate in presence of sodium hydroxide, forms prismatic needles, and does not show a definite m. p.

Ethyl 2-ethylthiol-1-benzyl-5-methyl-6-pyrimidone-4-carboxylate,

$$CH_2Ph{\cdot}N<\begin{array}{c}C(SEt){:}N\\CO{-}CMe\end{array}>C{\cdot}CO_2Et,$$
m. p. 69—71°, prepared by heating ethyl 2-ethylthiol-5-methyl-6-pyrimidone-5-carboxylate with benzyl chloride in presence of sodium ethoxide, crystallises in colourless needles, and when hydrolysed with concentrated hydrochloric acid is converted into 1-*benzyl-5-methyl-pyrimid-2 : 6-dione-4-carboxylic acid,*

$$CH_2Ph{\cdot}N<\begin{array}{c}CO{-}NH\\CO{\cdot}CMe\end{array}>C{\cdot}CO_2H,$$

m. p. 277—279° (decomp.), which forms hexagonal tablets. When the latter compound is heated at 285—295° until effervescence ceases, 1-*benzyl-5-methylpyrimid-2 : 6-dione* (1-*benzylthymine*),

$$CH_2Ph{\cdot}N<\begin{array}{c}CO{-}NH\\CO{\cdot}CMe\end{array}>CH,$$
m. p. 203—205°, is obtained, which forms prismatic crystals.

An attempt was made to alkylate ethyl 5-methylpyrimid-2 : 6-dione-4-carboxylate with benzyl chloride in presence of sodium ethoxide, but without success.   E. G.

[Phenazine] Correction. FRIEDRICH KEHRMANN (*Ber.*. 1913, **46**, 1220. Compare this vol., i, 298).—Fischer and Hepp (A., 1897, i, 257) had already observed that rosindones resulted by the action of alkalis on alkylnaphthaphenazonium salts. The author still holds that the green methylphenazonium iodide is a quinhydrone salt (compare Hantzsch, this vol., i, 393.)   J. C. W.

The Triphenylmethane Colour Bases. EMILIO NOELTING and J. SAAS (*Ber.*, 1913, **46**, 952—967).—The authors have convinced themselves that the action of ammonia on triphenylmethane dyes is, as was believed by von Baeyer (A., 1910, i, 249), more complex than was at first supposed (Noelting & Philipp, A., 1908, i, 295). An independent investigation of the products of the action of ammonia has been recently published by Villiger and Kopetschni (A., 1912, i, 1030).

Commercial crystal-violet always contains some of the pentamethyl compound, which can be detected by acetylation, dissolving in water, and partly immersing in the liquid a piece of filter paper ; the green colour of the acetyl derivative of the pentamethyl compound rises in the paper more rapidly than the violet. Even when Michler's ketone is condensed with pure dimethylaniline in the presence of phosphoryl chloride, the condensation product contains a quantity of pentamethyl compound. The product contains least pentamethyl compound if a large excess of the amine is taken for the condensation. The colourless substance obtained from the action of ammonia on crystal-violet is the carbinylamine, $NH_2 \cdot C(C_6H_4 \cdot NMe_2)_3$; it separates from a mixture of benzene and ligroin in prismatic tablets, m. p. 193—195°. The action of diethylamine on a solution of crystal-violet, on the other hand, precipitates the carbinol, m. p. 194—195°, which after recrystallisation has m. p. 207—209° (compare Villiger and Kopetschni, *loc. cit.*), whilst trimethylamine solution produces at first a violet solution of the ammonium base, $OH \cdot NMe_2 \cdot C_6H_4(C_6H_4 \cdot NMe_2)_2$, which shortly begins to lose its colour and to deposit the carbinol in a pure state.

Ethyl-violet (hexaethyltriaminotriphenylcarbinol), obtained from tetraethyldiaminobenzophenone, diethylaniline and phosphoryl chloride alone, or mixed with benzene at 100°, on precipitation with potassium hydroxide yielded the free colourless carbinol, $OH \cdot C(C_6H_4 \cdot NEt_2)_3$, m. p. 136—137°. When recrystallised from alcohol, the carbinol undergoes partial etherification, and the *ethyl ether*, $OEt \cdot C(C_6H_4 \cdot NEt_2)_3$, m. p. 127—128°, can be readily obtained by the action of sodium ethoxide. The *carbinylamine*, $NH_2 \cdot C(C_6H_4 \cdot NEt_2)_3$, of ethyl-violet forms colourless needles, m. p. 141·5—142·5°.

Victoria-Blue *B*, obtained by purification of the commercial article and by condensation of pure Michler's ketone with phenyl-α-naphthylamine, forms deep blue tablets, m. p. 247—249°. No corresponding carbinol, carbinyl ether and amine were isolable, as the action of alkalis yielded only an *imine* base, $NPh \cdot C_{10}H_6 \cdot C(C_6H_4 \cdot NMe_2)_2$, deep violet, prismatic tablets, which is hydrolysed by dilute sulphuric acid to Michler's ketone and phenyl-α-naphthylamine (compare Nathanson and Müller, A., 1889, 1188).

Night-Blue, m. p. 219—220°, yields an analogous *imine* base,

$$C_6H_4Me \cdot N \cdot C_{10}H_6 \cdot C(C_6H_4 \cdot NMe_2)_2,$$

deep violet, prismatic tablets, which can also be hydrolysed to its components, Michler's ketone, and tolyl-α-naphthylamine.

α-Naphthol-Blue (tetramethyldiaminonaphthafuchsone), the condensation product of Michler's ketone, and α-naphthol, when pure, forms dark-coloured prisms, m. p. 266—270°; *hydrochloride*, green needles ; *platinichloride*, dark coloured. No carbinol, carbinyl ether, or carbinylamine could be isolated ; it gives a green *acetyl* derivative, and on reduction in acetic acid by zinc dust a *leuco-base*,

$$OH(C_6H_4 \cdot NMe_2)_2 \cdot C_{10}H_6 \cdot OH,$$

prisms, m. p. 187—188°.

Naphtho-Blue (Noelting and Philipp, *loc. cit.*), the condensation product of Michler's ketone and dimethyl-α-naphthylamine, can be separated into a coloured and a colourless constituent ; the latter is, as

earlier suggested, the carbinol, $OH \cdot C(C_6H_4 \cdot NMe_2)_2 \cdot C_{10}H_6 \cdot NMe_2$, but the former is actually identical with α-Naphthol-Blue, and must be produced by a partial elimination of dimethylamine during the neutralisation of the reaction product; the product also always contains some pentamethyl compound, $C(C_6H_4 \cdot NMe_2)_2 \cdot C_6H_4 \cdot NMe,HCe$, due to a loss of a methyl group similar to that observed in the preparation of crystal-violet. For the preparation of the pure colourless carbinol of Naphtho-Blue it is advisable to use in the condensation an excess of dimethyl-α-naphthylamine, and then to render the solution of the product alkaline at as low a temperature as possible. Treatment of the aqueous solution of the chloride with ammonia yields the colourless carbinylamine, m. p. 173—175°.   D. F. T.

5-Aminopyrazole and Iminopyrines. III. 5-Imino-1-phenyl-3-methylpyrazolone. AUGUST MICHAELIS and ARTHUR SCHÄFER (*Annalen.*, 1913, **397**, 119—148. Compare A., 1911, i, 1037; 1905, i, 476).—*1-Phenyl-3-methyl-4 : 5-azipyrazole,* $N{<}^{NPh \cdot C}_{CMe \cdot CH}{>}N$, m. p. 109°, yellowish-brown leaflets, prepared by warming 5-amino-1-phenyl-3-methylpyrazole (5-imino-1-phenyl-3-methylpyrazolone) in 50% acetic acid with concentrated hydrogen peroxide, is converted into 5-amino-1-phenyl-3-methylpyrazole by reducing agents and into 4-halogeno-5-amino-1-phenyl-3-methylpyrazoles by warming with concentrated halogen acids. *4-Chloro-1-phenyl-3-methyl-4 : 5-azipyrazole,* m. p. 103°, red leaflets, is obtained by treating 4-chloro-5-amino-1-phenyl-3-methylpyrazole with hydrogen peroxide as above, or, in hydrochloric acid, with concentrated sodium nitrite. It is also obtained by leading chlorine into a hydrochloric acid solution of 5-amino-1-phenyl-3-methylpyrazole. The last method has enabled the authors to explain the constitution of the trichloro-compound obtained by Michaelis and Brust (*loc. cit.*); this is not 4-chloro-5-amino-1-dichlorophenyl-3-methylpyrazole as stated previously, but *4-chloro-5-dichloroamino-1-phenyl-3-methylpyrazole,* m. p. 60°, since it yields 4-chloro-1-phenyl-3-methyl-4 : 5-azipyrazole by warming with water. Unlike the non-halogenated compound, 4-chloro-1-phenyl-3-methyl-4 : 5-azipyrazole is unchanged by halogen acids; it is reduced to 4-chloro-5-amino-1-phenyl-3-methylpyrazole by boiling concentrated sodium hyposulphite. *4-Bromo-1-phenyl-3-methyl-4 : 5-azipyrazole,* $C_{10}H_8N_3Br$, m. p. 101°, reddish-brown leaflets, prepared by similar methods to the chloro-compound, yields 4-bromo-5-amino-1-phenyl-3-methylpyrazole by reduction, and is converted into *4 : 4-dibromo-5-imino-1-phenyl-3-methylpyrazolone,*

$$NPh{<}^{N=\!=\!=CMe}_{C(:NH) \cdot CBr_2},$$
m. p. 126°, colourless needles, and *4-chloro-4-bromo-5-imino-1-phenyl-3-methylpyrazolone,* m. p. 124°, colourless needles, by warming with hydrobromic acid or hydrochloric acid, and subsequently basifying with ammonia. *4-Iodo-1-phenyl-3-methyl-4 : 5-azipyrazole,* $C_{10}H_8N_3I$, m. p. 194°, yellowish-red needles, prepared by the oxidation of 4-iodo-5-amino-1-phenyl-3-methylpyrazole or by heating 5-amino-1-phenyl-3-methylpyrazole with alcoholic iodine and sodium hydroxide at 150°, is

unchanged by halogen acids, and is converted into 4-iodo-5-amino-1-phenyl-3-methylpyrazole by reduction. 1-*Phenyl*-3 : 4-*dimethyl*-4 : 5-*azipyrazole*, $C_{11}H_{11}N_3$, m. p. 105°, red leaflets, is prepared by oxidising 5-amino-1-phenyl-3 : 4-dimethylpyrazole in hydrochloric acid by hydrogen peroxide; it is soluble in concentrated halogen acids and is precipitated unchanged by alkalis. 4 : 5-*Anilo-1-phenyl-3-methylpyrazole*,

$$N\!\!<^{\text{NPh}\cdot\text{C}}_{\text{CMe}\cdot\text{C}}\!\!\!\!>\!\!NPh,$$

m. p. 169°, red leaflets or brownish-red needles, is prepared by treating a glacial acetic acid solution of 4-benzeneazo-5-amino-1-phenyl-3-methylpyrazole with concentrated sodium nitrite, whereby nitrogen and nitric oxide are evolved. By reduction with tin and alcoholic hydrochloric acid, it yields benzene and 4-amino-1-phenyl-3-methyl-5-pyrazolone hydrochloride, by the oxidation of which in the air rubazonic acid is produced. 4-β-*Naphthaleneazo-5-amino-1-phenyl-3-methylpyrazole*, $C_{20}H_{17}N_5$, m. p. 117°, yellow leaflets, prepared from β-naphthalenediazonium chloride and 5-amino-1-phenyl-3-methylpyrazole in aqueous sodium carbonate, is converted in a similar manner into 4 : 5-β-*naphthylimino-1-phenyl 3-methylpyrazole*, $C_{20}H_{15}N_3$, m. p. 178°, reddish-brown needles, by the reduction of which naphthalene and 4-amino-1-phenyl-3-methylpyrazole are formed.

5-*Formylamino-1-phenyl-3-methylpyrazole*, $C_{11}H_{11}ON_3$, m. p. 135°, colourless needles, prepared from the aminopyrazole and formic acid on the water-bath, and the corresponding *benzoylamino*-derivative, $C_{17}H_{15}ON_3$, m. p. 113°, long needles, have been prepared; the latter is converted into 4 *bromo-5-benzoylamino-1-phenyl-3-methylpyrazole*, m. p. 172°, by bromine in dilute acetic acid. 5-*Benzenesulphonylamino-1-phenyl-3-methylpyrazole* has m. p. 170°. 5-Acetylamino-1-phenyl-3-methylpyrazole and benzenediazonium chloride yield a *substance*,

$$C_{39}H_{41}O_4N_7,$$
m. p. 107°, yellow needles, which is being investigated.

Hot aqueous potassium cyanate and 5-amino-1-phenyl-3-methyl-pyrazole hydrochloride yield 5-*carbamido-1-phenyl-3-methylpyrazole*,

$$NH_2\cdot CO\cdot NH\cdot C\!\!<^{\text{NPh}\cdot\text{N}}_{\text{CH}-\text{CMe}},$$

m. p. 215°, colourless needles.

5-Amino-1-phenyl-3-methylpyrazole and phenylcarbimide yield, by heating, 5-*phenylcarbamido-1-phenyl-3-methylpyrazole*, m. p. 205°; the *phenylthiocarbamido*-derivative, m. p. 150°, is prepared in a similar manner. The 5-aminopyrazole and carbon disulphide at 150° yield the s-*thiocarbamide*, $CS(NH\cdot C_{10}H_9N_2)_2$, m. p. 184°.

5-Amino-1-phenyl-3-methylpyrazole can be almost completely diazotised in nearly concentrated hydrochloric acid (compare Mohr, A., 1909, i, 190); the solution does not contain 4-oximino-5-imino-1-phenyl-3-methylpyrazolone, and yields coloured precipitates with alkaline β-naphthol and resorcinol. 1-*Phenyl-3-methylpyrazole-5-azoresorcinol*, $C_{16}H_{14}O_2N_4$, yellow needles, has m. p. 250°. 1-Phenyl-3-methyl-pyrazole-5-diazonium chloride and 1-phenyl-3-methyl-5-pyrazolone in acetic acid slowly form 1-*phenyl-3-methylpyrazole-5(4')-azo-1'-phenyl-3'-methyl-5'-pyrazolone*,

$$^{\text{N}-\text{NPh}}_{\text{CMe}\cdot\text{CH}}\!\!>\!\!C\cdot N_2\cdot CH\!\!<^{\text{CO}-\text{NPh}}_{\text{CMe:N}},$$

m. p. 175°, yellowish-red needles, which is soluble in alkalis. 5-*Diazoamino-*

1-*phenyl*-3-*methylpyrazole*, $C_{10}N_2H_9 \cdot N_2 \cdot NH \cdot C_{10}N_2H_9$, m. p. 182°, yellow leaflets, is obtained by treating 5-amino-1-phenyl-3-methylpyrazole in hydrochloric acid with less than 1 mol. of sodium nitrite, or by carefully treating the completely diazotised solution with aqueous sodium hydroxide.

5-Amino-1-phenyl-3-methylpyrazole and benzaldehyde at 135° yield 4-*benzylidenebis*-5-*amino*-1-*phenyl*-3-*methylpyrazole*, $CHPh(C_{10}N_3H_{10})_2$, m. p. 66°, faintly yellow powder, which forms a *hydrochloride*,
$$C_{27}H_{25}N_6, 2HCl,$$
m. p. 218° (*platinichloride*, yellowish-red crystals), in the cold, but is converted into its generators by hot acids. The corresponding *o-nitrobenzylidene*, *salicylidene*, and *anisylidene* compounds, m. p. 89°, 120°, and 219° respectively, are described.   C. S.

5-Amino-1-*o*- and *p*-tolyl-3-methylpyrazoles. August Michaelis and Ludwig Klappert (*Annalen*, 1913, **397**, 149—159) —*Aceto-acetonitrile-o-tolylhydrazone*, $CN \cdot CH_2 \cdot CMe : N \cdot NH \cdot C_7H_7$, m. p. 115°, colourless needles, prepared from acetoacetonitrile and *o*-tolylhydrazine in 30% acetic acid, is converted, by heating with alcoholic hydrochloric acid at 120° for three hours and basifying, into 5-*amino*-1-*o*-*tolyl*-3-*methylpyrazole* (5-*imino*-1-*o*-*tolyl*-3-*methylpyrazolone*),

$$\begin{matrix} CH_2 \cdot C(:NH) \\ CMe:N \end{matrix}\!\!>\!\!N \cdot C_7H_7 \text{ or } \begin{matrix} CH:C(NH_2) \\ CMe:N \end{matrix}\!\!>\!\!N \cdot C_7H_7,$$

m. p. 93°, b. p. 314°, colourless crystals (*hydrochloride*, m. p. 113°), which reacts in hydrochloric acid with chlorine, in glacial acetic acid with bromine, and in alcohol with iodine, to form, after basifying, 4-*chloro*-5-*amino*-1-*o*-*tolyl*-3-*methylpyrazole*, m. p. 114°, and the 4-*bromo*-compound, m. p. 134°, and the 4-*iodo* compound, m. p. 141°, respectively. By prolonged treatment with chlorine, a hydrochloric acid solution of 5-amino-1-*o*-tolyl-3-methylpyrazole yields 4-*chloro*-1-*o*-*tolyl*-3-*methyl*-4 : 5-*azipyrazole*, $N\!\!<\!\!\begin{matrix} CMe\text{---}CCl \\ N(C_7H_7)C \end{matrix}\!\!>\!\!N$, m. p. 107°, red leaflets.   4-*Bromo*-1-*o*-*tolyl*-3-*methyl*-4 : 5-*azipyrazole*, m. p. 115°, red needles, and the 4-*iodo*-compound, m. p. 133°, reddish-brown leaflets, are prepared in a similar manner by means of bromine in acetic acid, and by alcoholic iodine at 140—150°.

5-Amino-1-*o*-tolyl-3-methylpyrazole is converted into 5-*acetylamino*-1-*o*-*tolyl*-3-*methylpyrazole*, m. p. 157°, colourless needles, by boiling acetic anhydride, into 4-*benzeneazo*-5-*amino*-1-*o*-*tolyl*-3-*methylpyrazole*, m. p. 118°, yellow leaflets, by benzenediazonium chloride in hydrochloric acid and subsequent addition of sodium carbonate, into 4-*oximino*-5-*imino*-1-*o*-*tolyl*-3-*methylpyrazolone*, m. p. 195°, red crystals, by sodium nitrite and 30% acetic acid, and into 5-*amino*-1-*o*-*tolyl*-3-*methylpyrazole methiodide*, $CH\!\!<\!\!\begin{matrix} C(NH_2) \cdot N \cdot C_7H_7 \\ CMe\text{---}NMeI \end{matrix}$, m. p. 245°, colourless crystals, by boiling methyl alcoholic methyl iodide. The methiodide is changed by silver chloride to the *methochloride*, m. p. 241°, an aqueous solution of which yields, by treatment with concentrated sodium hydroxide, 2 : 5-*imino*-1-*o*-*tolyl*-2 : 3-*dimethylpyrazole* (1-*o*-*tolyl*-

iminopyrine), $\mathrm{C}\!\!\Big\langle\!\!\begin{array}{c}\mathrm{CH\cdot CMe}\\[-2pt]\mathrm{-NH-}\\[-2pt]\mathrm{N(C_7H_7)}\end{array}\!\!\Big\rangle\!\mathrm{NMe}$, m. p. 35—36°, yellow crystals,

from which have been prepared the *carbonate*, m. p. 98° (decomp.), *picrate*, m. p. 165°, yellow needles, *benzenesulphonyl* derivative,

$$\mathrm{C_{18}H_{19}O_2N_3S},$$

m. p. 179°, *benzoyl* derivative, m. p. 186°, and 4-*benzeneazo*-1-*o*-*tolyl-iminopyrine*, $\mathrm{C_{18}H_{19}N_5}$, m. p. 188°, yellowish-brown leaflets.
The following compounds of the para-series are prepared by methods similar to the preceding: *Acetoacetonitrile*-p-*tolylhydrazone*, m. p. 123°, yellow leaflets; 5-*amino*-1-p-*tolyl*-3-*methylpyrazole*, m. p. 120°, colourless needles; 4-*bromo*-5-*amino*-1-p-*tolyl*-3-*methylpyrazole*, m. p. 128°, colourless needles; 4-*bromo*-1-p-*tolyl*-3-*methyl*-4:5-*azipyrazole*, m. p. 103°, orange-red leaflets; 4-*oximino*-5-*imino*-1-p-*tolyl*-3-*methyl-pyrazolone*, m. p. 198°, bordeaux-red crystals; 5-*amino*-1-p-*tolyl*-3-*methylpyrazole methiodide*, m. p. 135°, and *methochloride*; 1-p-*tolyl-iminopyrine* (*picrate*, m. p. 177°, yellow needles; *benzenesulphonyl* derivative, m. p. 203°; *carbonate*, decomp. 126°; and 4-*benzeneazo*-derivative, m. p. 191°, yellowish-brown leaflets).　　　C. S.

5-p-Carboxylic Acids of Anilopyrine and their Esters. August Michaelis and Wilhelm Titius (*Annalen*, 1913, **397**, 159—180).— The main object of the research is the production of further evidence in support of Michaelis's constitution for the iminopyrines. Antipyrine chloride and methyl p-aminobenzoate (3 mols.), heated at 130°, yield, by basifying the aqueous solution of the product, *methyl* 2:5-*anilo*-1-*phenyl*-2:3-*dimethylpyrazole*-p-*carboxylate* (*methyl anilopyrine*-p-*carboxylate*),

$$\mathrm{C\!\!\begin{array}{c}\mathrm{OMe\colon\!NMe}\\ |\qquad\quad\;\;\mathrm{NPh}\\ \mathrm{CH=\!C}\end{array}\!\!\!\!\Big\rangle N\cdot C_6H_4\cdot CO_2Me},$$ m. p. 155°, greenish-yellow prisms,

which forms a *hydrochloride*, m. p. 142°, *platinichloride*, m. p. 200°, red crystals. *hydriodide*, m. p. 212° (decomp.), colourless needles, and *methiodide*, $\mathrm{C_{20}H_{22}O_2N_3I,3H_2O}$, m. p. 102° (anhydrous, 202° [decomp.]), and is converted into the 4-bromo-compound, $\mathrm{C_{19}H_{18}O_2N_3Br}$, m. p. 170°, yellow leaflets, by bromine in acetic acid. By hydrolysing the ester with concentrated alcoholic potassium hydroxide and treating the product with hydrochloric acid and finally with aqueous potassium iodide, the *hydriodide*, m. p. 236°, colourless needles, of anilopyrine-p-carboxylic acid is obtained. According to the authors, it has the

constitution $\mathrm{CO_2H\cdot C_6H_4\cdot NH\cdot C\!\!\begin{array}{c}\mathrm{NPh\cdot NMeI}\\ \!\!\big\langle\quad\;\;\|\\ \mathrm{CH-CMe}\end{array}}$, and by treating its

aqueous solution with silver oxide yields the *betaine*,

$$\mathrm{C\!\!\begin{array}{c}\mathrm{OMe\colon\!NMe\!-\!-\!O}\\ |\qquad\quad\;\mathrm{NPh}\qquad\;\big\rangle CO,\\ \mathrm{CH=\!C\cdot NH\cdot C_6H}\end{array}}$$

which crystallises in needles containing $5\mathrm{H_2O}$, m. p. 99—100° (the anhydrous substance is yellow and has m. p. about 150°), has a neutral reaction in dilute aqueous or alcoholic solution and a distinctly alkaline reaction in concentrated solution, does not form salts

with bases, but does so readily with acids (*hydrochloride*, $C_{18}H_{17}O_2N_3, HCl$; *platinichloride*, $2C_{18}H_{17}O_2N_3, H_2PtCl_6$, m. p. 217°, golden-yellow crystals), and, although soluble in aqueous alkalis, is precipitated therefrom by carbon dioxide. If iminopyrine has the constitution,

$$NPh<\begin{matrix} C(:NH)\cdot CH \\ | \quad\quad || \\ NMe\!-\!-\!CMe \end{matrix}$$. ascribed to it by Roser and Stolz (A., 1904, i, 113),
the preceding betaine must have the constitution

$$CO_2H\cdot C_6H_4\cdot N\!:\!C<\begin{matrix} NPh\cdot NMe \\ CH\!=\!CMe \end{matrix}'$$

and therefore should exhibit acid properties. The betaine and methyl-alcoholic methyl iodide yield the hydriodide, m. p. 212°, of

methyl anilopyrine-*p*-carboxylate, $CO_2Me\cdot C_6H_4\cdot NH\cdot C<\begin{matrix} NPh\cdot NMeI \\ CH\!-\!CMe \end{matrix}$.

By evaporating a hydrochloric acid solution of methyl anilopyrine-*p*-carboxylate and heating the residue under reduced pressure, methyl chloride is evolved, and the product, after treatment with sodium hydroxide, yields 5-anilo-1-phenyl-3-methylpyrazolone. This substance is produced by the decomposition of the initially-formed *5-anilo-1-phenyl-3-methylpyrazolone-p-carboxylic acid*, $CO_2H\cdot C_6H_4\cdot N\!:\!C<\begin{matrix} NPh\cdot N \\ CH_2\!-\!CMe \end{matrix}'$ colourless needles containing H_2O, m. p. 114° (the anhydrous substance, m p. 140—150° [decomp.], is yellow).

Methyl 5-methylanilino-1-phenyl-3-methylpyrazole-p-carboxylate (*methyl ψ-anilopyrine-p-carboxylate*), $CO_2Me\cdot C_6H_4\cdot NMe\cdot C<\begin{matrix} NPh\cdot N \\ CH\!-\!CMe \end{matrix}'$, m. p. 132°, colourless needles, is obtained by heating the methiodide of methyl anilopyrine-*p*-carboxylate at 200° under reduced pressure. It is converted into the 4-*nitroso*-compound, $C_{19}H_{18}O_3N_4$, m. p. 151°, pale green leaflets, by sodium nitrite and glacial acetic acid containing a few drops of hydrochloric acid, into the 4-*nitro*-compound, $C_{19}H_{18}O_4N_4$, m. p. 170°, pale yellow needles, by nitric acid, into a *dibromo*-derivative, $C_{19}H_{17}O_2N_3Br_2$, m. p. 115°, by bromine on the water-bath, and into the corresponding *acid*, $C_{18}H_{17}O_2N_3$, m. p. 193°, by hydrolysis. This acid is isomeric with the betaine mentioned previously, but exhibits pronounced acid reaction and properties, being soluble in dilute alkali hydroxides and carbonates and in ammonia; the crystalline *barium* salt, $Ba(C_{18}H_{16}O_2N_3)_2$, is described.

Ethyl 2:5-anilo-1-phenyl-2:3-dimethylpyrazole-p-carboxylate (*ethyl anilopyrine-p-carboxylate*), $C_{20}H_{21}O_2N_3$, m. p. 76°, greenish-yellow, fluorescent crystals, is prepared in the same manner as the methyl ester. It forms a *hydriodide*, $CO_2Et\cdot C_6H_4\cdot NH\cdot C<\begin{matrix} NPh\cdot NMeI \\ CH\!-\!CMe \end{matrix}$ yellow crystals containing H_2O, m. p. 110—111°, *methiodide*,

$$CO_2Et\cdot C_6H_4\cdot NMe\cdot C<\begin{matrix} NPh\cdot NMeI \\ CH\!-\!CMe \end{matrix}'$$
colourless crystals containing 3H_2O, m. p. 80° (anhydrous, 183°), and *ethiodide*, $C_{22}H_{26}O_2N_3I$, m. p. 176°, colourless needles, and by hydrolysis yields the same betaine as the methyl ester.

By heating the methiodide of the ethyl ester at 160—180° under re-

duced pressure, *ethyl 5-methylanilino-1-phenyl-3-methylpyrazole-p-carboxyl-ate* (*ethyl ψ-anilopyrine-p-carboxylate*), $CO_2Et \cdot C_6H_4 \cdot NMe \cdot C \underset{CH—CMe'}{\overset{NPh \cdot N}{<}}$
m. p. 105°, colourless needles, is obtained, by the hydrolysis of which ψ-anilopyrine-*p*-carboxylic acid, m. p. 193°, is obtained.

In a similar manner the ethiodide of the ethyl ester yields *ethyl 5-ethylanilino-1-phenyl-3-methylpyrazole-p-carboxylate*, m. p. 95°, colourless needles.   C. S.

Synthesis of Herzynine. R. ENGELAND and FRIEDRICH KUTSCHER (*Chem. Zentr.*, 1913, i, 28—29 ; from *Zentr. Physiol.*, 1912, **26**, 569—570. Compare A., 1911, ii, 528).—The substance, $C_9H_{15}O_2N_3$, which was isolated from mushrooms in the form of the aurichloride, has been identified with trimethylhistidine. This base is prepared by treating histidine hydrochloride in concentrated hydrochloric acid with silver nitrite and warming the syrup obtained by evaporating the filtrate with an alcoholic solution of trimethylamine, when the base is precipitated by phosphotungstic acid, converted into the chloride, then into the platinichloride, and finally into the *aurichloride*,

$$C_9H_{17}O_2N_3Au_2Cl_8,$$

m. p. 183° (decomp.). The direct methylation of histidine affects the glyoxaline ring, and, under certain conditions, a good yield of *penta-methylhistidine* may be obtained as an unstable base which forms a stable chloride and a sparingly soluble *aurichloride*, $C_{11}H_{21}O_2N_3Au_2Cl_8$, m. p. 220°, but does not respond to the diazo-reaction.   J. C. W.

The Identity of Trimethylhistidine (Histidine-betaine) from Various Sources. GEORGE BARGER and ARTHUR J. EWINS (*Biochem. J.*, 1913, **7**, 204—206).—Proof is given of the identity of the histidine-betaine described by the author (T., 1911, **99**, 2336) with the compounds obtained by Reuter and Kutscher. The difference in the m. p. given for the dipicrate is due to this substance melting at 123—124° when hydrated ($2H_2O$) and at 205—206° when anhydrous. The dipicrate has m. p. 213°; the monopicrate, m. p. 201—202°. The aurichloride of betaine has m. p. 184°, not at 171° as previously stated. Histidine-betaine has $[\alpha]_D + 46 \cdot 5°$.   W. D. H.

Synthetical Alkaloids from Tyrosine, Tryptophan and Histidine. JULIUS WELLISCH (*Biochem. Zeitsch.*, 1913, **49**, 173—194).—The author discusses the mechanism of the various processes by means of which physiologically active bases can be synthesised in plants, especially from amino-acids which can be derived from the hydrolysis of proteins. Amongst these may be reckoned in the first instances, bases such as 3-β-aminoethylglyoxaline, 3-β-aminoethylindole, and phenylethylamine, which are derived from histidine, tryptophan, and phenylalanine by the simple scission of carbon dioxide. Another important series derivable from these amino-acids are the quinoline and pyridine derivatives, which can be obtained from the acids or the corresponding amines by condensation with aldehydes, such as formaldehyde, and subsequent ring formation. Attempts have been

made to prepare a series of alkaloids by the latter method. By the condensation of histidine with formaldehyde, which was carried out by heating the base with methylal and hydrochloric acid, *tetrahydro-1 : 3 : 5-benzotriazole-6-carboxylic acid*, $C_7H_9N_3O_2,2HCl$, in the form of its *hydrochloride*, m. p. 278° (corr.), was obtained. The *picrate* decomposes about 215°. The hydrochloride is lævorotatory ($[a]_D^{25} = -84\cdot24°$ by the micropolarisation method). On heating in a vacuum to 290°, carbon dioxide is evolved, and the corresponding *iminazole-isopiperidine [tetrahydro-1 : 3 : 5-benzotriazole] hydrochloride*,

$$C_6H_9ON_3,2HCl,$$

which decomposes at 258°, was obtained, and which separates from alcohol in a microcrystalline form. The carboxylic acid cannot be esterified by alcohol and hydrochloric acid, and only with very great difficulty by the action of ethyl iodide on the silver salt. Attempts were made ty obtain a corresponding product by the action of methylal on tryptophan, but a pure substance was not isolated. *l*-Tyrosine under similar conditions gives 7-hydroxytetrahydro*iso*quinoline-3-carboxylic acid (Pictet and Spengler, A , 1911, i, 750), which has $[a]_D^{25} = -45\cdot62°$ in hydrochloric acid. This on heating in a vacuum appears to be converted into an anhydride. The *ethyl* ester and its *picrate* were also prepared. Attempts to condense histidine with acetaldehyde and pyruvic acid did not lead to the isolation of pure products.

S. B. S.

Derivatives of *iso*Cinchomeronic Acid and 2 : 5-Diaminopyridine. HANS MEYER and FRIEDRICH STAFFEN (*Monatsh.*, 1913, 34, 517—533).—Very few derivatives of *iso*cinchomeronic acid (pyridine-2 : 5-dicarboxylic acid) have been described (compare Weidel and Herzig, A., 1886, 477 ; Meyer, A., 1903, i, 364).

*iso*Cinchomeronic acid was obtained for this investigation by the condensation of aldehyde ammonia with twice its weight of paraldehyde in an autoclave at 220—230°, and oxidation of the resultant 2 : 5-methylethylpyridine with the theoretical amount of potassium permanganate. The m. p. of the acid can be raised from 237° to 254° (decomp.) by conversion into the methyl ester and regeneration ; ammonium salt, m. p. 153°. If the acid is heated with excess of thionyl chloride, it is converted into iso*cinchomeronyl chloride*,

$$C_5NH_3(COCl)_2,$$
needles, m. p. 59°, which reacts with methyl alcohol in the cold, producing *methyl* iso*cinchomeronate*, needles, m. p. 164°, which is also obtainable by heating a mixture of the acid and alcohol with sulphuric acid at 100°. The acid chloride in the cold and the methyl ester at 100° react with ammonia solution, forming iso*cinchomeronamide*, $C_5NH_3(CO\cdot NH_2)_2$, colourless crystals, m. p. 310° (decomp.). When boiled in alcoholic solution with an equal weight of hydrazine hydrate, methyl *iso*cinchomeronate is converted into a crystalline solid, from which chloroform extracts the *methyl* ester of iso*cinchomeronic acid hydrazide*, $C_5NH_3(CO_2Me)\cdot CO\cdot NH\cdot NH_2$, yellow scales, m. p. 173° (decomp.), whilst the undissolved residue consists of iso*cinchomerono-hydrazide*, $C_5NH_3(CO\cdot NH\cdot NH_2)_2$, prismatic needles, m. p. 268—269°

(decomp.), with rapid heating, which is obtained in almost theoretical yield if twice the above proportion of hydrazine hydrate be used in the preparation. The dihydrazide condenses with various aldehydes when heated with them, or when shaken in aqueous solution with them; isocinchomeronodibenzylidenehydrazide, colourless needles, m. p. 290°; isocinchomeronodi-o-chlorobenzylidenehydrazide, colourless leaflets, m. p. 308° (decomp.); isocinchomeronodi-4-hydroxy-3-methoxybenzylidene-hydrazide, a yellow, crystalline substance, m. p. 264—266°, which is turned red on the addition of mineral acids. An aqueous solution of the dihydrazide containing the theoretical quantity of hydrochloric acid reacts with sodium nitrite, giving a precipitate of isocinchomerono-diazoimide, $C_5NH_3(CO \cdot N_3)_2$, colourless prisms, m. p. 114° (decomp. with explosion), together with a small amount of an acid substance, a colourless, crystalline powder, m. p. 307° (decomp.), which from its reaction with ferrous sulphate is a 2-substituted pyridine derivative. The carefully-dried hydrazide when boiled with alcohol first dissolves and then gives a deposit of ethylurethylpyridylazoimide,

$$N_3 \cdot CO \cdot C_5NH_3 \cdot NH \cdot CO_2Et,$$
colourless needles, m. p. 153° (with explosion), which by prolonged treatment with boiling alcohol is further converted into 2 : 5-diethyl-urethylpyridine, $C_5NH_3(NH \cdot CO_2Et)_2$, colourless needles, m. p. 198—199°, the ethoxyl groups of which, unlike those of the corresponding derivative of dipicolinic acid, are easily removed by hydriodic acid. The corresponding methylurethylpyridylazoimide,

$$N_3 \cdot CO \cdot C_5NH_3 \cdot NH \cdot CO_2Me,$$
and 2 : 5-dimethylurethylpyridine form colourless needles (which explode at 80—100° if rapidly heated, and melt at above 270° with decomp. if heated slowly) and colourless needles, m. p. 206—207° (decomp.) respectively.

If the above diethylurethylpyridine is boiled for three hours with hydriodic acid (D 1·8—1·9), yellow needles and leaflets of the hydriodide of 2 : 5-diaminopyridine separate on cooling ; the free base, colourless needles, m. p. 107—110°, which is rapidly affected by air and light, can be isolated by triturating the hydriodide with crushed potassium carbonate and carefully extracting with hot benzene in an atmosphere of carbon dioxide. By the action of silver chloride the hydriodide is converted into the hydrochloride, colourless needles, which, like the free base, gives solutions in water and alcohol with a blue fluorescence ; the unstable platinichloride crystallises in golden-yellow scales ; benzoyl derivative, colourless needles, m. p. 229—230°. The base does not possess the usual properties of an aromatic para-diamine ; it gives an intense reddish-yellow coloration with ferric chloride, and the hydrochloride reduces gold solutions and ammoniacal silver solutions.   D. F. T.

Preparation of Acylacetic Esters. ANDRÉ WAHL and M. DOLL (*Bull. Soc. chim.*, 1913, [iv], **13**, 265—281. Compare A., 1911, i, 108).—The authors have continued their previous work on the condensation of ethyl acetate with its higher homologues by means of sodium, and have improved the yields by suitable modification of the

procedure, which is fully described.   They have also extended the method to the cases of ethyl valerate and ethyl heptoate, and find that the yield of ketonic ester increases with increasing length of the carbon chain of the ester provided the latter is normal.   With esters having side-chains, condensation is effected with greater difficulty.

Ethyl propionylacetate has now been obtained in 13% yield.   It forms a green *copper* salt, m. p. 144°.

Ethyl butyrylacetate is readily converted into *ethyl isonitrosobutyryl-acetate*, which did not solidify even after several months and could not be distilled without decomposition.   Phenylhydrazine converts it into *4-oximino-1-phenyl-3-propyl-5-pyrazolone*, yellow needles, m. p. 128°.   When acted on by benzenediazonium chloride, ethyl butyrylacetate is converted into a yellow *oil*, which is identified as ethyl phenylazo-butyrylacetate, since it is converted by phenylhydrazine into *4-phenyl-hydrazino - 1-phenyl - 3 - propyl- 5 -pyrazolone*, $NPh<\begin{smallmatrix}CO{-}C{:}N{\cdot}NHPh\\ N{=\!=}CPr\end{smallmatrix}$, orange needles, m. p. 133—134°, and by *p*-nitrophenylhydrazine into *4-phenylhydrazino-1-p-nitrophenyl-3-propyl-5-pyrazolone*, golden-yellow needles, m. p. about 209—210°.   *Ethyl p-nitrophenylazobutyrylacetate* crystallises in fine yellow needles, m. p. 101°, whilst the corresponding *acid*, prepared by saponification of the ester with cold alcoholic sodium hydroxide and subsequent addition of acid, forms yellow crystals, m. p. 164°.   *4-p-Nitrophenylhydrazino-1-phenyl-3-propyl-5-pyrazolone*, $NPh<\begin{smallmatrix}CO{-}C{:}N{\cdot}NH{\cdot}C_6H_4NO_2\\ N{=\!=}CPr\end{smallmatrix}$, red needles, m. p. 194°, 4-p-*nitro-phenylhydrazino-1-p-nitrophenyl-3-propyl-5-pyrazolone*, orange needles, m. p. 243—244°, and *4-p-nitrophenylhydrazino-1-tolyl-3-propyl-5-pyra-zolone*, orange needles, m. p. 152°, were also prepared.

Ethyl valerylacetate, $CH_2Pr{\cdot}CO{\cdot}CH_2{\cdot}CO_2Et$, b. p. 110—112°/16 mm. (compare Blaise and Luttringer, *Bull. Soc. chim*, 1905, [iii], **33**, 1103), is obtained in 28% yield.   It gives a *copper* salt, green needles, m. p. 91°, which, when boiled with methyl alcohol, is converted into a blue basic *salt*, $C_9H_{15}O_3{\cdot}CuOMe$, m p. 80°.   It is transformed by hydrazine hydrate into *3-n-butylpyrazolone*, white leaflets, m. p. 197°.

Ethyl *iso*valerate reacts slowly with ethyl acetate with the formation of poor yields of *ethyl isovalerylacetate*, b. p. 96—99°/14 mm.   The latter gives a green normal *copper* salt, m. p. 122°, which when boiled with methyl alcohol forms indigo-blue crystals of the basic *salt*,

$$C_9H_5O_3{\cdot}CuOMe,$$
m. p. 106—107°.

Ethyl heptoylacetate, b. p. 123—126°/11 mm. (compare Moureu and Delange, A., 1903, i, 676), is obtained in 40% yield by the condensation of ethyl heptoate with ethyl acetate.   The following new compounds have been prepared from it : *4-phenylhydrazino-1-phenyl-3-hexyl-5-pyrazolone*, orange-yellow needles, m. p. 100—101° ; *4-p-nitrophenyl-hydrazino-1-p-nitrophenyl-3-hexyl-5-pyrazolone*, orange needles, m. p. 192° ; *1-phenyl-3-hexyl-5-pyrazolone*, nearly white leaflets, m. p. 83—84°, formed by heating at its b. p. for a few moments an acetic acid solution of molecular quantities of the ketonic ester and phenylhydrazine.   If

CH$_3$·[CH$_2$]$_5$·C—CH—CH—C·[CH$_2$]$_5$·CH$_3$

N CO   CO N

CH$_3$·[CH$_2$]$_5$·C—C≡C—C·[CH$_2$]$_5$·CH$_3$

N CO CO N

NPh   NPh

(II.)
in the latter case 2 to 3 molecules of phenylhydrazine are employed for each molecule of ketonic ester, 1-*phenyl*-3-*hexylbispyrazolone* (formula I), crystalline powder, m. p. 276—278° (decomp.), is obtained, which, when heated in alkaline solution with sodium nitrite and subsequently acidified, yields the compound (formula II) crystallising in blue needles, m. p. 145°.

The method has also been successfully applied to certain cyclic esters. Ethyl benzoate and ethyl acetate gave ethyl benzoylacetate in 80% yield (compare Wahl, A., 1908, i, 647; Wahl and Silberzweig, A., 1912, i, 114), whilst the corresponding methyl ester gave an 85% yield of methyl benzoylacetate. *Propyl benzoylacetate*, prepared by boiling methyl benzoylacetate with propyl alcohol in a fractionating apparatus so arranged that the displaced methyl alcohol slowly distils, forms an amber liquid, b. p. 154—156°/12 mm., D⁰ 1·114. The normal *copper* salt forms green leaflets, m. p. 145—146°, whilst the basic *salt*, $C_{12}H_{13}O_3$·CuOMe, consists of blue crystals, m. p. 195°.

The normal green *copper* salt, m. p. 133°, of *iso*butyl benzoylacetate is decomposed by boiling methyl alcohol with formation of the bluish-grey basic *salt*, $C_{13}H_{15}O_3$·CuOMe, m. p. 191°, and by boiling ethyl alcohol into the blue basic *salt*, $C_{13}H_{15}O_3$·CuOEt, m. p. 188°.

Under the conditions used in the preparation of the benzoylacetates, a 60% yield of methyl o-methoxybenzoylacetate and a 62% yield of methyl anisoylacetate were obtained. The yield of ethyl furoylacetate was 76% of the theoretical (compare Torrey and Zanetti, A., 1907, i, 146; 1908, i, 840; 1910, i, 892).   H. W.

[Preparation of an Anthracene Derivative.] CHEMISCHE FABRIK GRIESHEIM - ELEKTRON (D.R.-P. 255641).—The *compound* (annexed formula) is obtained when pyrazoleanthrone (A., 1906, i, 904) is boiled with potassium hydroxide (5 parts) and alcohol (10 parts) until the so-obtained blue colour ceases to gain intensity.
F. M. G. M.

New Derivatives of Azoxybenzene. ANGELO ANGELI and BRUNO VALORI (*Atti R. Accad. Lincei*, 1913, [v], 22, i, 132—140. Compare A., 1912, i, 321).—*p*-Azobenzenecarboxylic acid (which has m. p. 241°)

is conveniently prepared from p-aminobenzoic acid and nitrosobenzene When it is treated in acetic acid solution with hydrogen peroxide, β-*azoxybenzenecarboxylic acid*, $NPh{:}NO{\cdot}C_6H_4{\cdot}CO_2H$, is obtained; it crystallises in yellow needles, m. p. 241°. Its *ethyl* ester, $C_{15}H_{14}O_3N_2$, has m. p. 68°. The acid yields p-azobenzenecarboxylic acid on reduction. When it is treated with bromine in the presence of iron filings, p-*bromo*-β-*azoxybenzenecarboxylic acid*, $C_{13}H_9O_3N_2Br$, is produced; it is a yellowish-white, crystalline powder, m. p. 280°. The *ethyl* ester of this acid, $C_{15}H_{13}O_3N_2Br$, has m. p. 114°. When β-azoxybenzenecarboxylic acid is nitrated in glacial acetic acid solution, p-*nitro*-β-*azoxybenzenecarboxylic acid*, $C_{13}H_9O_5N_3$, is obtained as a yellow, crystalline powder, m. p. about 260° with evolution of gas. If kept for an hour on the water-bath with excess of concentrated sulphuric acid, β-azoxybenzenecarboxylic acid undergoes rearrangement, yielding 4-*hydroxyazobenzene*-4'-*carboxylic acid*, $HO{\cdot}C_6H_4{\cdot}N{:}N{\cdot}C_6H_4{\cdot}CO_2H$, which forms red crystals, m. p. 266° (decomp.).

a-*Azoxybenzenecarboxylic acid*, $O{:}NPh{:}N{\cdot}C_6H_4{\cdot}CO_2H$, is formed in the preparation of the β-acid, and can be separated from it by reason of its greater solubility in acetic acid. It is also obtained by the action of chromic acid on the β-compound It forms pale yellow scales, m. p. 231°. Its *ethyl* ester, $C_{15}H_{14}O_3N_2$, has m. p. 77·5°. The a-acid is not acted on by bromine. On reduction with aluminium amalgam, it yields p-azobenzenecarboxylic acid.

β-p-*Azoxybenzenesulphonic acid*, $C_{12}H_{10}O_4N_2S$, prepared by the action of hydrogen peroxide on p-azobenzenesulphonic acid, forms pale yellow needles, m. p. 144°. The *silver* salt, $C_{12}H_9O_4N_2SAg$, crystallises in lustrous laminæ. The acid described under the name of p-azoxybenzenesulphonic acid by Limpricht (A., 1885, 984) cannot have this structure. β-p-Azoxybenzenesulphonic acid yields a bromo-derivative, p-*bromo*-β-*azoxybenzenesulphonic acid*, $C_{12}H_9O_4N_2SBr$, which does not melt at 280°. β-p-Azoxybenzenesulphonic acid suffers the Wallach rearrangement, yielding a red, crystalline powder, $C_{12}H_{10}O_4N_2S$, which blackens about 200°, but does not melt.

a-2 : 4 : 6:*Trinitroazoxybenzene*, $O{:}NPh{:}N{\cdot}C_6H_2(NO_2)_3$, is obtained in long, pale yellow needles, m. p. 170°, by the action of hydrogen peroxide on trinitroazobenzene. This substance dissolves unaltered in nitric acid (D 1·45) and in bromine, but when it is dissolved in nitric acid of D 1·52, and the solution kept for twelve hours, it yields a *tetranitro*-derivative, $C_{12}H_9O_9N_6$, which forms yellow prisms, m. p. 192°.   R. V. S.

Diazo-compounds derived by the Action of Alkali on Nitrosophthalimidine. Simplified Preparation of Nitrosophthalimidine. ALFRED OPPE (*Ber.*, 1913, **46**, 1095—1099).— Aqueous alkali transforms nitrosophthalimidine into o-hydroxymethylbenzoic acid or its lactone (Graebe, A., 1889, 140), diazo-compounds being probably formed as intermediate products. The isolation of the latter has been accomplished by substituting absolute methyl-alcoholic sodium methoxide for aqueous alkali hydroxide in opening the lactam ring.

When a solution of sodium methoxide in absolute methyl alcohol

is added to a well-cooled suspension of nitrosophthalimidine in dry ether, a micro-crystalline salt separates, analysis of which gives results intermediate between those required for the *salt diazoxide*,

$$CO_2Na \cdot C_6H_4 \cdot CH_2 \cdot N_2 \cdot ONa,$$
and the *ester diazoxide*, $CO_2Me \cdot C_6H_4 \cdot CH_2 \cdot N_2 \cdot ONa$. The former could be obtained in the pure state by pouring the freshly-prepared reaction mixture into a large quantity of cooled ether, but the latter could not be obtained pure. When the above reaction mixture is treated with dry carbon dioxide before the separation of crystals occurs, *methyl o-diazomethylbenzoate*, $CO_2Me \cdot C_6H_4 \cdot CH \colon N_2$, needles, m. p. 34°, is obtained, which is readily decomposed by phenol with quantitative evolution of nitrogen and formation of *methyl o-phenoxymethylbenzoate*, $CO_2Me \cdot C_6H_4 \cdot CH_2 \cdot OPh$, needles, m. p. 52·5°, b. p. 204°/13 mm. The corresponding free *acid* crystallises in needles, m. p. 126°, and is decomposed by fuming hydrochloric acid at 170—180° into phenol and *o*-hydroxymethylbenzoic acid. The latter is converted by heat into phthalide, leaflets, m. p. 73°.

The following process is recommended for the preparation of nitrosophthalimidine. Nearly boiling 25% hydrochloric acid is gradually added to a paste made by grinding phthalimide and zinc dust with a small quantity of water. The mixture is maintained at its boiling point until there is no further action on the zinc, filtered, cooled, and treated with a concentrated aqueous solution of sodium nitrite. In this manner, 100 grams of phthalimide yield 75 grams of nitrosophthalimidine.   H. W.

Etherification of *o*-Hydroxyazo-compounds. II. G. CHARRIER and G. FERRERI (*Atti R. Accad. Sci. Torino*, 1913–13, 48, 539—556. Compare A., 1912, i, 812).—1-*Benzeneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \colon NPh$, forms garnet-red tablets, m. p. 79°; in its preparation 50% potassium hydroxide is used instead of 30% sodium hydroxide. When the substance is reduced with zinc and acetic acid, aniline and 1-amino-2-naphthyl ethyl ether are produced. The *hydrochloride*, $C_{18}H_{16}ON_2, 2HCl$, crystallises in heavy, green leaflets, which have a metallic lustre. The *hydrobromide* is a coffee-coloured, crystalline powder. The hydriodide is a heavy, dark coffee-coloured, crystalline powder.

1-*o*-*Tolueneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \colon N \cdot C_6H_4Me$, crystallises in garnet-red, flattened needles, m. p. 36°. It dissolves in concentrated sulphuric acid, giving a red coloration, and dissolves also in dilute acids, forming red solutions. The *hydrochloride*,

$$C_{19}H_{18}ON_2, 2HCl,$$
crystallises in needles with a green, metallic lustre.

1-*m*-*Tolueneazo-2-naphthyl methyl ether*, $OMe \cdot C_{10}H_6 \cdot N \colon N \cdot C_6H_4Me$, forms garnet-red, tabular crystals, m. p. 81°. The *hydrochloride* forms minute, red crystals with a golden lustre.

1-*m*-*Tolueneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \colon N \cdot C_6H_4Me$, crystallises in red leaflets, m. p. 84°. The *hydrochloride* is a heavy, coffee-coloured substance.

1-*p*-*Tolueneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \colon N \cdot C_6H_4Me$, crys-

tallises in red, prismatic needles, m. p. 48°. The *hydrochloride*, $C_{10}H_{18}ON_2,2HCl$, forms reddish-brown needles with a golden lustre.
1-m-*Chlorobenzeneazo-2-naphthyl methyl ether*,
$$OMe \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4Cl,$$
crystallises in bright red prisms or needles, m. p. 77°. The *hydrochloride* forms red needles.

1-m-*Chlorobenzeneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4Cl$, forms red needles, m. p. 35°. The *hydrochloride* forms dark garnet-red crystals with a golden lustre.

1-p-*Chlorobenzeneazo-2-naphthyl methyl ether*,
$$OMe \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4Cl,$$
crystallises in shining red needles, m. p. 65°. The *hydrochloride*, $C_{17}H_{13}ON_2Cl,2HCl$, is a red, crystalline substance.

1-p-*Chlorobenzeneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4Cl$, crystallises in red needles with a golden lustre, m. p. 53°. The *hydrochloride* is a reddish-brown, crystalline powder.
1-op-*Dichlorobenzeneazo-2-naphthyl methyl ether*,
$$OMe \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_3Cl_2,$$
forms garnet-red leaflets, m. p. 98°. The *hydrochloride* is a red, crystalline powder having a metallic lustre.
1-op-*Dichlorobenzeneazo-2-naphthyl ethyl ether*,
$$OEt \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_3Cl_2,$$
separates in garnet-red needles, m. p. 102°. The *hydrochloride* forms minute, reddish-brown crystals with a metallic lustre.
1-m-*Bromobenzeneazo-2-naphthyl methyl ether*,
$$OMe \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4 \cdot Br,$$
crystallises in ruby-red needles, m. p. 92°. The *hydrochloride* is a red, crystalline substance having a metallic lustre.

1-m-*Bromobenzeneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_2 \cdot Br$, forms crusts of golden-yellow needles, m. p. 52°. The *hydrochloride* crystallises in metallic-looking, green leaflets.

The m. p. of 1-p-methoxybenzeneazo-2-naphthylethylether is 55—56°, not 52—53°, as stated in the former paper. The *hydrochloride* of the ether is a reddish-brown, crystalline powder having a green metallic lustre.
1-m-*Nitrobenzeneazo-2-naphthyl methyl ether*,
$$OMe \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4 \cdot NO_2,$$
crystallises in small, red needles, m. p. 94—95°. The *hydrochloride* is a red, crystalline substance, as also is the *hydrobromide*.

1-m-*Nitrobenzeneazo-2-naphthyl ethyl ether*, $OEt \cdot C_{10}H_6 \cdot N \vdots N \cdot C_6H_4 \cdot NO_2$, forms garnet red needles, m. p. 106—107°. The *hydrochloride* is a red, crystalline powder.

The salts of these ethers are to be assigned the constitutions indicated by the following formula:
$$\begin{array}{c} R \\ Cl \end{array} \!\!\! \diagdown \!\!\! \begin{array}{c} \\ \diagup \end{array} O \cdot C_{10}H_6 \cdot N \vdots N \!\!\! \diagup\!\!\!\diagdown \!\!\! \begin{array}{c} Ar \\ Cl \\ H \end{array}.$$

R. V. S.

Hydroxyazo-compounds and Quinonephenylhydrazones of the Anthracene Series.

KURT H. MEYER and KARL ZAHN (*Annalen*, 1913, **396**, 152—166).—Benzeneazoanthranol, identical with the substance obtained by Kaufler and Suchanek by the con-

densation of benzenediazonium chloride and anthranol, is prepared by treating 9 : 9-dibromoanthrone with alcoholic phenylhydrazine; only the one substance is produced at − 10° or at the b. p., or by working in other solvents. The same substance also is immediately recovered when the deep blue solution of benzeneazoanthranol in alcoholic potassium hydroxide is added to sulphuric acid at 0°. No evidence of the existence of the parent substance as anthraquinonephenylhydrazone has been obtained. Benzeneazoanthranol yields differently coloured solutions in different solvents, develops a deep brown coloration with concentrated sulphuric acid, forms coloured additive compounds with stannic chloride and aluminium chloride, reacts instantly with alcoholic bromine, and is stable to boiling acetic acid ; it is hydrolysed by 5% alcoholic sulphuric or hydrochloric acid after boiling for seven hours. All these properties, except variability of colour in solution, are also characteristic of *benzeneazoanthranyl benzoate*,

$$\text{NPh:N·C}\!\!<^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}\!\!>\!\!\text{C·OBz,}$$
m. p. 230—231°, dark red crystals with a metallic lustre, which is prepared by treating benzeneazoanthranol in acetone with aqueous sodium hydroxide and benzoyl chloride in the cold; by prolonged boiling with alcoholic hydrochloric acid, it yields benzoic acid, anthraquinone, and phenylhydrazine. On the contrary, *anthraquinonebenzoylphenylhydrazone*, $\text{NPhBz·N:C}\!\!<^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}\!\!>\!\!\text{CO}$, m. p. 172—173°, orange-yellow prisms, prepared by heating 9 : 9-dibromoanthrone, alcoholic benzoylphenylhydrazine and sodium carbonate, develops a yellow coloration with concentrated sulphuric acid, does not form additive compounds with metallic chlorides, is only slowly attacked by alcoholic bromine, and is rapidly hydrolysed by boiling dilute acetic acid. It cannot be transformed into benzeneazoanthranyl benzoate by ether and powdered potassium hydroxide.

Anthraquinonephenylmethylhydrazone, $\text{NPhMe·N:C}\!\!<^{\text{C}_6\text{H}_4}_{\text{C}_6\text{H}_4}\!\!>\!\!\text{CO}$,

m. p. 147—148°, red prisms with metallic lustre, is obtained by heating 9 : 9-dibromoanthrone with alcoholic *as*-phenylmethylhydrazine or by treating benzeneazoanthranol in aqueous acetone with sodium hydroxide and methyl sulphate. It is not affected by alcoholic potassium hydroxide, but is hydrolysed to anthraquinone and *as*-phenylmethylhydrazine by boiling dilute acetic acid or alcoholic hydrochloric acid. It is thus seen that the acylation of benzeneazoanthranol in alkaline solution is a process of direct substitution (an *O*-ester being formed), whilst the alkylation is a case of addition followed by elimination (an *N*-ether being formed).

At the present time aliphatic hydroxyazo-compounds, such as phenylazoacetylacetone, are generally regarded as hydrazones, for example, NHPh·N:C(COMe)_2, because they yield *N*-esters [NBzPh·N:C(COMe)_2] by acylation. The evidence is by no means conclusive, however, because the hydroxyazo-compound can yield the *N*-ester as follows :

$$\text{ONa·CMe:C(N:NPh)·COMe} \longrightarrow \overset{\text{NaO}}{\underset{\text{Cl}}{}}\!\!>\!\!\text{CMe·C(:N·NBzPh)·COMe}$$

$\longrightarrow$ NBzPh·N:C(COMe)$_2$. The colour, solubility in aqueous alkalis,
and reactivity with alcoholic bromine are all in harmony with the formulation of aliphatic hydroxyazo-compounds as hydroxyazo-compounds.

Anthraquinoneoxime is obtained by treating 9 : 9-dibromoanthrone with alcoholic hydroxylamine and dry sodium carbonate. The same substance is at once precipitated when its alkaline solution is acidified with sulphuric acid at 0°; nitrosoanthranol is not isolated.   C. S.

Action of Acids on Proteins. D. CALUGĂREANU (*Bull. Acad. Sci. Roumaine*, 1912/13, **1**, 40—42).—With the object of deciding whether the products of the action of acids on proteins are chemical compounds which are hydrolytically dissociated in aqueous solution, or are simply adsorption products, the author has studied the electrical conductivity of a number of acids (hydrochloric, sulphuric, chromic, acetic, citric, lactic, trichloroacetic, and picric) at different dilutions in aqueous solution, on the one hand, and in aqueous solution in the presence of various proteins (serum-albumen, serum-globulin, and gelatin) on the other, the experimental conditions being so chosen that the concentration of the protein remains constant, the concentration of acid alone varying.

Since the curves obtained are closely similar to that given by a solution of glycine under similar conditions, the author is led to the conclusion that the form of the curve is largely due to the hydrolytic dissociation of the product of the action of acids on the protein. He does not consider, however, that the phenomenon of adsorption is completely excluded.   H. W.

The Relations of the Phenols and their Derivatives to Proteins. Mechanism of Disinfection. II. Effects of Various Factors on the Germicidal and Protein-precipitating Powers of the Phenols. EVELYN A. COOPER (*Biochem. J.*, 1913, **7**, 175—185. Compare A., 1912, ii, 1199).—The introduction of hydroxyl groups decreases, and of nitro- or methyl groups, increases, the bactericidal and protein-precipitating powers of phenol. The monohydric phenols are superior to the alcohols in both directions. Sodium chloride increases both properties through increasing the solubility of phenols in proteins; alcohol behaves in the opposite way. Solutions of phenol in fat possess no such activities. Small amounts of alkali inhibit the power to precipitate proteins, without affecting the germicidal power; the explanation of this is not apparent. The precipitating action of phenol is increased by the addition of acids. The absorption of phenols by bacteria is the initial stage in disinfection; the germicidal action is not due to a union of the phenols with the bacterial protoplasm (as with formaldehyde), but to a de-emulsifying action upon the colloidal suspension of some constituent protein or proteins essential for the vitality of the organisms.

W. D. H.

The Relations of the Phenols and their Derivatives to Proteins. Mechanism of Disinfection. III. The Chemical Action of *p*-Benzoquinone on Proteins. EVELYN A. COOPER (*Biochem. J.*, 1913, **7**, 186—196).—*p*-Benzoquinone gives a red colour

with various proteins and amino-acids (confirmatory of Würster and Raciborski); the proteins can be isolated in a coloured state from the solutions, but could not be decolorised. Their solubilities and other properties are changed, hence they had been chemically altered. *p*-Benzoquinone in absolute alcohol does not produce the colour; and treatment of the proteins with formaldehyde inhibits the reaction, except in the case of gelatin, aniline, and ammonia. The effect of formaldehyde indicates that proteins, proteoses, and amino-acids react with *p*-benzoquinone through their amino- or imino-groups. No colour reaction was obtained with *p*-benzoquinonedioxime, which shows probably that the reacting groups of the proteins condense with the ketonic groups of the quinone. The effect of the latter therefore resembles that of formaldehyde. Acetone differs from *p*-benzoquinone by acting as a protein precipitant. The germicidal power of *p*-benzoquinone is due to its chemical action on some constituent protein or proteins of the bacteria. W. D. H.

Nitro-derivatives of the Proteins. ALBRECHT KOSSEL and FRANZ WEISS (*Zeitsch. physiol. Chem.*, 1913, **84**, 1—10).—The arginine group in the molecule of the higher proteins is as accessible to nitration by means of a mixture of concentrated nitric and sulphuric acids as that in the protamines.

Nitroclupeine, like nitroarginine, when digested at 38° with normal sodium hydroxide solution loses carbon dioxide, ammonia, and nitrous oxide, a derivative of ornithine being formed. The amount of gas formed confirms this interpretation of the change, and the method is applicable to the determination of the nitro-group in nitroguanidine and of the nitroamino-groups in nitrated proteins.

In the case of edestin it is shown that in addition to the guanidine complex of the arginine constituent a further guanidine complex is present in the molecule, which forms a nitroamine. This is in agreement with Otori's (A., 1904, i, 1067) suggestion of such a second guanidine complex in ψ-mucin, casein, and gelatin. E. F. A.

Action of Arsenious Acid, Arsenic Acid, and Phosphoric Acid on Albumin. CORRADO BONGIOVANNI (*Gazzetta*, 1913, **43**, i, 161—163).—From measurements of the conductivity of solutions of albumin and of the above acids separately, and of the binary mixtures of the acids with albumin, the author finds no evidence that combination with the albumin occurs. The diminution of conductivity which takes place on mixing is to be ascribed to a lessening of the mobility of the ions by the colloidal substance. R. V. S.

Acid Decomposition Products of Hæmin. OSKAR PILOTY and EDMUND DORMANN (*Ber.*, 1913, **46**, 1002—1008).—The acid decomposition products of hæmin obtained on reduction with hydrogen iodide and acetic acid contain four components: phonopyrrolecarboxylic acid, xanthopyrrolecarboxylic acid, *iso*phonopyrrolecarboxylic acid, and an acid so far only obtained as a syrup.

In view of the possibility that xanthopyrrolecarboxylic acid, $C_{10}H_{15}O_2N$, might be *iso*phonopyrrolecarboxylic acid, $C_9H_{13}O_2N$,

contaminated with the product of the action of ethyl alcohol on its picrate, it has been further investigated and its individuality established.

The picrate of phonopyrrolecarboxylic acid when heated in ethyl or methyl alcoholic solution in presence of free picric acid is rapidly and completely esterified at the carboxyl group. The free methyl ester crystallises in long, flat, colourless needles, m. p. 59°; its picrate has m p. 122°. The corresponding *ethyl* ester forms six-sided, colourless plates, m. p. 134°; its *picrate* crystallises in pale yellow, flat, prismatic needles of rhombic habit, m. p. 93°.

The acid mixture yields a fourth crystalline acid, $C_{10}H_{15}O_2N$, *phonopyrrolecarboxylic acid*-d, which crystallises in colourless needles pointed at either end. The *picrate* separates in characteristic yellow crystals, m. p. 132°. The new acid is perhaps identical with compounds described by H. Fischer (A., 1912, i, 384, 901), and obtained by the action of sodium methoxide on pyrrole derivatives.   E. F. A.

Sulphuric Acid Hæmatoporphyrin. ANT. HAMSIK (*Zeitsch. physiol. Chem.*, 1913, 84, 60—66).—Hæmatoporphyrin, prepared from hæmin by means of concentrated sulphuric acid, was obtained as an amorphous, dark blue powder. By solution in acetic acid containing 10% of water, the addition of concentrated hydrochloric acid, and enough dilute acid to make the amount of water 40%, the pigment was obtained partly crystalline in dark green needles or long rods, usually aggregated in stellate or bunched clusters, and partly crystalline in red aggregates of varying size, or in indefinite green masses.

Crystals were also obtained by dissolving the original product in acetone and hydrochloric acid.   E. F. A.

The Kinetics of Invertin Action. LEONOR MICHAELIS and (Miss) MAUD L. MENTEN (*Biochem. Zeitsch.*, 1913, 49, 333—369).—The authors, whilst accepting generally Victor Henri's generalisations as to the method of the ferment action, call attention to two defects in his experimental method. They show that the hydrogen-ion concentration of the solutions has not been taken into account, and that the multirotation of sugar has been neglected. They remedy the first defect by working in an acetate mixture, prepared according to Sörensen, which gives the optimal conditions of action, and they remedy the second defect by reading the polarisations after the sugar mixture has been allowed to remain with sodium hydroxide solution, which inhibits the action of the ferment. Like Henri, therefore, they use the polarimetric method for investigating the change. They assume that the invertin enters into combination with sucrose to form a labile compound, which decomposes according to the scheme : 1 mol. sucrose–invertin compound $\longrightarrow$ 1 mol. dextrose + 1 mol. lævulose + 1 mol. invertin. It is only through the intermediation of the sucrose–invertin compound that inversion takes place. The invertin can also combine with the scission products to form compounds, but as these are not labile, the only effect of their formation is to diminish the amount of ferment available for combination with the sucrose, and thus to inhibit the inversion. The present communication deals chiefly with the

methods for the determination of the dissociation constants of the various invertin–sugar compounds. For sucrose, the following equation is evolved : $v = C\Phi.[S]/([S]+k)$, where v is the initial reaction velocity, C is a constant depending on the arbitrarily chosen units employed for measuring change (in this case the rotation changes), S is the concentration of the sugar. k the dissociation constant, and Φ the concentration of the ferment. If Φ is kept constant and S is altered, $v/C\Phi$ can be replaced by V, and the equation becomes $V=[S]/([S]+k)$, which is identical in form with the residuary dissociation curve of an acid. The methods are given (graphic and others) for determining k, which for the sucrose–invertin compound was found to be 0·0167. By measuring the inhibition of inversion produced by various carbohydrates, the dissociation constant of the compounds of invertin with other sugars was ascertained. For this purpose the equation : $k^1 = Fk/\{(S+k)(v_0/v_1 - 1)\}$, was evolved. where k^1 is the constant in question, F is the amount of inhibitory sugar, v_0 and v_1 the initial rates of inversion in the presence and absence of inhibitory sugars (such as lævulose), and the other symbols have the meanings already described. It was found that mannitol and glycerol, as well as carbohydrates, had a power of combining with invertin, but that the affinity for these of the ferment, as determined by the dissociation constants, was less than that for sucrose. Lactose had practically no combining power, and therefore does not appreciably inhibit sugar inversion. The decomposition of the sucrose–invertin compound was found to be a unimolecular reaction. S. B. S.

The Dialysis of Maltase. LADISLAS KOPACZEWSKI (*Compt. rend.*, 1913, **156**, 918—921).—A sample of maltase (taka-diastase) was submitted, first to ordinary dialysis, and then to Dhéré's process of electrical dialysis (compare A., 1910, ii, 515). Ordinary dialysis causes the hydrolysing power of the maltase to increase very considerably to a maximum (200% of original power), after which it diminishes slightly to 180%. Prolonged dialysis produces no further change. Electrical dialysis at this stage removes more of the electrolytes present, and produces a slight further diminution in the diastatic power. The maltase travels in the electrical field towards the negative pole ; thus purified, the maltase has a feebly acid reaction to helianthin, and conductivity measurements give $K = 3\cdot8 \times 10^{-6}$.
W. G.

Action of Ammonia Gas on Diastase. III. THEODOR PANZER (*Zeitsch. physiol. Chem.*, 1913, **84**, 161—188. Compare A., 1912, i, 113).—When dry ammonia gas is passed over diastase preparations a small quantity is absorbed. In addition to ammonium salt formation and physical adsorption, ammonia is taken up and an equivalent of water liberated in two ways. In one instance an atomic group is formed, which combines both with acids and with formaldehyde ; in another, the new group has neither of these properties. Such changes are assumed to indicate the replacement of an alcoholic hydroxyl by an amino-group and the interaction of an aldehyde group with ammonia.

The enzymic activity of the diastase is increased rather than hindered by the action of the ammonia. It is assumed that diastatic activity is not connected with the presence of a free aldehyde group or of an alcoholic hydroxyl.   E. F. A.

The **Reversibility of Ferment Actions**: Emulsin and β Methyl Glucoside. EMILE BOURQUELOT and ÉMILE VERDON (*Compt. rend.*, 1913, **156**, 957—959).—Experiments on β-methyl glucoside and emulsin confirm in every respect the results previously obtained with β-ethyl glucoside (compare Bourquelot and Bridel, A., 1912, i, 928 ; this vol., i, 212 ; Bourquelot and Coirre, this vol., i, 410).   W. G.

Action of High Temperatures on the Dried Nucleases of Vegetable Origin. E. C. TEODORESCO (*Compt. rend*, 1913, **156**, 1081—1084. Compare A., 1912, i, 1042).—A study of the effect of heat on the enzymatic properties of dried nucleases from four different sources of vegetable origin. The dried nucleases of the plants studied only lose their activity towards sodium nucleate after heating for thirty minutes at the following moderately high temperatures. The nuclease from *Evernia prunastri* becomes inactive at 145°, that from *Lycoperdon gemmatum* between 141° and 156°, that from brewer's yeast at 153°, and that from *Sticta pulmonacea* at 162°.   W. G.

Preparation of a Nitro-3-aminophenyl-1-arsinic Acid. FARBWERKE VORM. MEISTER, LUCIUS & BRUNING (D.R.-P. 256343).— Two isomeric nitroaminophenylarsinic acids are known, and the third isomeride has now been prepared as follows :

Carboethoxy-m-arsanilic acid, m. p. 180° (decomp.), is obtained by treating an aqueous solution of 3-aminophenylarsinic acid with ethyl chloro-formate ; this, when dissolved in fuming sulphuric acid at 0° and treated with nitric acid (26%), furnishes the corresponding *nitro*-compound (a yellow, crystalline powder), which, on hydrolysis at 70—80° with concentrated sulphuric acid, gives rise to 2-*nitro-3 amino-phenylarsinic acid*, orange-yellow needles.

2 : 3-*Diaminophenylarsinic acid*, obtained by reducing the preceding compound with sodium hyposulphite at the ordinary temperature, forms glistening leaflets, m. p. 205—208° ; it furnishes an *azoimide* on treatment with nitrous acid.

2-*Nitro-3-hydroxyphenylarsinic acid* is obtained by the action of concentrated potassium hydroxide on 2-nitro-3-aminophenylarsinic acid, and this on reduction with sodium hyposulphite gives rise to 2 : 2'-*diamino-3 : 3'-dihydroxyarsenobenzene*.   F. M. G. M.

Physiological Chemistry.

Oxidising and Reducing Enzymes and their Rôle in the Process of Respiration. ALEXIS BACH (*Arch. Sci. phys. nat*, 1913, **35**, 240—262).—A summary of the present knowledge of the subject. Emphasis is laid on the following conclusions. (1) In order to utilise the oxygen of the air to effect oxidation, the cell produces an enzyme (an oxygenase), a substance which is readily oxidised, fixing molecular oxygen to form a peroxide. (2) A second enzyme (the peroxydase) accelerates the oxidising action of the peroxides, acting on them in the same way as ferrous sulphate does towards hydrogen peroxide. (3) The peroxides are readily transformed by hydrolysis into hydrogen peroxide, which is also formed as a primary product during hydrolytic oxidation. Owing to its rapid rate of diffusion, this accumulation of hydrogen peroxide might damage the cell protoplasm. To guard against this, the cell produces an enzyme-catalase, which rapidly decomposes hydrogen peroxide into water and inert oxygen. Catalase thus acts as a regulator of the respiratory process. (4) To effect hydrolytic oxidation, an enzyme, perhydridase, is present, which accelerates both oxidation and reduction just as do the metals of the platinum group. The reductase consists of the enzyme, water, and an oxidisable substance which fixes the oxygen derived from the water, leaving the hydrogen free to effect reduction. E. F. A.

Mechanism of Stimulation by Lack of Oxygen. H. S. GASSER and ARTHUR S. LOEVENHART (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xxx—xxxi; *J. Biol. Chem.*, **14**).—Lack of oxygen decreases the oxidation, and so stimulates the cells of the respiratory, cardio-inhibitory, and vaso-motor centres. Decrease in oxidation stimulates per se, and not by the accumulation of katabolic products. W. D. H.

The Relationship between the Sugar Content of Erythrocytes and Glycolysis. ADAM LOEB (*Biochem. Zeitsch.*, 1913, **49**, 413—425).—Observations of previous observers are confirmed, according to which the red blood corpuscles of different species possess different contents of sugar, which are characteristic of each species. In the case of man, the corpuscles contain about the same percentage of sugar as the serum; in the dog they contain less, and in the case of sheep and pig, the corpuscles only contain very small amounts of sugar. The corpuscles of ox occupy an intermediary place as regards the sugar content. The larger the sugar content of corpuscles, the greater the amount of glycolysis they produce on incubation. The conclusion is drawn that those corpuscles produce glycolysis most readily which are the most readily permeable by sugar. Glycolysis of added sugar is therefore not wholly dependent on the presence of white corpuscles. S. B. S.

Oxycholesterol. E. SCHREIBER and LENÁRD (*Biochem. Zeitsch.*, 1913, **49**, 458—465).—This substance pre-exists as such in the blood. It is also found in the brain, lungs, heart, intestine, spleen, kidneys, muscles, sometimes in the pancreas. It is, however, not present in the liver. The failure to find the substance in this organ is shown not to be due to imperfect technique. Oxycholesterol is absent from the blood in diabetic coma. Preliminary experiments are described which are directed towards ascertaining the action of the liver towards oxycholesterol.   S. B. S.

The Nature of the Destruction of Hæmoglobin during the Autolysis of Organs. SOICHIRO MIURA (*Biochem. Zeitsch*, 1913, **49**, 137—143).—The disappearance of the blood pigment from autolysing mixtures, as observed by Hess and Saxl, is confirmed. This is not due to an enzyme in the mixture, but is a coagulative process, which takes place rapidly in the presence of chloroform, which is used as an antiseptic; the blood colour disappears from solution, in fact, when a solution is incubated with chloroform without the presence of any organ. The hæmatin component remains unchanged in quantity during the process of incubation. When organs are present, the coagulum is carried down with the solids.   S. B. S.

The Action of Leucocytes on Some Hexoses and Pentoses. III. Mechanism of Lactic Acid Formation from Carbohydrates. PHŒBUS A. LEVENE and GUSTAV M. MEYER (*J. Biol. Chem*, 1913, **14**, 149—154).—Leucocytes transform dextrose into *d*-lactic acid, but cleavage does not proceed further. There must be many intermediate stages in this change. Embden's view that glyceraldehyde is one is not confirmed. Moreover, regardless of the nature of the hexose (mannose, lævulose, galactose, dextrose), the lactic acid is invariably of the *d*-form. Whether pyruvaldehyde is the phase immediately preceding the formation of lactic acid remains to be established. Tissues preserved under aseptic conditions act similarly. Dissociation of pentoses by leucocytes does not occur.   W. D. H.

The Behaviour of Calcium in the Serum. PETER RONA and DENGO TAKAHASHI (*Biochem. Zeitsch.*, 1913, **49**, 370—380).—The dependence of the solubility of calcium on the hydrogen and hydrogen carbonate concentration was investigated. The values, according to the laws of mass action of $k_1 = [Ca^{..}][HCO_3]_2/[H_2CO_3]$ and $k_2 = [Ca^{..}][HCO'_3]/[H]$, were determined. The experimental method of determining these constants is given in detail, and the values $k_1 = 116·10^{-6}$ and $k_2 = 350$ were found. Serum was submitted to dialysis against an outer fluid of definite volume of known hydrogen carbonate concentration, and the composition of the inner and outer fluids was ascertained when equilibrium had been established. From the data thus obtained, the conclusion is drawn that the calcium hydrogen carbonate is in free diffusible form, but forms metastable supersaturated solutions. By the method of com-

pensation dialysis, against known phosphate mixtures, results were obtained indicating that the phosphate is also freely diffusible. The non-diffusible calcium appears therefore to exist in the form of calcium protein compounds. S. B. S.

Mode of Action of the Anti-coagulating Substance of the Plasma of Propeptone. HENRI STASSANO (*Compt. rend.*, 1913, **156**, 912—915).—A continuation of previous work (compare this vol., i, 418) on the coagulation of the plasma of propeptone. On diluting samples of the plasma with equal volumes of solutions of different chlorides of equivalent strength, the period of time, prior to coagulation, increases with rise in molecular weight of the chloride. Diminution of the saline concentration by dialysis, or marked increase of it by addition of sodium chloride, produces coagulation. Addition of a strongly negative colloid hastens coagulation. The following conclusions are drawn: (1) In the plasma of propeptone the coagulation, in vitro, takes place in two stages: activation of the fibrin-ferment, followed by its action on the fibrinogen. There is also a third stage, commencing when the colloidal stability of the fibrinogen is brought about, which consists in the appearance of granules in the uniform gel, this phenomenon being very fugitive and only visible under the ultramicroscope in the case of blood. (2) The anti-coagulating substance of the propeptone plasma forms a complex with the fibrinogen, hindering its precipitation and giving rise to a coagulum, without the intervention of one of the above-mentioned methods. W. G.

Digestion in the Chick. T. P. SHAW (*Amer. J. Physiol.*, 1913, **31**, 439—446).—Extracts of the glandular structures of the floor of the mouth in the chick contain an amylolytic enzyme active in an alkaline medium. This was found in extracts made an hour after hatching. The crop secretes no enzymes, but simply retains the food whilst salivary digestion goes on. By the second day, the gastric juice secreted contains proteolytic and milk-curdling enzymes which are active in an acid medium. The functions of the pancreas are imperfectly developed before the seventh day after hatching; the pancreatic juice then contains the usual three enzymes. The liver contains glycogen on the twentieth day of incubation; it becomes glycogen-free twenty-four hours after hatching if no food is given. It is found in the liver on the second day after the administration of starchy food. Lactose is not a glycogen-former in chicks, but acts as an irritant to the gastric and intestinal mucous membrane. W. D. H.

The Dependence of Lipase Action on the Concentration of the Hydrogen Ion. HEINRICH DAVIDSOHN (*Biochem. Zeitsch.*, 1913, **49**, 249—277).—The lipoclastic action was investigated by the stalagmometric method with the employment of tributyrin as substrate. The optimal action of the duodenal lipase of sucklings (withdrawn by means of a tube) was at $[H^{\cdot}] = 3.2 \times 10^{-9}$ or $p_H = 8.5$. A series of experiments was carried out with the same amount of

ferment in solutions of different hydrogen ion concentrations, and the course of lipolysis investigated. It was assumed that, except under optimal conditions, a fraction only of the ferment was active, and a method is given of calculating this fraction. If this amount is plotted graphically as a function of the hydrogen ion concentration, a curve is obtained which is identical with the dissociation curve of a weak acid, and is of the same order of magnitude as a curve deduced in a similar manner for trypsin. The conclusion is drawn that the lipase, like trypsin, is an amphoteric electrolyte with the acid dissociation constant $k_a = 1 \cdot 0 \times 10^{-7}$. The lipolytic activity is proportional to the amount of ferment ion present. The lipase of the stomach has a broad optimal zone with $[\dot{H}]$ between 10^{-5} and 10^{-4}. The curve obtained for this ferment is similar to the invertin curve, and is that of the residuary dissociation curve of an ampholyte with the constant $k_a = 4 \cdot 5 \times 10^{-7}$. The active principle of the stomach lipase is bound to the dissociation residue, and the optimal activity corresponds with the isoelectric point of the ampholyte, the basic dissociation constant of which is about 10^{-12}. There is therefore a difference between the gastric and duodenal lipases, which can be distinguished from one another by ascertaining the optimal $[\dot{H}]$ concentration for their action. There is no evidence in the case of sucklings of regurgitation from duodenum. The lipase of human milk is apparently a pancreatic lipase.

S. B. S.

Method of Investigating Metabolism in Rabbits, Milk being the Only Food. ERNST LAQUEUR (*Zeitsch. physiol Chem.*, 1913, **84**, 109—116) —A specially constructed cage for metabolism experiments on rabbits is described. For prolonged periods milk was the only nutriment given. The advantages of milk are that its nitrogen is easily estimated, the urine does not readily decompose, and its secretion is regular. The absorption of milk is rapid, and 95% of it is utilised as compared with 65—70% of oats and cabbage.

W. D. H.

Amino-acids and Sugar for Rectal Feeding HUBERT W. BYWATERS and A. RENDLE SHORT (*Arch. expt. Path Pharm.*, 1913, **71**, 426—445).—The older observations on the nutritive value of enemata are untrustworthy. Not a trace of milk or egg (peptonised for twenty to thirty minutes) is absorbed. Amino-acids, however, are absorbed, and lead to an increase in urinary nitrogen; the ammonia is low in the urine, hence the absorption of putrefaction products is absent. Dextrose is better absorbed than lactose; fat is badly absorbed. The best enema for rectal feeding is milk which has been subjected to pancreatic digestion for twenty-four hours plus 5% of dextrose.

W. D. H.

The Functions of the Liver in the Metabolism of Fats. I. HENRY S. RAPER (*J. Biol. Chem.*, 1913, **14**, 117—134) —Cocoanut oil given to cats or dogs by the mouth can be detected in the liver in five to six hours. The amount present does not exceed 6% of

that absorbed. If cocoanut oil soap plus glycerol and bile are injected into the intestine of anæsthetised cats, about 30% of the absorbed fatty acid is found in the liver. If an emulsion of the oil is given intravenously, 25—60% is found in the liver. During absorption the fat in the chyle contains fatty acids with an average higher molecular weight than in the oil. The lower acids are therefore partly absorbed as sodium salts. The volatile acids from the liver absorb more iodine than those from normal livers. The increase is not great, but it probably indicates that saturated fatty acids containing 10, 12, or 14 carbon atoms may become unsaturated in the liver.   W. D. H.

The Influence of Urea Administered by the Mouth on the Nitrogenous Metabolism of Pigs. EMIL ABDERHALDEN and ARNO ED. LAMPÉ (*Zeitsch physiol. Chem*, 1913, **84**, 218—222).—No evidence was found to support the view that urea in the food acts as a protein sparer. In reference to gelatin, attention is drawn to the fact that various commercial specimens yield as much as 1% of tyrosine, and may even yield tryptophan. It is evident that no certain conclusions as to the nutritive value of gelatin can be drawn from experiments with such variable material.   W. D. H.

Nitrogen Retention after Feeding on Urea. Reply to Abderhalden and Lampé EDUARD GRAFE (*Zeitsch. physiol. Chem.*, 1913, **84**, 234—238).—Polemical. The author maintains the correctness of his earlier conclusions.   W. D. H.

Influence of Caffeine on Creatine and Creatinine Metabolism WILLIAM SALANT and J. B. RIEGER (*Proc. Amer. Soc. Biol. Chem*, 1912-13, xxxv; *J. Biol. Chem*, **14**).—Caffeine causes a moderate increase in the urinary creatine in fed rabbits, but a large increase during inanition; in some experiments, however, neither creatine nor creatinine were affected. Experiments on dogs gave negative results.   W. D. H.

Metabolism of Nitrogenous Sugar Derivatives. JAMES ARTHUR HEWITT (*Biochem. J.*, 1913. **7**, 207—210). — Dextrose-*p*-phenetidide given by the mouth or by injection is not toxic in amounts up to 4 grams per kilo. of body weight. It produces no effect on nitrogenous metabolism, but a reducing substance appears in the urine. Some escapes oxidation in the body; *p*-phenetidine in amounts of 0·1 gram per kilo. of body weight is highly toxic.
                                        W. D. H.

The Action of Carbon Dioxide on Metabolism. Autolysis and Metabolism. VI. ERNST LAQUEUR (*Zeitsch. physiol. Chem.*, 1913, **84**, 117—160).—The nitrogenous metabolism was investigated on rabbits during a milk diet and inanition. Carbon dioxide slows and deepens the breathing; little or no narcotic action was observed. Nitrogenous metabolism was unaffected by a carbon dioxide percentage up to 7%. At 10% the output of nitrogen was increased,

at 13% very markedly so. In half the experiments this was accompanied by retention of water. The high tension of the gas is regarded as the cause of the increased decomposition of tissue-protein, possibly because the activity of autolytic enzymes is heightened.   W. D. H.

Synthetic Powers of Animal Cells. The Action of Sodium Nitrate on Nitrogenous Metabolism. EMIL ABDERHALDEN and PAUL HIRSOH (*Zeitsch. physiol. Chem.*, 1913, 84, 189—200).—Nitrogen given in the form of sodium nitrate is excreted quantitatively in the urine; it takes no direct part in protein metabolism. In two cases, however, there was retention of nitrogen, which did not correspond with the nitrogen given in the form of sodium nitrate. This is important as showing that nitrogen retention may be the result of the administration of nitrogenous materials which do not participate in metabolism.   W. D. H.

Utilisation of Ammonia Nitrogen in Protein Metabolism. ALONZO E. TAYLOR and A. L. RINGER (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xxvi—xxvii; *J. Biol. Chem.*, 14).—The findings of Grafe and of Abderhalden are confirmed, that starving and diabetic animals may retain a considerable part of the nitrogen ingested as ammonium carbonate.   W. D. H.

Nitrogenous Assimilation on Feeding on Small Amounts of Protein and Large Amounts of Ammonium Salts and Urea. EDUARD GRAFE (*Zeitsch. physiol. Chem.*, 1913, 84, 69—96).— The favourable action of ammonium salts and urea given by the mouth in pigs in causing retention of nitrogen is supported by further experimental data. By themselves, however, they do not maintain nitrogenous equilibrium over prolonged periods, but in combination with a small amount of protein they do. In other words, they have a protein sparing action. Whether their nitrogen is converted into protein or not is discussed, but no definite conclusion reached. The paper concludes with polemics against Abderhalden and Lampé, whose experiments are held to support and not disprove the author's contentions.   W. D. H.

The Location of Protein Synthesis and the Production of Nitrogenous Equilibrium with Minimal Amounts of Proteins of Varying Decomposibilities. HANS STECK (*Biochem. Zeitsch*, 1913, 49, 195—224).—It has been assumed that the chief seat of synthesis of proteins is in the mucous membrane of the small intestine. If this is the case, those proteins which most readily undergo enzymatic hydrolysis into their constituent amino-acids will be the most efficient in maintaining nitrogenous equilibrium (that is, will maintain equilibrium when ingested in the smallest quantity), provided that the energy needs of the organism are sufficiently satisfied by the caloric value of the fats and carbohydrates. The reason for this assumption is that the majority of the amino-acids necessary for protein synthesis will be present at

the same time in the intestine in those proteins which are readily hydrolysed. The method of experiment adopted by the author was to place himself on a diet of sufficient caloric value and nearly free from nitrogen, and then to estimate the nitrogen loss. On this diet various proteins were superimposed, and the quantity was ascertained in each case, which is just necessary to restore the nitrogenous equilibrium. It was found that after three days of protein-free diet, the superimposition of small quantities of beef, egg-albumin, and caseinogen could restore equilibrium, but the amounts bore no relationship to their decomposability by proteoclastic ferments. The conclusion is drawn therefore, that protein synthesis takes place in parts of the organism other than the small intestine. From the amounts of nitrogen secreted in the after period, it appears that the ingestion of these proteins results in protein synthesis in the organism. Hæmoglobin, when ingested in small quantities, was inefficient in maintaining nitrogenous equilibrium. S. B. S.

The Influence of the Plane of the Protein Intake on Nitrogen Retention in the Pig. ELMER V. McCOLLUM (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xxxiii—xxxiv; *J. Biol. Chem.*, 14). —The retention of nitrogen at all levels, except 7·5 times the endogenous level, was in close agreement, whether the proteins given were derived from wheat, oats, or maize. At five times this level, 10% of the ingested nitrogen was retained; at 7·5, 12—17%; at 10, 15, and 20, the retention was 21—24%. W. D. H.

Metabolic End-Products of the Lipoid Nitrogen of Egg-yolk. ELMER V. McCOLLUM and H. STEENBOCK (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xliv—xlv; *J. Biol. Chem.*, 14).—A pig was fed for a week on 220 grams of dry egg-yolk and 35 grams of starch per diem. The nitrogen intake was 11·65 grams daily; of this, 0·65 gram was lipoid nitrogen. The urinary nitrogen varied from 5 to 6 grams; of this 30 to 40% was in the form of ammonia, and only 35—45% as urea. The urine contained 0·3 gram of nitrogen as substituted amines. The demethylation of substituted amines is evidently not readily accomplished in the pig's body. W. D. H.

The Biological Value of a-Nucleic Acid. G. ALLESANDRO BROSSA (*Chem. Zentr.*, 1912, ii, 2123; from *Arch. Anat. Physiol.* (*Physiol. Abt.*), 1912, 191—196).—A dog and two hens were reduced to a nitrogen-free diet balanced by increased amounts of carbohydrates and fats, and then supplied with a-nucleic acid. Estimation of nitrogen in the excreted substances showed that 60—80% of the nucleic acid, a compound which is far removed from the proteins, had been absorbed. J. C. W.

Resorption of Bromide from the Intestine. STEFAN VON BOGDÁNDY (*Zeitsch. physiol. Chem.*, 1913, 84, 15—17).—To study the resorption of bromide from the intestine, the blood stream was limited to the intestine, heart, and lungs, and the haloids in it determined before and after injection of sodium bromide. The

bromide is shown to aggregate in the blood in a very short interval; part of the sodium chloride of the blood is replaced by bromide.

<div align="right">E. F. A.</div>

The Fate of Protein Cleavage Products in the Intestine.

EMIL ABDERHALDEN, ARNO ED. LAMPÉ, and EFIM S. LONDON (*Zeitsch. physiol. Chem.*, 1913, **84**, 213—217).—Accepting the view that in absorption protein cleavage products enter the blood stream as amino-acids and ammonia, there still remains the possibility that the lacteals may be a channel for protein absorption. In two series of experiments on dogs, the lymph during digestion of meat was found to contain more nitrogen but less amino-acid than during hunger; the amount of ammonia was but little altered. Further work in this direction is promised.

<div align="right">W. D. H.</div>

The Absorption of Magnesium Sulphate Solutions in the Small Intestine, and the Mode of Action of Saline Purgatives.

RUDOLF COBET (*Pflüger's Archiv*, 1913, **150**, 325—360).—The relative importance of physical and physiological factors in the causation of purgation by salines is discussed. Magnesium sulphate causes a great increase of secretion in the intestines; the sodium chloride of the intestinal juice poured out is re-absorbed in the lower reaches of the gut, but the fluid portion is not; the sulphate itself is badly absorbed.

<div align="right">W. D. H.</div>

Intestinal Obstruction. A Toxic Substance in the Intestinal Mucosa.

GEORGE H. WHIPPLE (*Proc. Amer. Soc. Biol. Chem.;* 1912–13, xxxii—xxxiii; *J. Biol. Chem.*, **14**).—Closed loops of the small intestine yield what normal mucosa does not yield, a toxic substance which causes low blood-pressure, vomiting, diarrhœa, collapse, and death. If the mucosa is first destroyed by sodium fluoride, no toxic substance is formed.

<div align="right">W. D. H.</div>

The Influence of Function on the Lime Requirements of Animals.

H. STEENBOCK and EDWIN B. HART (*J. Biol. Chem.*, 1913, **14**, 59—73).—In the non-pregnant animal a daily intake of 0·3 gram of CaO in the pig, and 0·4 in the goat per 100 lbs. of body-weight covers metabolic losses; but mammary activity is a severe drain on the skeletal lime, and the allowance in the food should be three or, better, six times greater, for increase of food entails large losses of lime in the intestine.

<div align="right">W. D. H.</div>

The Effect of a High Magnesium Intake on Calcium Retention in Swine.

EDWIN B. HART and H. STEENBOCK (*J. Biol. Chem*, 1913, **14**, 75—80).—Bran is not a good bone producer, on account of its low lime content. Magnesium salts added to a pig's ration increase the urinary calcium, but this is counteracted by di-potassium hydrogen phosphate. The inter-relations existing between the mineral elements are important factors in nutrition.

<div align="right">W. D. H.</div>

The Behaviour of Plasteins in the Animal Body. ERICH VON KNAFFL-LENZ and ERNST P. PICK (*Arch. expt. Path. Pharm.*, 1913, **71**, 407—425).—Plasteins act as antigens, but the immune material generated is not specific. The specificity of the original proteins is thus destroyed during digestion. It further makes no difference what variety of pepsin is employed in their formation. Plasteins do not produce the phenomena of anaphylaxis.

W. D. H.

The Influence of the Composition and Amount of the Mineral Content of the Ration on Growth. ELMER V. MCCOLLUM and MARGUERITE DAVIS (*Proc. Amer. Soc. Biol. Chem.*, 1912-13, xl; *J. Biol. Chem.*, **14**).—Young rats do not grow when fed on wheat kernel only, but the addition of salts so as to make the ration like that of milk or egg-yolk produced normal growth.

W. D. H.

The Chemical Changes Occurring in Meats during Drying in a Vacuum. L. H. DAVIS and A. D. EMMETT (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xlii; *J. Biol. Chem.*, **14**).—Calculating the data for fresh and desiccated meats to the dry basis, using the two values for dry substance (the vacuum and the oven-heated), the results agree closely for the various constituents, the differences being greatest in the fat, as was to be expected. W. D. H.

The Presence of Choline or Allied Bases in the Saliva of the Horse. JULES HOUDAS (*Compt. rend.*, 1913, **156**, 824—826) — Schulze and Trier (A., 1912, ii, 1203) having demonstrated the presence of choline and allied bases in all plants, the author has examined the saliva of horses for the presence of these substances therein, using Bouchardat's reagent to recognise them. Specimens of saliva were obtained from horses under varying conditions and at different times after feeding and with varying diet, and in all cases either choline or bases of the same group were found to be present. W G.

The Central Nervous System under Normal and Pathological Conditions. V. Biochemical Studies on Brain Swelling : (*a*) Acute Brain Swelling and the Colloidal Theory of Œdema. GIACOMO PIGHINI, PIETRO BARBIERI, and DOMENICO CARBONE (*Biochem. Zeitsch.*, 1913, **49**, 293—316).—According to the theory of M. Fischer, œdema is due essentially to imbibition of water, which, in the case of proteins, takes place more readily in the presence of alkalis and bases, and is inhibited by salts. The authors discuss the subject of brain swelling from the clinical and pathological point of view, and suggest as a possible cause for the imbibition of water by the brain an increase of acid in the circulation. They have, however, failed to substantiate the hypothesis, as the injection of acids under varying conditions into animals (rabbits) did not produce œdema. S. B. S.

The Fatty Acids of the Human Brain. EGERTON CHARLES GREY (*Biochem. J.*, 1913, **7**, 148—156).—At least 25% of the solid fatty acids of the brain are hydroxy-acids; of these, three have been isolated: $C_{17}H_{34}O_3$ or $C_{22}H_{44}O_4$, m. p. 100—101°; $C_{25}H_{50}O_3$, m. p. 91·0°; and $C_{20}H_4O_3$, m. p. 73·5°, and two at least are mono-hydroxy-acids, and therefore are not produced artificially by oxidation of unsaturated fatty acids. The unsaturated acids include oleic, linoleic, and linolenic acids; also an acid still more unsaturated, to which the name *clupanodenic acid* is given; it combines with 12 atoms of bromine. Another is a solid, $C_{18}H_{34}O_2$ or $C_{18}H_{36}O_2$, m. p. 42°; this is probably an isomeride of oleic acid. The saturated acids are stearic, palmitic, myristic, and Thudichum's neurostearic acid, m. p. 51—52°. The resemblance between the hydroxy-acids of the brain and those of lanoline is additional evidence of the relationship of nervous tissues to other tissues of epiblastic origin.

W. D. H.

Action of Various Influences on the Mammalian Heart V. H. K. MOORHOUSE (*Amer. J. Physiol.*, 1913, **31**, 421—438).— Isolated strips of the cat's auricle beat spontaneously in a bath of oxygenated Ringer's solution; the rhythm and effect of temperature are approximately equal in coronary, nodal, and septal strips. Drugs which act on the vagus are more effective on strips which do not contain nodal muscle. Drugs which act on sympathetic nerve-endings produce an equal effect on all these kinds of strip, but the acceleration lasts longest in septal strips. The sino-auricular node does not exhibit any specially reactive properties to various influences affecting rhythm.

W. D. H.

The Action of Oxalic Acid on the Frog's Heart. OSKAR GROS (*Arch. expt. Path. Pharm.*, 1913, **71**, 395—406).—A solution of sodium oxalate added to Ringer's solution soon stops the heart of the frog in diastole. Its activity is restored by washing out with a calcium-free solution. Sodium citrate acts more powerfully in the same way, although its power to precipitate calcium is less. It is held that the removal of the calcium is not the cause of the action, but that oxalates and citrates have a specific harmful effect on cardiac tissue.

W. D. H.

Diastases. II. Sugar Formation in the Frog's Liver. I. IVAR BANG (*Biochem. Zeitsch.*, 1913, **49**, 40—86).—The experiments were carried out with both *Rana esculenta* and *R. fusca*. Sugar was estimated in separate lobes of the liver. As a rule, one lobe was separated from the others, and the sugar was estimated immediately, whilst the other lobes were allowed to remain in Ringer's fluid and the sugar was estimated after several hours. The amounts of sugar free and existing in the separate lobes from the same animal were also ascertained, and the limits of variation determined. From the alterations in weight after keeping in Ringer's solution, which were found to be small, the conclusion was drawn that the liver still survives even after prolonged keeping in the Ringer

fluid, it being assumed that the organ is not killed, whilst its osmotic properties remain intact. Other reasons are also given for assuming that the organ survives after prolonged immersion in Ringer's solution. After keeping in this liquid, the livers show an increase of reducing sugar (found both in the organ itself and in the fluid in which it is immersed), the amount of which is larger than the variations in the lobes from the same animal. The conclusion was therefore drawn that the surviving liver is capable of producing sugars. The mechanism of this sugar production was studied. It is not due to the diastase of the blood, as there is no appreciable difference between the amounts produced in a liver containing blood and one that has been perfused (from the portal vein). There is, however, a considerable difference between the sugar production by the crushed liver paste and by the intact cells, according to whether the organs have been perfused or not. If they have not been perfused, the paste produces much more sugar, owing to the fact that the diastase of the blood can then act; where they have been perfused, the difference between the sugar production by the paste and intact cells is very much diminished. This is additional evidence of the fact that the sugar production by the surviving liver is not due essentially to the diastase of the blood. The facts indicate that it is due to a liver enzyme. In the case of *Rana esculenta*, the treatment of the liver with alcohol reduces the sugar-producing power of the liver, which can, however, be restored by addition of sodium chloride; in fact, when the liver has been treated in this way, the sugar-producing power is increased beyond that of the original intact liver. This fact is explained by the hypothesis that the alcohol removes some lipoid-like substance which exerts an inhibitory action on the sugar-producing power. As the addition of the alcoholic extract does not inhibit this power exerted by the extracted liver and salt, it is assumed that the inhibitory substances only exert their action when in some form of combination, which is broken up on treatment with alcohol, but not restored on the addition of the alcoholic extract. The same phenomena were not observed in the livers of *R. fusca*, which, unlike those of *R. esculenta*, do not appear to contain a large store of enzyme or pro-enzyme, which can be activated by the addition of salt.   S. B. S.

Diastases. III. Sugar Formation in the Frog's Liver. II. IVAR BANG (*Biochem. Zeitsch.*, 1913, **49**, 81—119).—Adrenaline increases the sugar-producing power of the liver, in quantities which are insufficient to kill the organ. Details are given of Overton's experiments on the irritability of muscles after treatment with adrenaline which justify the conclusion as to the relative non-toxicity of the adrenaline solutions employed. A detailed account is given of the action of adrenaline on the sugar production of the liver under varied conditions. In the case of *R. fusca*, the increased production appears to be due to the reduction of the acidity of the medium, and the effect can be imitated by the use of neutral phosphate solutions. Furthermore, the accelerating effect of the adrena-

line in these cases can be antagonised by the presence of minute amounts of free hydrochloric acid. In the case of *R. esculenta*, the action of adrenaline appears to be exerted on the intracellular lipoids, which in combination inhibit the diastatic action of the organ (compare preceding abstract). The adrenaline action in this case can be imitated by treating the liver with narcotics (for example, alcohol), which can also break down the lipoid complex. There is no evidence that adrenaline causes new production of enzyme; it appears only to activate the pre-existing ferment.

S. B. S.

The Formation of Glycogen from Glyceraldehyde in the Liver. JAKOB PARNAS (*Zentr. Physiol.*, 1912, 26, 671—672).— Perfusion of the tortoise's liver with glyceraldehyde in Ringer's solution leads to the deposition of glycogen therein, at the rate of about 50 mg. reckoned as dextrose per hour per 10 grams of liver. Whether this is due to condensation, or oxidation through the stages of glyceric acid, glycolaldehydecarboxylic acid, and glycol-aldehyde is uncertain; the view that dextrose is katabolised into glyceraldehyde in the body is also unsettled.   W. D. H.

The Importance of Cholesterol in the Organism. LEON-HARD WACKER and WEBNER HUECK (*Arch. expt. Path. Pharm.*, 1913, 71, 373—394).—The methods of estimation of cholesterol are dis-cussed, but the microscopic examination of the adrenal cortex gives a good indication of the amount present. In this situation free cholesterol is an integral and stable cell constituent, but the chole-sterol in the condition of ester is variable and labile. It is here that the polarising microscope is especially useful. In arterial sclerosis, chronic kidney disease, diabetes, and during pregnancy the amount of cholesterol esters increases, but in long-continued infectious disease, septic processes, chronic ulcer, cancer, and tubercle it falls. In the acute stages of infectious diseases, it increases. The amount in the blood varies directly as that in the suprarenal; this is regarded as important, for cholesterol plays a rôle in the natural protective processes of the body.   W. D. H.

The Iodine-containing Complex of Thyreo-globulin. FRED C. KOCH (*J. Biol. Chem.*, 1913, 14, 101—116).—The full activity of thyroid tissue (measured by Hunt's method) is contained in the thyreo-globulin fraction. The full activity per iodine unit is still present in the metaprotein fraction from this globulin, although the iodine in this fraction is increased three-fold. Other products of hydrolysis (proteoses and iodothyrin) show a decrease in activity per unit of iodine. The amino-acid fractions contain very little iodine, and are either inactive or nearly so. Tetra-iodohistidine anhydride and iodotryptophan have no activity.   W. D. H.

Some Phosphatides of Human Placenta. I. and II. C. SAKAKI (*Biochem. Zeitsch.*, 1913, 49, 317—325, 326—332).—The placenta was extracted with alcohol at 60°. A white substance

only sparingly soluble in cold alcohol was isolated, which was very similar in properties to the diaminophosphatide isolated by Thierfelder and Stern from egg-yolk. Its composition was intermediate between that of *apo*myelin and sphingomyelin, as isolated by Thudichum. A preliminary account of other products is given. No evidence as to the existence of jecorin was obtained.

In the second paper, a preliminary account is given of various fractions, none of which can be claimed to be a pure product.

<div align="right">S. B. S.</div>

Muscular Contraction ; Influence of Non - electrolytes, Electrolytes, and Osmotic Pressure. GEORGES KLEEFELD (*Bull. Acad. roy. Belg.*, 1913, 91—180).—The principal views of J. Loeb on the antagonism between calcium ions and those of potassium and sodium, as well as on the toxicity of sodium ions, are confirmed; perfusion with calcium chloride extinguishes muscular excitability; sodium nitrate has the same effect, and potassium is sometimes indifferent; at other times it abolishes excitability. Certain non-electrolytes (sucrose, dextrose) are capable of determining rhythmic contractions. Calcium is sometimes an excitant of contractility, and is able to render contractile muscles treated with sodium citrate. Calcium can exist in the perfusion fluids far above the normal amount without suppressing excitability. By the method of Lapicque-Weiss it can be shown, however, that electrical irritability can diminish, even although the muscle executes normal contractions. Contractility and irritability cannot be regarded as identical.

<div align="right">W. D. H.</div>

Amount of Creatine in Muscles of Various Animals and in Different Types of Muscles. MARIO CABELLA (*Zeitsch. physiol. Chem.*, 1913, 84, 29—38).—Creatine is always present in the muscle tissue of vertebrates. The amount varies with the nature of the muscle; it is most in striped voluntary muscle, less in heart muscle, and least in unstriped muscle. In birds (hens, ducks) the amount of creatine in the breast muscles is considerably larger than that in the limb muscles.

Similar differences in the amount of creatine are found in the individual muscles of any one animal. These differences persist whether referred to the weight of fresh muscle or dried muscle, or expressed as creatine nitrogen in terms of the total nitrogen. This nitrogen factor lies between 3 and 4 for the voluntary muscles of mammals, birds, fishes, and the heart muscle of the ox. It is from 4 to 5 for the breast muscle of birds, and about 1 for the heart muscle of the hen and the smooth muscle of the ox.

Creatine could not be obtained from the muscular tissue of the mantle or the arms of the octopus.

<div align="right">E. F. A.</div>

Muscle-Creatine. Dialysis of Creatine from Dog's Muscle H. T. LEO and PAUL E. HOWE (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xliii ; *J. Biol. Chem.*, 14).—Creatine dialyses out from muscle into water, Ringer's solution, and various strengths of sodium chloride

solution. Hydrochloric acid delayed the diffusion, alcohol increased
it. The experiments offer no definite evidence as to the way in
which creatine is held in the muscle.   W. D. H.

The Action of Potassium Chloride on Frog's Muscle.
RICHARD SIEBECK (*Pflüger's Archiv*, 1913, **150**, 316—324).—Neutral
isotonic solutions of potassium chloride render muscles rapidly inex-
citable; the muscles increase in weight. Even after some hours,
when there is a 20% increase in weight, the action is completely
reversible. Organs the structure of which is destroyed by freezing
and thawing, do not swell in solutions of potassium chloride, but
swell in alkaline solutions. An acid reaction causes in muscle either
in Ringer's or a potassium chloride solution no marked reversible
effect; but the swelling is increased by faradic stimulation, an
alkaline reaction, or by narcosis.   W. D. H.

Connective Tissues of Limulus. HAROLD C. BRADLEY (*Proc.
Amer. Soc. Biol. Chem.*, 1912–13, xl—xli; *J. Biol. Chem.*, 14).—The
cartilage-like tissue yields a sclero-protein which is insoluble in
water and the ordinary solvents. It is insoluble in pepsin hydro-
chloric acid, but digests readily in a tryptic mixture. It gives the
usual protein reactions, but no gelatin was obtained. The white,
fibrous tissue within the carapace is also composed of a non-
collagenous sclero-protein. It digests readily in a peptic, but very
slowly in a tryptic, mixture.   W. D. H.

The Secretion of Pigments by Annelids. K. KSCHISCHKOWSKI
(*Chem. Zentr.*, 1913, i, 40; from *Zentr. Physiol.*, 1912, **26**, 528—532).
—Under certain conditions, *Lumbriconereis impatiens* secretes a
lilac-red pigment, which gives an orange solution in ether and a
pink in chloroform. The secretion is provoked in a specific way by
solutions of potassium salts which are isotonic with a 3·5% solution
of sodium chloride. If the organisms are narcotised or kept in
isotonic solutions free from potassium salts for some time, the
pigment reaction does not occur for several days.   J. C. W.

The Rôle of Glycogen, Lecithides, and Fats in the Repro-
ductive Organs of Echinoderms. BENJAMIN MOORE, EDWARD
WHITLEY, and ALFRED ADAMS (*Biochem. J.*, 1913, 7, 127—141).—The
male and female reproductive glands in echinoderms contain large
amounts of reserve metabolic products, such as glycogen, fat, and
lecithides. These reserves are only slowly used up, if at all, when
the animal is deprived of food. In such glands no sugar forma-
tion occurs in a period of two days after death. The fatty sub-
stances are highly unsaturated, thus resembling liver oils.

W. D. H.

The Basic and Acidic Proteins of the Sperm of Echinus
esculentus. Direct Measurements of the Osmotic Pressure
of a Protamine or Histone. BENJAMIN MOORE, EDWARD WHITLEY,
and ARTHUR WEBSTER (*Biochem. J.*, 1913, 7, 142—147).—A substance

was separated from the ripe male gonads of *Echinus esculentus*, which had properties intermediate between those of a histamine and a histone. Its molecular weight calculated from its osmotic pressure is 8780. Its action on ova and cell division was tested, but the results were negative. W. D. H.

Anoxybiose and Chemical Polarity. (Mme.) ANNA DRZEWINA and GEORGES BOHN (*Compt. rend.*, 1913, 156, 810—812).—*Prostheceraeus* and *Convoluta* when placed in tubes deprived of oxygen for six hours and then returned to aerated water, in all cases exhibit the phenomenon that the anterior extremity has possessed a greater resistance to the privation of oxygen than the posterior extremity, the latter becoming disintegrated when returned to water, whilst the heads live and can be seen swimming about. This differentiation the authors compare with chemical polarity. W. G.

The Composition of Human Bile. ERNST VON CZYHLARZ, ADOLF FUCHS, and OTTO VON FÜRTH (*Biochem. Zeitsch.*, 1913, 49, 120—129).—Details are given for the estimation of the following constituents of the bile: Total solids, pigment (colorimetric method), cholesterol (colorimetric method with chloroform and acetic anhydride), higher fatty acids, mucin, bile acids (as cholic acid). Typical analyses are given of bile obtained from the bladder and from fistulæ. Administration of cholesterol *per os* appeared to increase, not the amount of cholesterol, but that of the bile acids in the bile obtained from a fistula. S. B. S.

Secretin and Vaso-dilatin. L. LAUNOY and KARL OECHSLIN (*Compt. rend.*, 1913, 156, 962—965).—By repeated precipitation by absolute alcohol from aqueous solution the authors have obtained the secretin of Bayliss and Starling (A., 1902, ii, 275, 613; 1903, ii, 316) in a solid state as a non-hygroscopic, white powder, very soluble in water, having an alkaline reaction and a very marked exciting influence on the secretion of pancreatic juice, but no depressing effect. Further, on concentrating the alcohol used for the above precipitation, they obtained a yellow, hygroscopic powder, soluble in water, and having a strongly alkaline reaction. Its aqueous solution only produces feeble secretion excitation, but is strongly depressant. It corresponds with the "depressor substance" mentioned by Bayliss and Starling (*loc. cit.*). This shows that Popielski's vaso-dilatin (compare A., 1912, ii, 593) is distinct from the above secretin. W. G.

An Attempt to Estimate the Vitamine-fraction in Milk. CASIMIR FUNK (*Biochem. J.*, 1913, 7, 211—213) —In milk freed from protein the vitamine fraction is precipitable by phosphotungstic acid; the amount of vitamine ($C_{17}H_{20}O_7N_2$) is about 1 to 2·5 mg. per litre. The filtrate still contains nitrogen, which probably represents allantoin. If milk is freed from fat by the centrifuge, about half the vitamine and allantoin is lost. Both allantoin and vitamine are destroyed by boiling. W. D. H.

The Secretion of the Two Kidneys. RAPHAEL LÉPINE and
RAYMOND BOULUD (*Compt. rend*, 1913, **156**, 754—756). — An
examination of the amount of urine flowing from each of the
kidneys of a healthy dog and a determination of the urea, sugar,
and chlorides present in each case. In every case there was a
greater flow from the right side, and the urine from·this side was
richer in chlorides and sugar. The nitrogen-urea coefficient was
the same for both sides. These differences are stated to be due
partly to a difference in the secretion activity, but principally to
differences in resorption of the urinary constituents by the two
kidneys.   W. G.

The Extremes of Variation of the Concentration of
Hydrogen Ions in Human Urine. LAWRENCE J. HENDERSON and
WALTER W. PALMER (*J. Biol. Chem.*, 1913, **14**, 81—85).—After a
dose of 10 grams of monosodium phosphate there is a slight increase
of hydrogen ion concentration in the urine. Larger quantities of
acid phosphate or of hydrochloric acid produce a similar effect, but
the acidity is never as great as in many pathological conditions. A
more alkaline urine is produced by sodium hydrogen carbonate, but
beyond a certain point even after large doses of alkali the reaction
of the urine does not change. In a large number of observations
the highest acidity exceeded 4·70; the highest alkalinity 8·70. This
corresponds with a range of 1:10,000 in the concentration of
hydrogen and hydroxyl ions. The actual variation in normal people
is at least 0 5 gram-molecule. In pathological states the variation
is greater. In most acid urines, the urinary acids are in large
measure free; in most alkaline urines they are almost completely
combined with bases.   W. D. H.

Diastase in the Urine of Infants. ERNST MAYER (*Biochem.
Zeitsch.*, 1913, **49**, 165—167).—Diastase is seldom completely absent
from the urine of breast-fed children. In the first three months,
however, it does not exceed 5 units (in Wohlgemuth's system).
There is no appreciable increase in the next three months. Between
the sixth and ninth month the values vary between 2·5 and more
than 20 units, after which period higher values are obtained. The
amount is, however, affected by pathological complications.
                                                           S. B. S.

Excretion of Purine Katabolites in Sundry Types of Mam-
malia. MAURICE H. GIVENS and ANDREW HUNTER (*Proc. Amer. Soc.
Biol. Chem.*, 1912—13, xxiv—xxv; *J. Biol. Chem.*, **14**).—Allantoin
is a regular constituent of the urine of rabbit, horse, pig, cow, cat,
dog, coyote, monkey, and man. To this list may be added the
opossum, guinea-pig, porcupine, sheep, and racoon. In man the
figure is smallest. Uricolytic power is greatest in carnivora; then
follow rodents, ungulates, and marsupials in the order named. It
is practically absent in man.   W. D. H.

Estimation of Amylolytic Ferments in the Urine as a
Measure of Certain Pathological Conditions. DUDLEY CORBETT
(*Quart. J. Med.*, 1913, **6**, 351—383).—The amount of ferment passed

by a given individual in twenty-four hours' urine is fairly constant, varying between 6·6 and 33 Wohlgemuth units, the average being 10—20°. It is also present in blood serum, the average amount being 10 units. The quantity in the urine is unaffected by the diet, the reaction of the urine, the presence of bacteria, and other abnormal constituents, with the exception of blood. The amount in the urine does not appreciably diminish if the urine is kept in the presence of toluene. The amount in the urine of an infant fed on milk is very small, but rises on the administration of starchy food. When the amount of ferment in the serum exceeds that of the urine, there is a renal deficiency, as the ferment is readily excreted by normal kidneys. High readings were never obtained in pure cases of renal disease. High readings (up to 100 or even more) were found in certain acute infective conditions, in pancreatic disease, in certain forms of eclampsia, and in one case of " acidosis " in a child. All cases of undoubted pancreatic disease, whether due to malignant or inflammatory processes, gave high readings, and the test may therefore be of value for diagnosis of such conditions. In diabetics on strict diet, the readings were generally subnormal. In severe cases the readings were lower than in the milder forms, but in these conditions the excessive amount of urine excreted must be taken into account. S. B. S.

Sarcolactic Acid and the Theory of Diabetes. R. T· WOODYATT (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xxxviii ; *J. Biol· Chem.*, 14).—A theory is proposed that the internal secretion of the pancreas dissociates dextrose and perhaps other hexoses, and that the presence of lactic acid is evidence of such dissociation. In pancreatic diabetes there is lessened dissociation and less lactic acid in the tissues. W. D. H.

The Behaviour of Blood Sugar in Normal and Pathological Cases. VII. The Blood Sugar in Diabetes Mellitus. FR. ROLLY and FR. OPPERMANN (*Biochem. Zeitsch.*, 1913, 49, 278—292. Compare this vol., i, 425).—No direct relationship was found between the amount of blood-sugar and glycosuria in diabetes. It was found that only in the case of severe diabetes did ingestion of proteins cause a rise both of blood-sugar and glycosuria. The blood sugar content did not increase either in the case of carnivora (dogs) or herbivora after administration of proteins. The administration of meat and carbohydrate foods caused a greater amount of glycosuria in diabetics than a similar diet in which the meat was replaced by vegetable proteins. S. B. S.

Sulphur Metabolism. I. The Urinary Sulphur Partition in Various Diseases. N. STADTMULLER, MAX KAHN, and JACOB ROSENBLOOM (*Proc. Amer. Soc. Biol. Chem.*, 1912–13, xliv; *J. Biol. Chem.*, 14).—High proportions of neutral sulphur were passed in nearly all cases of diabetes, in all cases of cancer, in one case of nephritis (out of two), and in the one case examined of hypopituitarism. W. D. H.

The Intestinal Flora. The Possible Production of Ptomaines in Acid Medium. ALBERT BERTHELOT and D. M. BERTRAND (*Compt. rend.*, 1913, **156**, 1027—1030. Compare A., 1912, ii, 668).—*Bacillus aminophilus intestinalis*, sown on media containing histidine and peptone, to which were added, instead of dextrose, amounts of lactic acid varying from 0·5 to 5 per 1000, shows marked culture and formation of 4-β-aminoethylglyoxaline, even with 3 per 1000 of acid present. Thus, in the intestinal flora of persons exhibiting, at the same time, symptoms of enteritis and colitis, their fæces being acid, the *B. aminophilus* may be found capable of attacking histidine even in a slightly acid medium. This bacterium is capable of acting in the intestine as a simple lactic ferment without forming any toxic base, but it can, in certain cases, produce aminoethylglyoxaline equally well in neutral or alkaline medium, or in the presence of acids elaborated by other microbes, and its attack is not limited solely to histidine.   W. G.

The Action of Aloin on Metabolism. The Physiology of Artificially Produced Gout and Fever. M. BERRÁR (*Biochem. Zeitsch.*, 1913, **49**, 426—446).—It has already been shown by Kossá, that administration of aloin to birds produces increased output of uric acid, which, in cases where the action of the kidneys is inefficient, leads to the production of an artificial gout. The researches on aloin have now been extended to mammals. Quantities of 0·1 to 0·2 gram per kilo. of body weight, administered to dogs, produces an increase of temperature and increased metabolism, which at the height of action can be double the normal. Both the gaseous metabolism and the output of various products in the urine and fæces were investigated. The substances forming the source of the increased energy production were those most readily at the disposition of the organism at the time of the administration of the drug. In the starving animal, the fat and proteins served chiefly for this purpose, whereas in the case of an animal which had received a diet rich in carbohydrates, these substances were mostly drawn upon, their metabolism increasing from 150 to 500%, the normal value. No distinct relationship was ascertained between the amounts of different products employed to meet the increased energy needs.   S. B. S.

Use of the Oxydase Reaction in the Differentiation of Acute Leucæmias. JOHN SHAW DUNN (*Quart. J. Med.*, 1913, **6**, 293—308).—The occurrence of a positive indophenol-oxydase reaction in large, non-granular cells in acute leucæmia is a certain proof of their myeloid nature, and enables a diagnosis of acute myeloid leucæmia to be readily made from a blood examination. The reaction is negative in the more embryonic forms of marrow-cells, and in small myoblasts, and is probably always negative in the most typical stage of large myoblasts with uniformly dense basophil reticular protoplasm. When the reaction is positive in these large, non-granular cells, it is associated with alterations in the protoplasm, which are recognisable by ordinary staining

methods, and indicate stages of ripening towards the granular myelocytes. Cases of acute myeloid leucæmia may occur in which the type of blood-formation is so embryonic that the oxydase reaction is valueless for differential diagrams; but even in such cases the histological characters of the large leucocytes may render a diagnosis possible. S. B. S.

Narcosis. BRUNO KISCH (*Zeitsch. Biol.*, 1913, **60**, 399—456).— The action of photodynamic materials (eosin, methylene-blue) is increased in *Colpidia* by the addition of alcohol, ether, or chloroform. Dilute alcohol, however, acting for short periods, sometimes has the opposite effect so far as eosin is concerned. Narcosis in these animals is markedly affected by light. In *Spirostomum* the action of increased oxygen tension is increased by light, and there is a rise in the oxygen consumed in *Oʃalɪno*. The effect of light and oxygen on *Spirostomum* is inhibited by narcotics, but this is not seen in *Opalina*. The movements of these animals are paralysed by narcotics, but not in a reversible way. W. D. H.

Gastric Juice in Malignant and Non-malignant Diseases of the Stomach and Duodenum. SAMUEL B. SCHRYVER and CHARLES SINGER (*Quart. J. Med.*, 1912, **6**, 71—81; 1913, **6**, 309—350).— Hans Fischer and Neuberg have suggested that the capacity of gastric juice to hydrolyse glycyl-tryptophan is diagnostic of cancer. The authors have investigated the action of gastric juices on Witte's peptone, and have shown, by the use of Sörensen's formaldehyde titration method, that in certain cases the gastric juice contains a peptolytic ferment. This was found in about $6\frac{1}{2}\%$ of the cases examined, all of which were taken from patients suffering from grave gastric disorder. It is only found when free hydrochloric acid is absent, and where the peptic powder is low, or even absent. It is not diagnostic of malignancy, as in the majority of cases of undoubted cancer the ferment was absent. It is most commonly associated with gastric dilatation and atrophy of the walls of the stomach, and is probably of intracellular origin.

Investigations were also carried out with the object of interpreting the analyses of gastric juice as regards the titration numbers obtained when methyl-orange and phenolphthalein are used as indicators. If B denotes the number of c.c. of $N/10$-sodium hydroxide necessary to neutralise 10 c.c. of gastric juice to phenolphthalein, and C the number of c.c. of alkali required to neutralise the same amount to methyl-orange, and A the number of c.c. of $N/10$-ammonia produced when 10 c.c. of the juice are incinerated by Kjeldahl's method with sulphuric acid, then $(C-B)/A$ was found to be a constant for any given amino-acid or mixtures of amino-acids or digestion products. $(C-B)/A \times 10$ has been designated the "nitrogen factor," and this is approximately a constant, and equal to about 2·4 for all cases of normal gastric juice. It is higher than that of gluten which has been digested for about one hour with pepsin in $N/20$-hydrochloric acid and pepsin of the same strength as that normally found in gastric juice, but is about equal to that

of a digest of an Ewald test-meal produced under similar conditions. The results indicate that the hydrochloric acid is not excreted in the form of an organic precursor. In cases of pyloric obstruction the "nitrogen factor" rises to 2·8 and more, and these high numbers are practically diagnostic for this condition. In cases of carcinoma of the body of the stomach, free mineral acid is absent, and pepsin is almost always absent, the analyses indicating almost complete achylia. In ulcers of the body of the stomach, the analyses vary, but complete achylia, such as is found in cases of carcinoma, is infrequent. Sometimes the analyses in this condition are not far removed from normal. In cancer of the pylorus, as opposed to cancer of the body of the stomach, the analyses are generally nearly normal; it is only when this condition is accompanied by distension and obstruction that the analytical numbers are sub-normal. The composition of the juice appears therefore to be affected rather by the site than the character of the lesion. Analytical numbers higher than normal are characteristic of pyloric and duodenal ulcers. Attention is called to the value of pepsin estimations, and to certain low values of the pepsin, when the hydrochloric acid secreted is normal or even high. For the purpose of pepsin estimation, the Fuld-Levison edestin method was employed.   S. B. S.

The Entrance of Iodine into Diseased Tissues. H. GIDEON WELLS and O. F. HEDENBURG (*Proc. Amer. Soc Biol. Chem.*, 1912–13, xxxvi—xxxvii; *J. Biol. Chem.*, **14**).—Necrotic tissues, whether caused by tuberculosis or not, are more permeable to iodine, and therefore contain more than healthy tissues when iodine is given. W. D. H.

Pharmacological Investigations of Ammonium Chloride. RODOLFO MENEGUZZI (*Chem Zentr.*, 1913, i, 1046; from *Arch. Farmacol. sperim.*, 1912, **14**, 411—420).—The injection of ammonium chloride into the veins of a rabbit caused a retardation in the pulse-beats and an increase in the blood pressure, whilst the breathing was quickened at first, but suddenly ceased. A 1/40N-solution had a toxic action on the fresh gastrocnemius of a frog, but weaker solutions were without effect.   J. C. W.

Behaviour of Mercury [in the Organism]. ERNST SALKOWSKI (*Zeitsch. physiol. Chem.*, 1913, **84**, 67—68).—Polemical. Compare Buchtala (this vol., i, 318).   E. F. A.

The Injection of Salts of Radium. HENRI DOMINICI, (Mme.) SIMONE LABORDE, and ALBERT LABORDE (*Compt. rend.*, 1913, **156**, 1107—1109).—A study of the intravenous and intramuscular injection of soluble and insoluble salts of radium, which shows that they persist for a long time in the organism. In the case of the insoluble salts injected into the muscles the greater portion of the radium remains at the point of injection, whereas with the soluble salts it is diffused throughout the organism. The bony tissue retains an appreciable quantity of the radium injected as radium bromide, thus bringing radium into line with calcium and strontium in this respect.   W. G.

Thorium-X in Biology and Pathology.   J. PLESCH, LÁSZLÓ KAROZAG, and BRUNO KEETMAN (*Chem. Zentr.*, 1913, i, 318, from *Zeitsch. exper. Path. Ther.*, 1912, **12**, 1—84).—The behaviour and distribution of thorium-X in the animal organism are described. The measurements were made by estimating the α- or γ-radiation. About 80% is retained in the body, roughly two-thirds being stored in the bones, and most of the remainder in the liver.   The toxicity varies considerably for different animals, and a lethal dose for a man is calculated at 10,000 electrostatic units, whilst a therapeutic dose should not exceed 1000 units.   The symptoms accompanying the administration of thorium-X vary.   The respiration of healthy subjects is not affected, but in cases of cardiac weakness or pneumonia the blood pressure is reduced.   The preparation has a clinical application in metabolism, circulation and blood troubles, and in infectious diseases.   J. C. W.

Action of Thorium-X on the Circulation.   THEODOR A. MAASS and J. PLESCH (*Chem. Zentr.*, 1913, i, 318; from *Zeitsch. exper. Path. Ther.*, 1912, **12**, 85—94).—Experiments on the isolated heart of a frog show that, like radium emanation, thorium-X increases the diastolic relaxation of the heart.   J. C. W.

Experimental and Histological Investigation of the Action of Thorium-X on the Animal Organism.   A. PAPPENHEIM and J. PLESCH (*Chem. Zentr.*, 1913, i, 318; from *Zeitsch. exper. Path. Ther.*, 1912, **12**, 95—107).—The results of the action of thorium-X on the animal organism are to be referred to dilation of the blood vessels accompanied by bleeding and poisoning of the cells.   Thorium-X is also a poison to the leucocytes of the marrow of the bones and to the kidney and liver epithelia.   J. C. W.

Pharmacological Differences between *cis*- and *trans*-Isomerides.   HEINRICH DRESER (*Verh. Ges. deut. Naturforsch. Aerzte*, 1913, 122—123).—The following figures give before the / the lethal dose, and after the / the dose which is no longer lethal, in the case of frogs (F) and white mice (M).   The doses were injected under the skin, and are given in percentage-weights of the animal used.   Atropic acid, F, 0·45/0·40; M, 0·0054/0·0022.   Ordinary cinnamic acid, F, 0·30/0·25; M, 0·19/0·166.   *allo*Cinnamic acid, F, 0·46/0·42; M, 0·2/0·175.   *trans-o*-Coumaric acid, F, 0·45/0·40; M, 0·30/0·278.   *cis*Coumarinic acid, F, 0·084/0·0745; M, 0·01/0·0051.   *trans-o*-Methoxycinnamic acid, F, 0·20/0·15; M, 0·07/0·04.   *cis-o*-Methoxycinnamic acid, F, 0·7/0·5; M, 0·15/0·111.

The lethal doses are smaller for warm-blooded than for cold-blooded animals (compare atropic acid).   The *cis*-isomeride is less poisonous than the *trans*-isomeride; the exception shown by coumaric and coumarinic acids is due to the fact that the latter gives the very poisonous coumarin in the organism.   The introduction of phenolic hydroxyl into the ortho-position in *trans*-cinnamic acid decreases, whereas the methoxy-group increases, the toxicity.

The results show that no assumptions as to the pharmacological action of a substance can be based on chemical isomerism.

                                                                    T. S. P.

Pyruvic Acid Glycosuria. II. The Question of Sugar Formation from Pyruvic Acid. PAUL MAYER (*Biochem. Zeitsch.*, 1913, **49**, 486—501).—If pyruvic acid in suitable doses is administered to rabbits and dogs with total phloridzin diabetes, it causes an injury to the kidneys, which are rendered less permeable to nitrogenous substances and sugar. The administration in these cases results therefore in a diminution of both sugar and nitrogen in the urine. Even in cases where no injury to the kidneys could be ascertained, the administration of pyruvic acid led to no extra output of sugar. The experiments with animals with phloridzin diabetes offer, therefore, no solution of the problem as to whether pyruvic acid can be regarded as a sugar former in the body.

                                                                    S. B. S.

The Action of Methyl Alcohol on the Circulating Blood. SOICHIRO MIURA (*Biochem. Zeitsch.*, 1913, **49**, 144—151).—In two only out of five experiments (on four rabbits and one dog) did injection of methyl alcohol produce anæmia. There was observed a diminution of lymphocytes and an increase in the number of pseudo-eosinophile or neutrophile corpuscles and also hæmoglobinuria. The methyl alcohol appears to act toxically on the blood-forming apparatus.   S. B. S.

Caffeine Hyperglycæmia. THOR STENSTROM (*Biochem. Zeitsch.*, 1913, **49**, 225—231).—It has been assumed that caffeine preparations produce glycosuria by acting on the kidneys. If this is the case, then no hyperglycæmia should result. The author now shows, by experiments on rabbits, employing Bang's microchemical method of sugar estimation, that administration of caffeine derivatives leads to increase of sugar in the blood, which commences about an hour after administration, rises to a maximum and then falls. In two cases, after the maximum period there was a second very rapid rise and fall, which was accompanied by convulsions in the animals, which subsequently died. The conclusion is drawn that the glycosuria produced by caffeine preparations is not due to the action on the kidneys.   S. B. S.

The Behaviour of Dextrose-Resorcinol in the Animal Organism. LUCIANO PIGORINI (*Chem. Zentr.*, 1913, i, 319; from *Arch. Farmacol. sperim.*, 1912, **14**, 353—358).—The additive compound of dextrose and resorcinol (Fischer and Jennings, A., 1894, i, 397) is without harm to the frog or the guinea-pig, and is excreted unchanged, whereas resorcinol or mixtures of resorcinol and dextrose have a toxic action.   J. C. W.

The Destruction of α-Hydroxypropaldehyde and Methyl-glyoxal by Animal Organs. CARL NEUBERG (*Biochem. Zeitsch.*, 1913, **49**, 502—506).—It has been suggested that pyruvic

acid, as an intermediary product of sugar fermentation, can be formed by the Cannizzaro reaction from methylglyoxal. Equations are given showing that this substance can yield on hydrolysis (1) pyruvic acid and acetol, or (2) pyruvic acid and α-hydroxypropaldehyde, (3) pyruvic acid only. It was therefore of interest to investigate the behaviour of methylglyoxal and α-hydroxypropaldehyde when these substances are treated with various ferments from yeast or animal organs. Experiments show that with liver paste, both substances are destroyed, the former more rapidly than the latter. p-Nitrophenylhydrazine acetate was employed to detect their presence in the mixture, after the proteins had been precipitated by colloidal ferric hydroxide. More lactic acid was found in the incubation mixture than the organs alone would yield. The actual course of the reactions discussed has not, however, been yet entirely elucidated. S. B. S.

The Behaviour of Ferric Iodoparanucleate in the Organism. ERNST SALKOWSKI (*Biochem. Zeitsch.*, 1913, **49**, 152—164).—By the action of iodine on ferric paranucleate (triferrin), a product can be obtained which contains about 8% of organically combined iodine. It causes no toxic symptoms when administered to dogs and rabbits. On administration *per os*, the iodine, even in large doses, is completely absorbed into the system, whereas the iron is only partly absorbed. The iron content of the liver can be increased threefold after administration of iodotriferrin. No organically combined iodine could be detected in the body, after ingestion of the medicament, and the iodine appears to be excreted chiefly as alkali iodide, with a small quantity as an iodo-derivative of an aromatic acid. The iodine excretions last for three days after administration of the drug. S. B. S.

Enzyme Concerned with the Formation of Hydroxy-acids from Ketonic Aldehydes. HENRY D. DAKIN and HAROLD W. DUDLEY (*J. Biol. Chem.*, 1913, **14**, 155—157).—Phenylglyoxal administered to rabbits in doses of 1—1·5 grams per kilo. leads to the excretion of about half a gram of optically active *l*-mandelic acid and about 0·75 gram of hippuric acid. No phenylglyoxylic acid was detected. Aqueous extracts of various animal tissues contain an enzyme capable of converting phenylglyoxal into mandelic acid, the action of which is readily inhibited by heat.

By analogy, methylglyoxal should be converted into lactic acid, and an enzyme extract prepared from dog's liver is shown to effect this change.

Phenylglyoxal readily combines with histidine, arginine, ornithine, and lysine to give sparingly soluble yellow substances. E. F. A.

The Influence of Phloridzin on Dogs with Eck's Fistula. JOSHUA E SWEET and A. I. RINGER (*J. Biol. Chem.*, 1913, **14**, 135—138). —Phloridzin produces glycosuria in dogs with Eck's fistula exactly as in normal dogs. The power of gluconeogenesis is not lessened. W. D. H.

The Influence of Phloridzin on a Splenectomised Dog. JOSHUA H. AUSTIN and A. I. RINGER (*J. Biol. Chem.*, 1913, **14**, 139—140). —In dogs minus a spleen the effect of phloridzin exactly resembled those produced in normal animals.   W. D. H.

Lead Compounds in the Organism. ANTONIO RIVA (*Chem. Zentr.*, 1913, i, 1047—1048 ; from *Arch. Farmacol. sperim.*, 1912, **14**, 406—410).—The lead-poisoned liver of a dog was extracted by physiological salt solution, and the filtrate, containing the albumins, globulins, and nucleoproteins, was evaporated to dryness. Lead was only found in the globulin, apparently in combination, since it persisted after repeated dialysis. A globulin from horse serum showed a great affinity for lead.   J. C. W.

The Action of Dyes in Conjunction with Poisons and Medicaments. JOSEF SELLEI (*Biochem. Zeitsch.*, 1913, **49**, 466—478). —The mixture of dyes with poisons increases in many cases the toxicity of the latter, even although the dye is by itself practically inert. The dyes chiefly used were vitalneugelb, chrysoidin, methyl-orange, etc., which were combined with, amongst other substances, mercuric chloride, gold chloride, platinum chloride, and other metallic chlorides. Sodium vanadate mixed with a certain quantity of eosin is very toxic, but an increase of eosin in the mixture above a definite limit appears to diminish the toxicity. Other combinations of dyes with metallic poisons are less toxic than the metallic poisons alone. The influence of methylene-blue on the toxicity of copper salts was investigated. The most toxic of these, namely, cupric chloride, loses its toxic power most readily on mixture with the dye, whereas potassium cupric tartrate, which is the least toxic, acts in the presence of methylene-blue most toxically. The mixtures of dyes with the copper salts produce convulsions in the animals (guinea pigs); they also act as strong irritants at the place of injection. The author discusses the theory of the action of dyes.   S. B. S.

Influence of Poisons on the Isolated Heart of the Fish W. I. BERESIN (*Pflüger's Archiv*, 1913, **150**, 549—568).—The heart of the fish (hake) lends itself very well to physiological experimentation. Details are given of the method employed for isolating the heart, and the perfusion apparatus (a modification of Locke's) employed. If poisons are added to the perfusion fluid (Locke's fluid) their effects are readily observable. The poisons used were strophanthine, erythrophlein, caffeine, adrenaline, nicotine, pilocarpine, chloroform, ether, hydrocyanic acid, quinine, and veratrine. The effects are practically identical with those already known from work on the heart of the frog or the mammal; a few differences of detail were noted in one or two instances.   W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

The Phosphorus Compounds formed by Amylomyces Rouxii. R. GOUPIL (*Compt. rend*, 1913, **156**, 959—962).—*Amylomyces Rouxii* contains combined phosphorus in three states, two organic and one inorganic. The organic compounds are normal constituents of the living tissue, and their formation corresponds with the period of active growth. Of these two compounds one only is soluble in, and extracted by, ether, and is of a lecithin-like nature, whilst the second, which can be extracted by sodium hydroxide and reprecipitation by acids, possesses all the properties of a nucleic acid, and appears to be built up from the lecithin compound. The inorganic phosphates result from the degradation of the organic phosphorus compounds as the plant grows old.   W. G.

The Precipitation of Calcium Carbonate in the Sea by Marine Bacteria. G. HAROLD DREW (*J. Marine Biol. Assoc.*, 1913, **9**, 479—524).—The large, chalky, mud flats forming the Great Bahama Bank, and those near the Florida Keys, are now being precipitated by the action of *B. calcis* on the calcium salts dissolved in sea water. This or similar bacteria may have been an important factor in the formation of various chalk strata and oolitic rocks in addition to the part played by shells of foraminifera, etc. If this is correct, these strata must have been precipitated in shallow seas at tropical temperature. Bacterial denitrification is also far more rapid in tropical than in temperate waters; hence plankton and algæ growth is relatively scarce in the former. More extensive observations on the distribution of bacteria at different places and depths are, however, necessary.   W. D. H.

Alcoholic Fermentation of Lactic Acid. PIERRE MAZÉ (*Compt. rend.*, 1913, **156**, 1101—1104).—A study of the fermentation of lactic acid by a bacillus, capable of fermenting sugars and polyatomic alcohols, and comparable in its physiological properties to the *B. ethacetosuccinicus* of Frankland and Frew (T., 1892, **61**, 254). An examination of the results points to two parallel fermentation processes taking place on the lactic acid:

(1) $C_3H_6O_3 + O = CH_3 \cdot CO_2H + H \cdot CO_2H.$
(2) $C_3H_6O_3 = C_2H_5 \cdot OH + CO_2.$
The ratio of acetic acid to formic acid in the product is, however, as 5:1, the alcohol formed in (2) undergoing further oxidation, and this is confirmed by the value of the respiratory quotient. No pyruvic acid could be detected in any of the cultures at any stage.   W. G.

An Acid-producing Enzyme in Bacterium lactis acidi. E. G. HASTINGS and EDWIN B. HART (*Proc. Amer. Soc. Biol. Chem.*, 1912-13, xxxviii—xxxix; *J. Biol. Chem.*, **14**).—The enzyme in question acts on lactose, and the acid produced is probably lactic.   W. D. H.

q q 2

Employment of Lactic Acid and Lactic Acid Bacteria in the Pickling of Cucumbers. ALEXANDER KOSSOWICZ [with L. VON GRÖLLER] (*Chem. Zentr.*, 1913, i, 640; from *Zeitsch. Gärungsphysiol. Mykologie*, 1912, **2**, 78—80).—The presence of small quantities of lactic acid in cucumber sap or asparagine-sugar solutions prevents the development of bacteria of the *Mesentericus* group.   J. C. W.

A New Thermophilic Bacterium. ADOLF AMBROŽ (*Centr. Bakt. Par.*, 1913, ii, **37**, 3—16).—A sporogenous, facultative anaerobic organism, *Denitrobacterium thermophilum*, was obtained from soil and found to have the capacity of growing vigorously at 60—70°, and of decomposing nitrates with the liberation of free nitrogen. Analysis of cultures in nutrient bouillon, containing 0·5% potassium nitrate, showed that about 25% of the total nitrogen was lost during an incubation period of fourteen days at 60—65°. The gases were found to consist of nitrogen and oxides of nitrogen, the former being partly derived from the organic nitrogen compounds in the bouillon.   H. B. H.

The Mechanism of Alcoholic Fermentation. ALEXANDER VON LEBEDEV (*Ber.*, 1913, **46**, 850—851).—Polemical. A reply to Kostytschev (this vol., i, 323), stating that there is nothing essentially new in the latter's views.   D. F. T.

The Rate of Fermentation by Growing Yeast Cells. ARTHUR SLATOR (*Biochem. J.*, 1913, **7**, 197—203).—Various methods for estimating the rate of growth and fermentation are given, some of which are possible when the organism is growing on a solid medium. The rate of growth developing in wort-gelatin follows the logarithmic law.   W. D. H.

Chemical Composition and Formation of Enzymes. VIII. Simultaneous Variation in Amount of Invertase and Fermenting Enzyme in Living Yeast. HANS VON EULER and DAVID JOHANSSON (*Zeitsch. physiol. Chem.*, 1913, **84**, 97—108. Compare A., 1912, ii, 376, 970).—As the result of the previous treatment of the yeast in solutions containing mineral salts and sucrose or invert sugar there is an increase in the inverting power. This change cannot be regarded as an adaptation to environment, since the increase is the same whether the previous treatment is with sucrose or invert sugar. Neither is it due to a general increase in the vital activity of the cell, since the treatment materially lessens the fermentative activity. It is regarded as a special property due to causes as yet unknown.   E. F. A.

The Enzymes of Washed Zymin and Dried Yeast (Lebedev). I. Carboxylase. ARTHUR HARDEN (*Bio.-Chem. J.*, 1913, **7**, 214—217). —If zymin and Lebedev's dried yeast are washed free from co-enzyme they are incapable of fermenting dextrose, but they readily decompose pyruvic acid into carbon dioxide and acetaldehyde, provided that the acidity of the solution is kept low.
        W. D. H.

Action of Free Ammonia on Yeast. Comparison with Other Bases. THOMAS BOKORNY (*Chem. Zentr.*, 1913, i, 641—642; from *Allg. Brauer Hopfen Zeit*, 1912, 52, 2867—2869).—Seeds of cress, barley, wheat, hemp and vetch, and peas and scarlet runners were allowed to germinate in ammonia solutions from 0·1 to 0·01%. Only at the lower dilution did germination proceed, and even then, at a slower rate than in control experiments. Ammonia to the extent of 0·5% in a good culture solution prevented the growth of yeast, whilst potassium hydroxide in the same dilution had no effect. Yeast apparently combines with ammonia, for it was found that 12 grams of yeast with a dry weight of 3·6 grams contained 0·374 gram of the base. Hydroxylamine and phenyl-hydrazine hydrochlorides were poisonous to yeast in 0·1% solutions, whilst hydrazine hydrate in 0·002% and phenylhydrazine in 0·001% solutions entirely prevented any fungoid growth. J. C. W.

Microchemical Detection of Potassium in Yeast and Other Cells. THOMAS BOKORNY (*Chem. Zentr.*, 1913, i, 640—641; from *Allg. Brauer Hopfen Zeit.*, 1913, 52, 113—114).—In order to make the potassium cobaltinitrite precipitate more visible it is blackened by means of ammonium sulphide. It is possible to detect one part of potassium in 5000 at 8° by this method. Potassium could only be found in the cell sap of yeast, but the conclusion is not to be drawn that it is not present in the protoplasm or nucleus in the form of a potassium protein compound. Potassium is necessary for the development of yeast. J. C. W.

Action of Certain Metallic Salts on the Development of Yeast and the Germination of Barley. THOMAS BOKORNY (*Chem. Zentr.*, 1913, i, 641; from *Allg. Brauer Hopfen Zeit.*, 1912, 52, 1905—1906).—The reproduction of yeast was not influenced by the presence of even 4% of potassium dihydrogen phosphate in the culture solution, neither did the ash contain more phosphorus. Cæsium sulphate was found to be harmful to barley seedlings, even in the dilution of 0·05%, but 0·01% of that salt or 0·2% of rubidium sulphate proved to be beneficial, whilst potassium chloride in 0·05% solution did not accelerate germination, and in strong solutions was injurious. J. C. W.

Action of Uranium, Molybdenum, and Vanadium Salts on Yeast and Other Micro-organisms. THOMAS BOKORNY (*Chem. Zentr.*, 1913, i, 641; from *Allg. Brauer Hopfen Zeit.*, 1912, 52, 709—710. Compare A., 1912, ii, 1201).—During fermentations in presence of ammonium molybdate, the liquid acquired a blue colour, due to the action of that salt on hydrolysis products of sucrose, particularly on lævulose. J. C. W.

Influence of Different Substances on the Germination of Vegetable Seeds. I, II, and III. THOMAS BOKORNY (*Biochem. Zeitsch.*, 1913, 50, 1—48, 49—86, 87—118).—Potassium chloride is somewhat injurious to plants in 0·25% solutions, whilst the nitrate

is very injurious in 1% solutions, and may retard growth even in
0·1% solutions. Calcium nitrate (1%) is only slightly injurious, and
sodium nitrate somewhat more so; 0·1% solutions of both salts are
without injurious effects. Even 0·1% solutions of ammonium
nitrate retard germination. Whilst rubidium sulphate is only
slightly injurious in 0·5% solutions, cæsium and lithium sulphates
are injurious in 0·1 and 0·05% solutions respectively.

Germination is quickened by cæsium, lithium, and rubidium
sulphates in 0·01, 0·05, and 0·2% solutions respectively. The
germination of barley was promoted by 0·005% of carbon
disulphide; beans and lentils by 0·01% potassium chromate; cress
by 0·0005% mercuric chloride; barley and cress by 0·0025% and
0·005% copper sulphate respectively; cress by 0·005% of phenyl-
hydrazine; barley and cress by 0·0025% of aniline; barley by 0·01%
of hydroxylamine; and peas, lentils, and barley by 0·001% of
hydrofluoric acid.

It would seem that most poisons stimulate growth when diluted
to certain points. Since a slight increase in concentration causes
injury and a slightly increased dilution renders the substances
inactive, it is doubtful whether this property of poisons can have
any practical importance.   N. H. J. M.

Action of Manganese Dioxide and of Other Metallic Com-
pounds on the Germination of Seeds. UGO VARVARO (*Chem.
Zentr*, 1913, i, 546—547; from *Staz. sperim. agrar. ital.*, 1912, 45,
917—929).—The oxides of manganese, iron, uranium, cerium,
copper, zinc, aluminium, cadmium, and mercury hinder the germina-
tion of beans, and are poisonous, even in small doses, to horse
beans. The oxides of zinc, lead, copper, cadmium, aluminium, and
uranium are stimulants to maize.   J. C. W.

Formation of Pentosans in the Germination of Seeds.
LUIGI BERNARDINI and F. GALLUCCIO (*Chem. Zentr.*, 1913, i, 179; from
Staz. sperim. agrar., ital., 1912, 45, 874—884).—The pentosans
developed by seeds germinating in the dark and in the light have
been estimated by Tollens's and Krüger's phloroglucinol method, and
the cellulose by König's glycerol-sulphuric acid method. The
results show that the production of pentosans is slow in the dark,
but rapid in the light, whilst the cellulose content rises at first in
the dark, only to fall off rapidly as germination proceeds, but
increases steadily in the light.   J. C. W.

Respiration of Plants as Hydrolytic Oxidation. VLADIMIR
I. PALLADIN (*Ber. deut. botan. Ges.*, 1913, 31, 80—82).—Alkaline
solutions of the respiration chromogens absorb atmospheric oxygen
vigorously with production of brownish-red pigments. During
alcoholic fermentation, hence in the first anaerobic stage of respira-
tion, substances are formed which readily give up their hydrogen
to the respiration pigment, by which it is oxidised to water by means
of atmospheric oxygen.

The respiration chromogens, like the leuco-compounds, give up

their hydrogen to the absorbed oxygen, producing a pigment and water. The oxygen absorbed during respiration is employed, therefore, as previously shown, in removing hydrogen from the plants.

The hydrogen liberated after the hydrolytic oxidation of dextrose, which in higher plants is oxidised to water and in yeast is eliminated as ethyl alcohol, is given up by anaerobic bacteria to the surrounding gaseous medium.   N. H. J. M.

Causes of Growth of Plants. G. A. BOROVIKOV (*Biochem. Zeitsch*, 1913, 50, 119—128. Compare this vol , i, 324) —Salts which are readily hydrolysed are favourable to growth owing to the presence of acids, and consequently of hydrogen ions. The weaker the base the more easily is it hydrolysed, and the stronger the action of the salt. In solutions of salts of strong organic bases, growth is not quickened because hydrolysis is less, and because such bases have a greater retarding effect than weak bases, such as caffeine, carbamide, and glycine. The quickening or retarding of growth seems to be due to unequal degrees of hydration of the plasma colloids. The conditions which are favourable to the ionisation of the protein also bring about greater hydration of the plasma colloids. Acids are favourable to plants, whilst metals and bases diminish the protein ionisation by neutralising the protein.   N. H. J. M.

Formaldehyde and Plant Syntheses. HERMANN DECKER (*Annalen*, 1913, 396, 336).—The hypothesis of the action of formaldehyde as a methylating agent in the formation of plant substances, advanced by Decker and Becker (this vol., i, 291), was suggested by Pictet eight years ago.   C. S.

Plants which Require Sodium. WINTHROP J. V. OSTERHOUT (*Bot. Gaz.*, 1912, 54, 532—536).—Sodium was found to be as necessary for the marine plants employed as for animals, and its replacement in sea-water by ammonium, potassium, cæsium, lithium, magnesium, calcium, and strontium is injurious. The best substitutes are the elements which predominate in sea water, magnesium, calcium, and potassium.

The behaviour of various species indicates that each salt has a specific action.   N. H. J. M.

Antagonistic Action of Chemical Substances on Fungi. Chemical Preservation. THOMAS BOKORNY (*Cent. Bakt. Par.*, 1913, ii, 37, 168—267).—Numerous experiments are described on the action of various inorganic and organic substances on fungi, yeasts, etc. The results are summarised in tables.   N. H. J. M.

Assimilation of Nitrites by Moulds ALEXANDER KOSSOWICZ (*Chem. Zentr.*, 1913, i. 640 ; from *Zeitsch. Gärungsphysiol. Mykologie*, 1912, 2, 55—58).—Ten moulds have been found to subsist with nitrites as their source of nitrogen, and since in only two cases could ammonia be detected, the conclusion is drawn that the

nitrite ion is assimilated directly, without reduction. In good culture media, moderate concentrations of nitrites are not poisonous to moulds. J. C. W.

Decomposition of Carbamide, Uric Acid, Hippuric Acid, and Glycine by Moulds. II. ALEXANDER KOSSOWICZ (*Chem. Zentr.*, 1913, i, 640; from *Zeitsch. Gärungsphysiol. Mykologie*, 1912, 2, 51—55).—Several of the well-known moulds are able to make glycine or hippuric acid their sole source of nitrogen in presence of mannitol or dextrose, some of them producing ammonia. Certain moulds can depend on uric acid, hippuric acid, or glycine for their combined source of carbon and nitrogen. J. C. W.

Chemistry of the Higher Fungi. IX. Galls Produced by Exobasidium Vaccinii, Woron, on Rhododendron ferrugineum, L JULIUS ZELLNER (*Monatsh.*, 1913, 34, 311—319. Compare A., 1912, ii, 196).—The galls and the leaves on which they are found have been examined, and shown to contain the same constituents, the former containing a larger proportion of water-soluble substances, except tannin, and a smaller proportion of matter insoluble in water, than the leaves. On this and other grounds, it is suggested that the formation of galls on leaves is similar in character to the production and ripening of fruits.

The galls and the leaves were extracted in turn with light petroleum, ether, 95% alcohol and water, and the composition of these extracts was as follows: The galls yielded 1·71% to light petroleum; the product was a thick, semi-crystalline oil, having acid number 93·4, saponification number 165·1, and containing 12·5% of unsaponification matter, composed of (*a*) a *substance*, m. p. 129—130°, $[\alpha]_D^{18} - 29\cdot4°$, crystallising in colourless needles, and (*b*) a *substance*, m. p. above 280° (decomp.), much less soluble than the foregoing; both these products are phytosterols. The fatty acids of the oil are semi-solid. The leaves yielded 9·2% to light petroleum; the extract had acid number 60, saponification number 150, and contained the same two phytosterols as the gall extract, and also much resin and terpenes.

The ether extract of the galls amounted to 2·68%, and consisted of tannin and resin. The leaves yielded 8·34% to ether, and this extract also consisted of tannin and resin, the latter being somewhat different from that in the galls.

The alcohol extract of the galls amounted to 39·1%, and consisted of phlobaphen, dextrose, lævulose, tannin, and organic acids. The leaves yielded 32·6% to alcohol, and this extract consisted chiefly of tannin with some phlobaphen and a small amount of sugar.

The aqueous extract of the galls amounted to 13 32%; it contained some tannin, but was mostly gummy carbohydrate; no starch was present. The leaves gave only 1·7% of aqueous extract of similar composition to the foregoing, but containing some starch.

All the foregoing yields are expressed as percentages of the original material dried at 100°. T. A. H.

Chemistry of the Higher Fungi. X. JULIUS ZELLNER (*Monatsh.*, 1913, **34**, 321—336).—In this portion four fungi are dealt with, the method of investigation being the same as that described in the preceding abstract.

Armillaria mellea, Vahl.—The light petroleum extract was a semi-crystalline, thick, brown oil, having acid number 89·1, saponification number 179·6, iodine number 94·2, and containing notable amounts of lecithin and 4·5% of unsaponifiable matter, the latter consisting of a yellow resin and some ergosterol. The fatty acids were mostly liquid, but yielded when kept a mixture of crystalline acids, m. p. 62°, and acid number 210°. The ether extract contained some amorphous matter and ergosterol, m. p. 155°, $[a]_D - 114·8°$ in chloroform, which gave an acetyl derivative, m. p. 169°. No cerebrin was found. The alcoholic extract deposited after a time mannitol, m. p. 169—170° (possibly contaminated with mycose), dextrose, choline ?, and matter precipitated by lead acetate.

Lactarius piperatus, L. (compare Thörner, A., 1880, 44; Bissinger, A., 1884, 480; Chodat and Chuit, A., 1890, 80; Gérard, A., 1891, 606; and Bougault and Charaux, A., 1912, ii, 289).—The light petroleum extract amounted to 5·9%, and was a solid, yellow fat, having acid number 121·3 and saponification number 200·2. The unsaponifiable matter was separated into (1) a substance, m. p. 146—150°, probably a mixture of ergosterols; (2) a yellow resin; and (3) a sparingly soluble substance, m. p. 150° (approx. decomp.). This extract also contained lecithin. The fatty acids included some liquid acids, but the principal constituent was stearic acid, which was isolated in quantity (*loc. cit.*). The ether extract amounted to 1·2%, and consisted of yellow resin. The alcoholic extract contained mannitol (possibly contaminated with inositol), dextrose, and choline (compare Bourquelot, A., 1890, 103).

Pholiota squarrosa, Müll.—The light petroleum extract (3·8%) was a semi-solid, yellowish-brown fat, having acid number 51·8, saponification number 168·3, containing lecithin and 12·9% of unsaponifiable matter. From the latter a resin and a mixture of ergosterols, m. p. 159 (approx.), crystallising in colourless leaflets, were isolated. The ether extract resembled the foregoing in composition. The alcoholic extract contained mannitol, mycose, dextrose, choline, phlobaphen, and indefinite amorphous matter soluble in alcohol, but not in water.

Polyporus betulinus.—The light petroleum extract amounted to 3·5%, and had acid number 96·3, saponification number 155·0, iodine number 98·6, and contained 17·8% of unsaponifiable matter composed of a mixture of ergosterols, m. p. 139—144°, $[a]_D - 97·6°$, crystallising in needles or leaflets, cerebrin, resin, and gum. The ether extract was resinous, and contained a *substance*, $C_{31}H_{50}O_5$, m. p. 250° (approx. decomp.), which is probably an alcohol and is named *polyporol*. The alcoholic extract contained phlobaphen, mannitol, dextrose, traces of choline, and indefinite substances precipitated by lead acetate and other salts. The aqueous extract contained potassium phosphate and a carbohydrate, giving a pale

greyish-blue coloration with iodine, and readily hydrolysed by dilute hydrochloric acid. Winterstein's para*iso*dextran (A., 1895, i, 323) could not be obtained.   T. A. H.

Extraction of the Colouring Matter from the Cherry and Investigations of its Properties GIULIO MASONI (*Chem. Zentr.*, 1913, i, 546; from *Staz. sperim. agrar. ital.*, 1912, 45, 885—907).— The pigment may be extracted from fresh or dried cherries by means of water or alcohol with the help of a little tartaric or hydrochloric acid. The aqueous extract may be cleared by gelatin, and is violet-red and not very stable, whereas the alcoholic extract is clear, pure red in colour, and remains unaffected by heat or light. The dye may be applied to wool or food-stuffs. Its presence in wine may be detected, after clearing the liquid with lead acetate, by the addition of alum, when a violet coloration is produced, pure wines remaining colourless.   J. C. W.

Chemical Examination of Euphorbia pilulifera. FREDERICK B. POWER and HENRY BROWNING, jun. (*Pharm. J.*, 1913, [iv], 36, 506—510). —A complete chemical examination of the entire plant, collected in Fiji, has been made. None of the definite constituents isolated has any specific physiological action, so that such therapeutical value as the plant possesses cannot depend on any single definite substance. An alcoholic extract of the plant was steam-distilled, and yielded (1) a volatile oil, b. p. 235—260°, giving the colour reaction of furfuraldehyde; (2) a portion soluble in water; (3) a resinous portion, insoluble in water; the two latter portions of the extract were then examined by methods which are described in detail, and gave the following products:

Portion Soluble in Water.—This yielded gallic acid, quercetin, a small amount of jambulol (see also below), and a phenolic *substance*, $C_{25}H_{18}O_5$, which crystallised in microscopic clusters of needles, and decomposed, but did not melt, at 340°. There was also present a lævorotatory sugar, which yielded *d*-phenylglucosazone, some amorphous glucosidic matter, traces of an alkaloidal substance, together with indefinite oily and extractive matters.

Portion Insoluble in Water.—This yielded melissic acid, ceryl alcohol, triacontane, a *phytosterol*, m. p. 132—133°, crystallising in flattened needles, and giving an *acetyl* derivative, m. p. 122—123°; a *phytosterolin*, $C_{33}H_{56}O_6$(?), m. p. 297° (decomp.), crystallising in colourless needles, and yielding an *acetyl* derivative, m. p. 161—162°, crystallising in flattened needles; jambulol (T., 1911, 99, 962, and A., 1912, ii, 480), and a mixture of palmitic, oleic, and linoleic acids. In addition, a monohydric alcohol, *euphosterol*, $C_{25}H_{39}\cdot OH$, m. p. 274—275°, was obtained. This crystallises from petroleum in needles, gives the colour reaction characteristic of this class of substances (T., 1909, 95, 739; 1912, 101, 2425), and is optically inactive. It yields an *acetyl* derivative, m. p. 295—297°, $[\alpha]_D + 8\cdot2°$ in chloroform, and this on bromination in cold chloroform gives *bromoacetyleuphosterol*, m. p. 183—186°, crystallising in small needles from a mixture of alcohol and ethyl acetate.

Euphosterol is probably accompanied by other alcohols of the same series, since in recrystallising the acetyl derivative two other fractions, m. p. 205—210° and m. p. 230—260°, were obtained.

T. A. H.

Causes of the Natural Changes in the Latex of Hevea Brasiliensis. G. STAFFORD WHITBY (*Z-itsch. Chem. Ind. Kolloide*, 1913, 12, 147—157).—Experiments are described which have been made in order to ascertain the nature of the changes which are involved in the coagulation of the latex of *Hevea Brasiliensis* when this is left in contact with the air. The observations indicate that coagulation is brought about by an enzyme (probably a protease). Anærobic decomposition occurs in those portions which are out of contact with the air, and evidence has also been obtained which indicates the presence of an oxydase, to which the name, *hevease*, is applied.

A fourth factor in the coagulation process consists in ærobic decomposition, which occurs in the later stages, and gives rise to an alkaline mucus which causes the latex to become milky. The relative importance of these four independent processes depends very largely on the conditions under which coagulation of the latex occurs.

H. M. D.

Herbage Studies II. Variation in Lotus Corniculatus and Trifolium repens (Cyanophoric Plants). HENRY E. ARMSTRONG, E. FRANKLAND ARMSTRONG, and EDWARD HORTON (*Proc. Roy. Soc.*, 1913, *B*, 86, 262—269).—It is established that in addition to the common widely distributed cyanophoric form of *Lotus corniculatus*, a botanically indistinguishable form exists, in which the power of producing the cyanophoric glucoside is all but suppressed. *Lotus major* is uniformly cyanophoric. The normal form of *L. corniculatus* contains both glucoside and the correlated enzyme; a second form is rich in enzyme, but contains mere traces of the glucoside, whilst in the third form the amount of both glucoside and enzyme is very small.

The conclusion is drawn that the above differences are due to the presence or absence of definite factors rather than the consequence of the operation of special conditions of environment.

Whereas cultivated white clover (*Trifolium repens*) is without cyanide, wild white clover always contains a cyanophoric glucoside.

The determination of the enzymic activity of a number of specimens of *Trifolium repens* showed that all were moderately active towards salicin, but that the cultivated variety alone was practically without action on linamarin and prunasin.

The bearing of the chemical peculiarities of the two types of clover on their value as food materials is discussed.   E. F. A.

Chemistry of Peat Moss (Sphagna). JOSEF IBELE (*Ber. deut. bot. Ges.*, 1913, 31, 74—77).—When *Sphagnum papillosum* is oxidised with hydrogen peroxide a substance soluble in sodium hydroxide

solution is obtained, which becomes insoluble when precipitated with acid and dried. Formic acid and ammonia are also formed.

Sphagnum dissolves almost completely in hydrochloric acid containing antimony trichloride. Ammonia is liberated, but no methylamine could be detected.   N. H. J. M.

Glucosides and Oils of the Primrose. A. GORIS, M. MASCRÉ, and CH VISCHNIAC (*Chem. Zentr.*, 1913, i, 310—311; from *Bull. Sci. Pharmacol.*, 1912, 19, 577—598, 648—670; *Wiss. ind. Ber. Roure-Bertrand fils*, 1912, 6, 3—73 Compare A., 1910, ii, 63).—The crude glucosides which form about one part per thousand of the roots of *Primula officinalis* may be separated by fractionation from a mixture of ethyl acetate and alcohol. Primverin (I), $C_{20}H_{28}O_{13}$, m. p. 206° (corr.), $[\alpha]_D -71°53'$, yields on hydrolysis with dilute acids, *methyl β-methoxyresorcylate*, $C_9H_{10}O_4$, m. p. 49°, which develops a violet-red colour with ferric chloride, and two molecular proportions of monoses. The enzyme primverase, however, produces the biose, *primverose*, $C_{11}H_{20}O_{10}$, m. p. 209—210°, which exhibits multirotation; $[\alpha]_D +23°1'$, $-2°3'$ after twenty-four hours (1·846 grams in 75 c.c. H_2O), $+23°11'$, $-3°17'$ after twenty-four hours (1·35 grams in 26 c.c. of water). It reduces Fehling's solution (0·0673 gram = 77 mg. Cu), forms an *osazone* in light yellow needles, m. p. 204—207°, and contains a pentose, apparently in combination with a hexose.

$$CO_2Me$$
$$\cdot O \cdot C_{11}H_{19}O_9$$

$$OMe$$
(I.)
$$CO_2Me$$
$$OMe \quad O \cdot C_{11}H_{19}O_9$$
(II.)

Primulaverin, $C_{20}H_{28}O_{13},2H_2O$, m. p. 163° (corr.), $[\alpha]_D -66°65'$, yields on hydrolysis the same sugars and *methyl m-methoxysalicylate*, mixed with methyl β-methoxyresorcylate. It has not yet been obtained pure, but the true primulaverin would have the formula II.

The ethereal oils of the primrose root contain the above esters, whilst the oil from the flowers contains, in addition, over 10% of an unhydrolysable substance.   J. C. W.

Willow Bark. I. GEORGEI GEORGEVITSCH POVARNIN and A. BABABANOV (*J. Russ. Phys. Chem. Soc.*, 1913, 45, 267—271).—The authors have examined the barks of a number of willows, including hybrids, with the object of classifying them according to their chemical reactions. Tannides of two distinct types occur in the barks (see following abstract).   T. H. P.

Willow Bark. II. GEORGEI G. POVARNIN and N. SHURAVLEV (*J. Russ. Phys. Chem. Soc.*, 1913, 45, 271—283. Compare preceding abstract).—The bark of the hybrid willow, *Salix alba × S. viminalis*, contains, in addition to phlobaphens, two tannides which are char-

acterised by their reactions with ferric chloride and with ammoniacal copper sulphate. The tannide of *S. alba* is a tannoside, and may be separated from that of *S. viminalis,* which contains free sugar, by its different solubility in a mixture of methyl alcohol and ether. The former gives anhydro- and oxy-phlobaphens, and it contains protocatechuic acid, whilst the tannide of *S. viminalis* contains pyrogallol, but the principal decomposition products are phlobaphen and sugar.   T. H. P.

Manuring of Cultivated Plants by means of Carbon Dioxide. ADOLPH HANSEN (*Chem. Zentr.*, 1912, ii, 2135; from *Naturw. Rundsch.*, 1912, **27**, 547—550).—It was noticed that the vegetation in the neighbourhood of a natural carbonic acid spring was particularly fine, and the administration of carbon dioxide to cultivated plants is found to increase the dry weight considerably. It is suggested that the gas is loosely combined with the chlorophyll in the same way as oxygen is united to the pigment of the blood.
                                                                J. C. W.

Importance of the Potassium in Felspar for Plants. EDWIN BLANCK (*J. Landw.*, 1913, **61**, 1—10. Compare *ibid.*, 1912, **60**, 97).—Pot experiments in which oats were manured with various potassium minerals. Previous results, indicating that the tubes are more suitable as sources of potassium for plants, are confirmed.
Plagioclase gave much better results than microlin and orthoclase, which were almost without effect.   N. H. J. M.

History of Maize Sugar. PH. DE VILMORIN and FERDINAND LEVALLOIS (*Bull. Soc. chim.*, 1913, [iv], **13**, 294—301) —The authors give an extensive review of the efforts which have been made to extract a crystallisable sugar from maize on the industrial scale, special reference being made to the work of Pallas and to the recent investigations of Stewart and of Heckel (*Compt. rend.*, 1912, **155**, 686).
A series of experiments have been made on maize from Verrières and from Antibes, the conditions, however, being rather unfavourable. In these circumstances, the juice from maize from which the ears had been removed during growth was found to contain 10% of sucrose, whilst a greater proportion could be extracted from sugar maize. From the industrial point of view, the extreme rapidity, both of formation and of decomposition of sugar in maize, constitutes a serious difficulty, which, however, could possibly be obviated to some extent by the systematic employment of different varieties of maize.   H. W.

Respiration and Metabolism in Ruminants. NATHAN ZUNTZ, RICHARD VON DER HEIDE, KLEIN, I. VON MARKOFF, FÜRST VON DSCHANDIERI, and DJADKOW (*Landw. Versuchs-Stat.*, 1913, **79**-**80**, 781—814).—The utilisation of foods by cattle varies according to the mechanical condition of the mixture, and the same food will give different results when given in conjunction with other foods. An experiment is described in which potatoes were compared with

the corresponding amount of potato slump to which starch was added to replace that which had been lost; whilst malt and yeast were added to the potatoes. Although the two foods had practically the same composition, the results with starch were essentially different from those with potatoes. When starch is given in conjunction with hay, the crude fibre, protein, and fat are digested in diminished amounts. In the case of the non-nitrogenous extract the amount in the fæces was diminished by the starch. This does not, however, indicate better resorption, as there is no doubt that the extractive substances were lost by fermentation. The comparison of food and fæces is misleading in the case of ruminants.

It is desirable in feeding experiments to estimate the amount of oxygen utilised as well as the amounts of respired nitrogen and carbon dioxide. A method for estimating the oxygen is described.

The various estimations in respiration experiments should be made at short intervals.

Methods for investigating the fermentation processes of the rumen are discussed.   N. H. J. M.

Employment of Dialysis in the Estimation of the Oxidising Power of Soils. JOSEF KÖNIG, JULIUS HASENBAUMER, and K. GLENK (*Landw. Versuchs-Stat*, 1913, **79–80**, 491—539).—Several soils were subjected to dialysis, and the amounts of organic matter, calcium, magnesium, potassium, phosphoric acid, and sulphuric acid in the solutions estimated. It was found that soils which were heated at 150° yielded considerably more soluble matter than soils which had not been heated; similar results, but less marked, were obtained with soils dried, under reduced pressure, at 95—98°. Clearer indications of the changes which soils undergo when heated, and even when air-dried, were obtained by estimating the electrolytic conductivity. The results indicate that in the ordinary drying of soils the colloidal state is in part destroyed.

The amounts of carbon dioxide produced in six different soils, and in the same soils with small amounts of dextrose and urea respectively, were estimated daily for three weeks; and at the end of the experiment the amounts of ammonia and nitrates and the numbers of bacteria were estimated (compare Hutchinson and Marr, A., 1911, ii, 430). As regards nitrification, the urea was almost completely nitrified in the loamy soil, whilst the clay soil showed very slight nitrification. Addition of dextrose considerably increased the number of bacteria in all the soils. Electrolytic conductivity was increased by urea and diminished by dextrose.

The results of pot experiments with oats showed that heating the soil at 95—98° in a vacuum increased both the total growth and the mineral constituents. Addition of dextrose and gum arabic to loamy sand and loam diminished the yield of grain and straw.

                                                    N. H. J. M.

Colloidal Substances in Soil Solutions. Production of Soda in Soils. Alkali and Salt Soils. K. K. GEDROIZ (*Bied. Zentr.*, 1913, **42**, 76—79; from *J. exper. Landw.*, 1912, **13**, 421).— The amount of colloids in soil extracts (except alkali soil extracts)

was found to vary from 0·0018 to 0·0200%, and in Russian arable soils from 0·0058 to 0·0147%. The dry matter dissolved by water amounted to 0·0385 to 0·0591%. The coagulation of such small amounts of colloidal substances can have very little effect on the physical properties of the soils; and the changes brought about by frost, electrolytes, and liming, etc., are attributed to their influence on substances mechanically suspended in the soils, especially the gels.

In the case of alkali soils the total colloids, mineral and organic, varied from 0·0990 to 0·4494%; in such soils coagulation of the colloids may influence the physical properties of the soil.

In typical alkali soils, nearly free from chlorides and sulphates, the amount of soda in successive extracts decreases much more slowly than would be the case if only pre-existing soda were dissolved. In alkali soils containing much sodium chloride, but little sulphate, alkalinity begins only after some of the chloride is washed out.

A loamy, black soil, treated with sodium chloride and calcium carbonate, failed to yield appreciable amounts of soda, and only small amounts were produced by treatment with sodium sulphate and calcium carbonate. Under the combined influence of sodium chloride and sulphate, alkaline, dark-coloured solutions were obtained after the removal of most of the chloride and sulphate; in presence of calcium carbonate the soil yielded soda. The conclusion is drawn that the soda is produced from zeolites. The production of soda is hindered by excessive amounts of sodium chloride and sulphate.   N. H. J. M.

The Fertilising Action of Sulphur. A. DEMOLON (*Compt. rend.*, 1913, **156**, 725—728).—Further experiments with sulphur (compare A., 1912, ii, 382) show that it can act as a useful addition to farmyard manure as a fertiliser, but that its action diminishes and vanishes in the presence of a large amount of organic and mineral fertilisers. Potatoes benefit most by the addition of sulphur. On light lands it has an injurious effect on cereals. Addition of sulphur in amount equal to the nitrogen supplied has given the same results as a complete mineral fertiliser. The fertilising action of the sulphur is due (*a*) to its action on the soil bacteria, (*b*) to its progressive transformation into sulphuric acid.   W. G.

[Manurial] Action of Different Forms of Nitrogen. W. SCHNEIDEWIND (*Bied. Zentr.*, 1913, **42**, 101—110; from *Arb. deut. Landw.-ges.*, Heft. 217).—Pot and field experiments on the action of sodium and calcium nitrates, calcium nitrite, ammonium salts, calcium cyanamide, and urine. On the whole the best results were obtained with sodium and calcium nitrates. Ammonium salts were not regular in their action; in one case, both on dry and wet soils, ammonium salts gave better results than nitrate. Both with oats and potatoes, nitrates and ammonium salts gave the same results. Calcium cyanamide acted most favourably when applied in the autumn for winter cereals. Urine was unsatisfactory both on light and loamy soils. The effect of calcium nitrite was variable.

The application of large amounts of manure to light soils in the autumn is useless; ammonium salts and calcium cyanamide may, however, be applied to soils of better quality.   N. H. J. M.

Influence of Ammonium Sulphate on the Phosphate Manuring of Oats. EILHARD A. MITSCHERLICH and W. SIMMERMACHER (*Landw. Versuchs-Stat.*, 1913, 79–80, 71—96).—Addition of ammonium, sodium, and magnesium sulphates considerably increased the solubility of the phosphoric acid of di- and tri-calcium phosphates, whilst in presence of calcium phosphate the solubility is diminished.

The results of vegetation experiments, in which oats were manured with di- and tri-calcium phosphates, showed that the addition of small amounts of ammonium sulphate increased the amounts of phosphoric acid assimilated even in presence of considerable amounts of soluble salts which would be acting in the same direction.

In the case of superphosphate and basic slag, addition of ammonium sulphate was without effect on the assimilation of the phosphoric acid by oats.   N. H. J. M.

Manuring with Sodium Salts. BERNHARD SCHULZE (*Landw. Versuchs-Stat.*, 1913, 79–80, 431—448). — Sodium is utilised by plants, and may take the place of potassium to a certain extent. The sodium of sodium chloride is taken up by plants with great rapidity; and, as it is not absorbed by soils to the same extent as potassium, its manurial action lasts longer if not washed out of the soil.

Whilst potassium salts decompose sodium zeolites in the soil, sodium salts have a very slight action, if any at all, on potassium zeolites.   N. H. J. M.

Lime Rich in Silica as Manure. HEINRICH IMMENDORFF (*Landw. Versuchs-Stat.*, 1913, 79–80, 891—901).—Different soils were rubbed in a mortar with lime and water, and then put on to glass plates to dry in order to ascertain whether any hardening of the soil takes place owing to the presence of silica. The limes employed contained from 0·03 to 19·51% of soluble silica (Portland cement). The same soils were treated with water alone for comparison.

The results showed that no hardening of the soil takes place when lime containing large amounts of soluble silica are employed. Hydrated silica may itself have a favourable effect on the soil by increasing its absorptive power.   N. H. J. M.

Organic Chemistry.

Composition of Mineral Oils of High Boiling Point. I. The Viscous Components of Mineral Oils of High Boiling Point. JULIUS MARCUSSON (*Chem. Zeit.*, 1913, **37**, 533—534).—Previous .investigations (*ibid.*, 1911, **35**, 729) have shown that the more viscous portion of mineral oils (naphthenes, polynaphthenes, paraffins, and olefines) is that which does not react with formaldehyde and sulphuric acid, whilst the reacting portion (benzene derivatives, unsaturated naphthenes, and terpenes) is comparatively mobile. Paraffins have small viscosity, whilst that of naphthenes is greater than that of paraffins of the same molecular weight. The viscosity of mineral oils cannot therefore be attributed to the presence of paraffins. This is confirmed by the fact that the viscosity of lubricating oils can be raised by removal of solid paraffins and lowered by their addition. Olefines are present in too small amount to exert a distinct effect on the viscosity, so that the diminution in viscosity effected by treating oils with fuming nitric acid at $-10°$ must be attributed to the destruction of polynaphthenes. The viscosity must therefore be due to the presence of naphthenes and polynaphthenes. The former are mainly present in the portions distilling below $300°$, so that in oils of high b. p. and high viscosity, the chief saturated hydrocarbons are polynaphthenes. This is confirmed by analysis of a heavy Russian machine oil, which, before purification, contained $C = 85.79\%$ and $H = 12.78\%$, whilst after treatment with formaldehyde and sulphuric acid, the figures obtained were $C = 85.41\%$, $H = 13.07\%$, which correspond with the results to be expected from a mixture of condensed naphthenes. Further confirmation is found in the high molecular weight of machine oils, which ranges from 300 to 400 with a mean value of about 350, corresponding with compounds containing twenty-five atoms of carbon in the molecule.

Highly viscous oxygen compounds are present in nearly all machine oils, but, generally, in such small amount that their effect is inconsiderable.

The present communication deals only with machine oils. Cylinder oils are under investigation. H. W.

Composition of Mineral Oils of High Boiling Point. II. Components of Liquid Paraffin and their Behaviour towards Aluminium Chloride. JULIUS MARCUSSON and C. VIELITZ (*Chem. Zeit.*, 1913, **37**, 550—553).—The so-called liquid paraffin is generally regarded as a mixture of liquid hydrocarbons of the paraffin series. This view, however, appears improbable, since the substance is usually obtained from Russian oils which are comparatively poor in such hydrocarbons.

Two specimens of liquid paraffin were employed, having D_4^{20} 0.8827, 0.8858, n^{20} 1.4797, 1.4799, specific viscosity at $20°$, 23.0, 29.9,

$[\alpha]_D$ +2·13, 2·35, respectively. The density and refractive index indicate that hydrocarbons of the paraffin series cannot be the main components of the mixture, whilst ultimate analysis points to the presence of polynaphthenes.

In order to decide whether the optical activity is attributable to *iso*paraffins or polynaphthenes, a specimen of liquid paraffin was fractionated under greatly reduced pressure. Density, viscosity, refractive index, and optical activity were found to increase with increasing b. p. of the fraction. Since the fraction, b. p. 255—277°/ 4 mm., was completely liquid and only yielded a trace of precipitate when cooled with alcohol–ether to −20°, it appears improbable that *iso*paraffins can be the cause of activity. This is confirmed by the results of an ultimate analysis, and further by the fact that optical activity is not lost when liquid paraffin is subjected to energetic treatment with fuming nitric acid. Activity must therefore be due to the presence of polynaphthenes, which is in accord with the observation of Bushong and Humphrey (*Chem. Zeit.*, 1912, **36**, 1139) that optically active naphthenic acids are present in mineral oil.

The optically active constituents of liquid paraffin are stable towards fuming sulphuric or fuming nitric acid, but are readily inactivated by aluminium chloride. When a solution of liquid paraffin in carbon disulphide was heated on the water-bath during three hours with aluminium chloride and the residue left after removal of the solvent was extracted with light petroleum, a colourless oil was obtained, which possessed feeble optical activity and considerably lower density, refractive index, and viscosity than the original material. From that portion of the reaction product which was insoluble in light petroleum, a viscous, brown substance was obtained, solutions of which were too deeply coloured to permit polarimetric observation. In the absence of any solvent, similar inactivation was observed. With light petroleum as solvent, however, the recovered oil had nearly the same properties as the original specimen. This difference is probably attributable to the fact that the yellowish-white additive product formed from liquid paraffin and aluminium chloride is practically insoluble in light petroleum, whilst it is appreciably soluble in carbon disulphide and also in liquid paraffin. In the first case, therefore, the liquid paraffin becomes practically protected from further action of aluminium chloride.

Finally, a series of experiments has been performed on the action of aluminium chloride on different optically active substances dissolved in carbon disulphide. Camphor and castor oil were not affected. Rosin oil, oil of turpentine, cholesterol, and the unsaponifiable portions of wool grease yielded black masses from which optically inactive products were extracted by light petroleum.   H. W.

Structure of Acetylene. ALBERT P. MATHEWS (*J. Physical Chem.*, 1913, **17**, 320—321. Compare this vol, ii, 494).—The total number of valencies in acetylene calculated from the critical data by the author's formula is ten. The formula of acetylene at its critical point is therefore H—C≡C—H, and not C≡C≡H₂.   R. J. C.

Preparation of βγ-Dihalogen isoPentanes by the Chlorination of β-Halogen isoPentane. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 257600).—When the vapours of monohalogenated tertiary isopentanes are treated with chlorine (or bromine), they readily furnish a satisfactory yield of the technically important βγ-dihalogen isopentanes, and the preparation of βγ-dichloroisopentane, b. p. 60°/60 mm., from β-chloroisopentane is described. F. M. G. M.

The Preparation of Carbon Tetraiodide. MARCEL LANTENOIS (Compt. rend., 1913, 156, 1385—1387).—A critical study of the various methods recommended for the preparation of carbon tetraiodide (compare Spindler, A., 1886, 434; Moissan, A., 1891, 1420; Robineau and Rollin, A., 1895, i, 123). The author adopts Spindler's method, but prefers to replace the calcium iodide with lithium iodide, which gives a very pure product on heating it with excess of carbon tetrachloride in a vacuum in a sealed tube at 90—92° for five days. The best solvents for carbon tetraiodide are benzene, acetone, and carbon disulphide. W. G.

Higher Tertiary Alcohols Derived from Palmitic and Stearic Esters. HUGH RYAN and THOMAS DILLON (Proc. Roy. Irish Acad., 1912, B, 29, 235—245).—A series of tertiary alcohols has been prepared by the action of Grignard's reagents on esters of palmitic and stearic acid. The latter were readily obtained by the addition of a few c.c. of concentrated sulphuric acid to a hot solution of the acid in excess of the requisite alcohol, the yields in every case being more than 90% of the quantity theoretically obtainable. The following esters were obtained in this manner: methyl palmitate, needles, m. p. 28°; ethyl palmitate, long needles, m. p. 24·2°; n-propyl palmitate, needles, m. p. 18·8—19·2°; methyl stearate, needles, m. p. 38°; ethyl stearate, needles, m. p. 31°; n-propyl stearate, prisms, m. p. 28·6°.

For the preparation of tertiary alcohols, the solid ester was added in small portions to an ethereal solution of the necessary Grignard's reagent. There were thus obtained: dimethylpentadecylcarbinol, $C_{18}H_{38}O$, needles, m. p. 35°; diethylpentadecylcarbinol, curved needles, m. p. 34—35°; diphenylpentadecylcarbinol, prisms, m. p. 47—48°; dimethylheptadecylcarbinol, needles, m. p. 44—45°; diethylheptadecylcarbinol, needles, m. p. 44—45°; dipropylheptadecylcarbinol, needles, m. p. 28—30°; diphenylheptadecylcarbinol, long, curved needles, m. p. 58°. The action of an ethereal solution of magnesium naphthyl bromide on methyl stearate led to the formation of naphthyl heptadecyl ketone, $C_{17}H_{35}·CO·C_{10}H_7$, m. p. 55°.

Diethylheptadecylcarbinyl acetate was obtained as an oily liquid, which solidified when placed in iced water, by the action of acetyl chloride on diethylheptadecylcarbinol.

Dimethylpentadecylcarbinol, when heated on the sand-bath with sodium acetate and acetic anhydride, yielded a mixture of the corresponding acetate and unsaturated hydrocarbon. A similar result was obtained with diethylheptadecylcarbinol.

Dimethylheptadecylcarbinol was apparently not affected when heated with potash-lime at 250°. At 300°, however, unsaturated substances

were produced, but no evolution of hydrogen was observed. Diphenyl-heptadecylcarbinol similarly yielded unsaturated substances at 300°.

H. W.

Basic Properties of Oxygen. II. OTTO MAASS and DOUGLAS MCINTOSH (*J. Amer. Chem. Soc.*, 1913, **35**, 535—543).—In an earlier paper (A., 1912, i, 825) it has been shown that the compounds formed by the union of halogens or halogen hydrides with organic substances containing oxygen differ in many respects from molecular aggregates containing water or alcohol of crystallisation. In order to ascertain whether such compounds exist in solution, conductivity determinations have been made of the two-component systems of hydrochloric acid with ethyl and methyl ethers and with ethyl and methyl alcohols over the complete concentration range at −89°. The results are compared with the freezing-point curves of the different systems. In the case of methyl ether, two compounds are formed, namely, Me_2O,HCl and $Me_2O,4HCl$ (?). With ethyl ether, three compounds are produced: Et_2O,HCl, m. p. −92°; $Et_2O,2HCl$, m. p. −88°; and $Et_2O,5HCl$, m. p. −89°. Methyl and ethyl alcohols each yield only one compound, namely, $MeOH,HCl$, m. p. −62°, and $EtOH,HCl$, m. p. −65°. The conductivity curves indicate the probability of the existence of compounds in solution.

E. G.

A Derivative of Quinquevalent Tungsten. ARTHUR FISCHER and LOUIS MICHIELS (*Zeitsch. anorg. Chem.*, 1913, **81**, 102—115. Compare this vol., ii, 513).—The electrolysis of a solution of tungsten hexachloride in absolute alcohol gives at the platinum cathode a green, crystalline compound, $C_6H_{16}O_3Cl_2W$. It is decomposed by hot alcohol, but may be recrystallised from a mixture of alcohol and chloroform at 60°, cooling in ice. The compound forms bright green leaflets, with metallic lustre and slight fluorescence. It is slowly decomposed by hot water, yields the blue oxide when strongly heated, and gives the iodoform reaction. More than two-thirds of the carbon is evolved on heating in the form of ethylene. Oxidation with permanganate indicates that the tungsten is quinquevalent. The reactions indicate the composition $WCl_2(OEt)_3$, but the molecular weight is double this, and the exact constitution is uncertain.

C. H. D.

Catalytic Actions of Colloidal Metals of the Platinum Group. IX. The Hydrogenation of Egg-lecithin. CARL PAAL and HERMANN OEHME (*Ber.*, 1913, **46**, 1297—1304).—As in previous experiments with certain fats (A., 1908, i, 599; 1909, i, 358), so also it has been found possible to reduce egg-lecithin to a crystalline substance. Merck's reddish-brown, wax-like egg-lecithin had the iodine value, 55·3, but the volume of hydrogen absorbed in presence of colloidal palladium in 90% alcoholic solution was higher than this value would predict, being about 59 c.c. instead of 48·4 c.c. per 1 gram. The *hydrolecithin* partly separates from the solution, and may be recrystallised from chloroform and acetone as a white powder which sinters at 83—84°. On hydrolysis with barium hydroxide, it gave glycerol, phosphoric acid, and choline, which was identified as the

aurichloride, whilst the fatty acids recovered from the soap were found, after fractional crystallisation, to contain chiefly stearic acid, which would arise from the unsaturated C_{18}-acids of egg-lecithin. The presence of small quantities of acids of lower molecular weight, probably myristic, decoic, or lauric acids, showed that the substance and consequently the starting material were not quite homogeneous. Egg-lecithin is, however, chiefly a palmityl-linolyl-lecithin, and the analysis of the hydrolecithin agreed fairly well with $C_{42}H_{86}O_9NP$, the formula of a palmityl-stearyl-lecithin. J. C. W.

Uranyl Formate. GASTON COURTOIS (*Bull. Soc. chim.*, 1913, [iv], 13, 449—454).—The properties of *uranyl formate*, $(HCO)_2UO_2,H_2O$, which is obtained in non-deliquescent, yellow octahedra by digesting the hydrated oxide, UO_3,H_2O, with dilute formic acid at 80°, are very different in many respects from those described by Œchsner de Coninck and Raynaud (this vol., i, 333). When crystallised from ice water, it still contains $1H_2O$, and it is not dehydrated by prolonged sojourn in a vacuum desiccator. When dried in this manner, it is stable up to 100°, loses water at 150°, but also formic acid. A moist sample loses water and formic acid at 100°, and becomes insoluble. The solubilities are 7·2% in water at 15°, 4·9% in methyl alcohol at 18°, only slightly soluble in concentrated formic acid or alcohol, insoluble in other organic media.

The concentrated solution slowly deposits a *basic* salt in the cold and dark, quickly on boiling, in the form of yellowish-white, truncated prisms of the composition $(HCO)_2UO_2,H_2O$, $UO_3,2H_2O$. Prolonged boiling with water results in the acid, UO_3,H_2O. When exposed to light for some time, dilute solutions of the formate gradually deposit this basic salt mixed with a small amount of a violet hydrate of uranoso-uranic oxide. Even in methyl alcohol no brown uranium oxide was obtained, but the above violet substance, which was transformed into the pale yellow oxide, $UO_3,2H_2O$, in the air, and into the yellowish-white acid, UO_3,H_2O, on boiling with water.

J. C. W.

Molecular Association of Acetic Acid. ÉMILE BAUD (*Bull. Soc. chim.*, 1913, [iv], 13, 435—438).—According to the surface tension measurements of Ramsay and Shields (A., 1894, ii, 179), acetic acid exists in double molecules at the ordinary temperature. This was found to be the case when the acid is mixed with some organic solvents (A., 1912, ii, 233, 331, 1147), and is again confirmed by cryoscopic measurements in nitro- and chloro-benzene. The fact holds good even for strong solutions, from which it follows that the pure acid is bimolecular, and that the solvent has no associating influence in these cases.

Formic acid, however, like water, has a dissociating effect and the unimolecular value is obtained. The freezing-point curve for mixtures of the two acids does not indicate the formation of a compound, but it is assumed that combination does take place, since the heat absorbed on mixing the two substances is much less than the heat of dissociation of the double molecules. [An equilibrium between the double molecules

and the mixed molecules, $(C_2H_4O_2)_2 + (CH_2O_2)_2 \rightleftharpoons 2(C_2H_4O_2,CH_2O_2)$, would require that in a dilute solution of acetic acid in formic acid, the acetic acid molecule would produce two molecules of the mixed acid and cause an excessive depression of the freezing point, leading, therefore, to the unimolecular value for the molecular weight.

J. C. W.

Margaric Acid and its Relations to Palmitic and Stearic Acids. ROBERT F. RUTTAN (*8th Inter. Cong. Appl. Chem.*, 1912, **25**, 431—442).—The history of margaric acid is related, a method of preparing the acid by the Grignard reaction is described, and the chief constants of the acid are recorded in comparison with those of palmitic and stearic acids.

When cetyl iodide is treated with magnesium in ether, in presence of iodine as a catalyst, micaceous crystals of the organo-magnesium compound separate. If the mixture is then treated with carbon dioxide, a mixture of ditriacontane and margaric acid is formed, the yield of the acid being 50% of the theoretical under the best conditions, which include the use of dry reagents throughout the operations. A method for the separation of the hydrocarbon and acid is described. Margaric acid crystallises in colourless, bulky, shining plates, melts at 59·9—60° (corr.), and solidifies at 58·8°. It has D 0·8532 at its melting point, $n = 1·4342$ at 60°, and the coefficient of expansion is $6·65 \times 10^{-4}$ at 60—80°. The following quantities (grams) dissolve in 100 grams of dry alcohol at the temperatures named : 0°, 1·53 ; 5·4°, 2·42 ; 10°, 4·12 ; 15°, 6·72 ; 21°, 13·4 ; 28°, 32·14. Methyl margarate, m. p. 29°, forms waxy scales. Ethyl margarate, m. p. 27·5°, crystallises in waxy plates. *Ethylene margarohydrin*, m. p. 53·2°, forms pearly scales, and *ethylene dimargarate*, m. p. 70·4°, glistening plates.

Saponification of Triglycerides. JULIUS MEYER (*Chem. Zeit.*, 1913, **37**, 541—542).—The author criticises the experiments of Fortini (A., 1912, i, 826) on the saponification of triolein with alkali hydroxide in alcohol. The latter found that the curves obtained by plotting (1) quantity of triglyceride hydrolysed against time, or (2) acetyl number against time, were composed of three parts corresponding with (*a*) formation of diglyceride ; (*b*) formation of monoglyceride, and (*c*) formation of free fatty acid.

According to the author, the amount of alkali consumed is not a measure of the quantity of triglyceride saponified, since a portion of it is used in decomposing di- and mono-glycerides (compare Kellner, A., 1909, i, 357, 548, 759). Also, by plotting alkali consumed against time, a continuous curve is obtained in the saponification of triacetin in homogeneous solution by 0·01 and 0·02N potassium hydroxide (Meyer, A., 1909, ii, 803). Further, the determination of the acetyl number after definite intervals of time is not a satisfactory method of following the course of the reaction, since, particularly with the unsaturated oleic acid and its glycerides, this number depends greatly on the conditions under which the determination is executed, and is further complicated by the decomposition of the triglyceride into olein

acetate and glycerol occurring with intermediate formation of di- and mono-glycerides (compare Kremann, A., 1905, ii, 630; 1908, i, 120; Fanto and Stritar, 1908, i, 499).　　　　H. W.

The Behaviour of Paints Under the Conditions of Practice, with Special Reference to the Aspersions Cast on Lead Paints. HENRY E. ARMSTRONG and C. A KLEIN (*J. Soc. Chem. Ind.*, 1913, **32**, 320—331).—This communication is, to a great extent, critical and polemical against the work of Baly (*The Oil and Colour Trades Journal*, 1911, 1518; A., 1912, i, 533), and the report of Breton in connexion with lead paints. The experimental part deals with the formation of volatile products from linseed and other oils and the ordinary materials used in making paints, and with the test for lead in the volatile products, if any, from paint materials. The leaf of the common shrub, *Aucuba Japonica*, or the spotted Japanese laurel, is used as a test for volatile products, in the presence of which it blackens more or less rapidly.

The conclusions arrived at are: The vapours produced during the drying of white-lead pastes and paints do not contain lead. The vapours given off as paints dry consist of turpentine for the most part, together with oxidation products of the oil; the latter are common to paints generally containing oil so treated that it will dry. The oxidation products formed from the oil during drying are harmless under the conditions of practice. The toxic effects sometimes experienced from drying paints are to be ascribed to turpentine; in many cases effects which have been regarded as due to lead-poisoning are attributable to other causes, especially to turpentine. The dangers attending the use of lead compounds are only the well-known mechanical dangers.　　　　T. S. P.

Cerebronic Acid. II. PHŒBUS A. LEVENE and C. J. WEST (*J. Biol. Chem.*, 1913, **14**, 257—266. Compare A., 1912, i, 936).— Previous work indicated that cerebronic acid has the structure of an α-hydroxypentacosoic acid; on reduction the acid formed a hydrocarbon, m. p. 54—57°. According to Krafft and Marie, *n*-pentacosane has m. p. 53·5—54°. The experiments were repeated with a larger supply of material, and the melting point came out at the latter figure. By reduction of the acid, $C_{24}H_{48}O_3$, obtained by oxidation of cerebronic acid, a hydrocarbon, melting at 51—52°, was obtained, which is the melting point of normal tetracosane. Cerebronic acid is a α-hydroxy-*n*-pentacosoic acid.

Acetylcerebronic acid, $C_{25}H_{49}O_3$, obtained by the action of acetic anhydride on cerebronic acid, is a white, crystalline solid, m. p. 55·5—56°, and solidifies at 53—54°.　　　　W. D. H.

Formation of β-Ketone Esters by the Application of Reformatsky's Reaction. TREAT B. JOHNSON (*J. Amer. Chem. Soc.*, 1913, **35**, 582—585).—Fittig and Daimler (A., 1887, 361) have shown that ethyl chloroacetate reacts with ethyl oxalate in presence of amalgamated zinc with formation of ethyl ketipate. Reformatsky, in his work on the synthesis of dibasic hydroxy-acids (A., 1896, i, 206)

found that ethyl α-bromopropionate reacts with ethyl formate with production of ethyl β-hydroxy-αα-dimethylglutarate, but he obtained no evidence of the formation of ethyl formylpropionate corresponding with Fittig and Daimler's ethyl ketipate. In attempting, however, to prepare ethyl β-hydroxyglutarate from ethyl formate and ethyl chloroacetate (A., 1899, i, 516), he obtained ethyl trimesate as the chief product of the reaction, this having been formed by a condensation of ethyl formylacetate. The production of ethyl formylacetate and ethyl ketipate are analogous, and represent the first stage of Reformatsky's synthesis.

These results suggested that perhaps other esters besides ethyl formate and ethyl oxalate might undergo similar condensations with esters of halogen-substituted acids, and this has been found to be the case. The reaction has been applied to ethyl ethoxyacetate, ethyl α-ethoxypropionate, ethyl bromoacetate, and ethyl α-bromopropionate, and the following esters have been obtained: *Ethyl γ-ethoxyaceto acetate*, $OEt \cdot CH_2 \cdot CO \cdot CH_2 \cdot CO_2Et$, b. p. 110°/20—21 mm., 116—120°/26—27 mm., 120—125°/30 mm., and 130—136°/43 mm. *Ethyl γ - ethoxy - α - methylacetoacetate*, $OEt \cdot CH_2 \cdot CO \cdot CHMe \cdot CO_2Et$, b. p. 113—116°/18—20 mm., and 116°/24 mm. *Ethyl γ ethoxy-γ-methylacetoacetate*, $OEt \cdot CHMe \cdot CO \cdot CH_2 \cdot CO_2Et$, b. p. 110—115°/19 mm. *Ethyl γ-ethoxy-αγ-dimethylacetoacetate*, $OEt \cdot CHMe \cdot CO \cdot CHMe \cdot CO_2Et$, b. p. 108—115°/16 mm.   E. G.

Real and Supposititious Oxalomalonic Esters and Applicability of Methanetricarboxylic Ester for Synthetic Purposes. ROLAND SCHOLL and WILHELM EGERER (*Annalen*, 1913, 397, 301—366).— The triethyl oxalomalonate (ethyl ketoethanetricarboxylate) and corresponding acid described by Kurrein (A., 1905, i, 413) are a mixture of ethyl oxalate and malonate, and a mixture of hydrated oxalic acid and malonic acid respectively. Also the substance, b. p. 220°/10 mm., obtained by Bouveault in 1898 from ethyl sodiomalonate and ethyl oxalic chloride, and described by him as triethyl oxalomalonate, $CO_2Et \cdot CO \cdot CH(CO_2Et)_2$, cannot be this compound, as the sequel proves.

[With EMIL HEUSER.]—Methyl dichloromethoxyacetate,
$$OMe \cdot CCl_2 \cdot CO_2Me,$$
which is obtained in 80—90% yield by heating methyl oxalate and phosphorus pentachloride (1½ mols.) at 130—135° for thirty hours, is converted into methyl chloropyruvate, $CO_2Me \cdot COCl$, to the extent of 60% by heating it with a small quantity of platinum black in a bath at 200° until the temperature cannot be raised above 140—160°; the methyl oxalic chloride, b. p. 117—118°, is then removed by distillation, and the residue again heated, a quantity of platinum black being again added if necessary.
Methyl sodiomalonate and methyl chloropyruvate in equal molecular quantities react in dry ether in a freezing mixture to form methyl malonate and *methyl dioxalomalonate* (*methyl αγ-diketopropane-αββγ-tetracarboxylate*), $C(CO_2Me)(CO \cdot CO_2Me)_2$; after the removal of the ether by a current of air at 25°, the residue is vigorously shaken with ice-water, by which all products are dissolved except the tetracarboxylate.

Methyl dioxalomalonate, m. p. 97·5 —98°, colourless needles or prisms, which can bo also prepared in a similar manner from methyl chloropyruvate and methyl sodio-oxalomalonate (see below), is unattacked by alkaline potassium permanganate or by bromine, and is therefore not an *O*-derivative, $CO_2Me \cdot CO \cdot C(CO_2Me) \colon C(OMe) \cdot O \cdot CO \cdot CO_2Me$ or
$$C(CO_2Me)_2 \colon C(CO_2Me) \cdot O \cdot CO \cdot CO_2Me,$$
but is a very reactive substance in other ways. It is decomposed by water, slowly at the ordinary temperature and rapidly by heating, into oxalic acid and methyl malonate. It is decomposed in the same manner by boiling methyl alcohol, with or without potassium hydroxide. Ammonia, phenylhydrazine, and aniline also decompose the tetracarboxylate, producing methyl malonate and oxamide, oxalic acid diphenylhydrazide, or methyl oxanilate respectively.

By heating at 180—200°, methyl dioxalomalonate loses carbon monoxide and is converted into *methyl oxalomethanetricarboxylate* (*methyl ketoethanetetracarboxylate*), $CO_2Me \cdot CO \cdot C(CO_2Me)_3$, m. p. 91—92°, b. p. 285—286° or 179—180°/15 mm., colourless plates, which is also prepared by heating methyl chloropyruvate and methyl sodiomethanetricarboxylate in benzene (see below). The ester is remarkably stable when heated, being almost unchanged after boiling for one and a-half hours. It does not give a coloration with alcoholic ferric chloride. When boiled with methyl alcohol, the ester is rapidly converted into methyl oxalate and *methyl methanetricarboxylate*, $CH(CO_2Me)_3$, m. p. 45—46°, b. p. 242·7° (corr.) or 128°/15 mm., colourless prisms. Methyl methanetricarboxylate is also obtained by heating a suspension of methyl sodiomalonate in benzene with methyl chloroformate ; it is soluble in dilute sodium hydroxide or carbonate, and forms with methyl-alcoholic sodium methoxide a *sodio*-derivative, $C_7H_9O_6Na$, colourless needles. Methyl methanetricarboxylate exists as the ketonic modification in the crystalline state, but when fused or in alcoholic solution it is partly changed to the enolic form, since the reddish-brown coloration produced by ferric chloride gradually becomes more intense.

Many attempts have been made to prepare methyl oxalomalonate (methyl ketoethane-*aaβ* tricarboxylate) from methyl sodiomalonate and methyl chloropyruvate under different conditions of temperature and concentration, but the principal product is always methyl dioxalomalonate. The desired ester, however, has been obtained from methyl dioxalomalonate by careful decomposition with methyl alcohol or methyl sodiomalonate. The preparation is difficult because methyl oxalomalonate itself is decomposed into methyl oxalate and methyl malonate by methyl alcohol. A 10% solution of methyl dioxalomalonate in benzene is kept with an equal molecular quantity of methyl alcohol for thirty days at the ordinary temperature, or at least four days at 50°, the product is distilled under about 12 mm. pressure, and the ethereal extract of the residue is fractionally crystallised, whereby *methyl oxalomalonate*, $CO_2Me \cdot CO \cdot CH(CO_2Me)_2$, m. p. 49—50°, colourless needles, is obtained, the yield being about 50% of the amount ascertained volumetrically (see below). The ester is also obtained by treating a suspension of methyl sodiomalonate (2 mols.) in benzene at 50° with methyl dioxalomalonate (1 mol.), removing the yellow precipitate (sodio-derivatives of methyl oxalomalonate and methyl

malonate), suspending it in ether at 0°, and treating it with dilute sulphuric acid at 0°; the ester is obtained from the ethereal solution. A third method of preparing methyl oxalomalonate from methyl sodiomalonate and methyl chloropyruvate is described.

Methyl oxalomalonate forms colourless solutions in aqueous sodium hydroxide or carbonate, and does not react in ether with sodium. At 120—130° it decomposes quantitatively into carbon monoxide and methyl methanetricarboxylate, and thus reacts as the ketonic modification. By titration with alcoholic bromine and β-naphthol by Meyer's method, it is shown that the ester is entirely enolic in alcohol or benzene, but contains about 7%, 21%, and 94% (?) of the ketonic modification in chloroform, acetone, and glacial acetic acid respectively. Meyer's method can also be employed to show that the maximum (molecular) percentage of methyl oxalomalonate obtained from equal molecular quantities of methyl alcohol and methyl dioxalomalonate in benzene (at 18° or at 50°) is about 71%.

The series of ethyl esters corresponding with the preceding methyl esters has been prepared. Ethyl sodiomalonate and ethyl chloropyruvate react in ether to form ethyl malonate and a mixture of ethyl oxalo- and dioxalo-malonates, from which the latter cannot be isolated. By distillation under 15 mm. pressure, the mixture decomposes, evolves carbon monoxide, and produces *ethyl methanetricarboxylate*, $CH(CO_2Et)_3$, m. p. 28·5°, and *ethyl oxalomethanetricarboxylate*, $CO_2Et\cdot CO\cdot C(CO_2Et)_3$, b. p. 191—192°/15 mm. (Bouveault's so-called ethyl oxalomalonate).

By treating an ethereal solution of the preceding mixture of ethyl oxalo- and dioxalo-malonates with sodium, *ethyl sodio-oxalomalonate*, $C_{11}H_{15}O_7Na$, is obtained as a white precipitate, from which *ethyl oxalomalonate*, D_4^{17} 1·1147, is obtained. Ethyl oxalomalonate is soluble in dilute sodium hydroxide or carbonate, but is not attacked by sodium except in the presence of a little ethyl malonate. It develops a red coloration with alcoholic ferric chloride, decomposes by heating into carbon monoxide and ethyl methanetricarboxylate, and is decomposed by water or phenylhydrazine in the same manner as the methyl ester.

Ethyl dioxalomalonate, $C(CO_2Et)_2(CO\cdot CO_2Et)_2$, is obtained from ethyl chloropyruvate and ethyl sodio-oxalomalonate in ether, and decomposes by heating.

Conrad and Guthzeit, Michael, and others have tried to utilise methanetricarboxylic esters for synthetic purposes. Their efforts have been unsuccessful, since they used alcohol, by which alkyl methanetricarboxylates are decomposed into alkyl malonates. In the absence of alcohol, alkyl sodiomethanetricarboxylates can be used for synthetic purposes as effectively as ethyl sodioacetoacetate or sodiomalonate, higher temperatures, however, being necessary.

Dimethyl ethyl methanetricarboxylate, $CO_2Et\cdot CH(CO_2Me)_2$, prepared from methyl sodiomalonate and ethyl chloroformate, has b. p. 240—241°, or 138—139°/12 mm., and forms with sodium ethoxide a white *sodio*-derivative. Ethyl sodiomethanetricarboxylate reacts with methyl iodide at 140° to form *ethyl ethane - aaa - tricarboxylate*, $CMe(CO_2Et)_3$, b. p. 250°, or 130°/11 mm., and with ethyl iodide, in a

similar manner, to form *ethyl propane-aaa-tricarboxylate*, $CEt(CO_2Et)_3$, b. p. 258°, or 146°/17 mm.; the latter ester, which has a bitter taste, is converted into ethyl carbonate and ethyl sodioethylmalonate by alcoholic sodium ethoxide.

Ethyl sodiomethanetricarboxylate and acetyl chloride react, finally on the water-bath, to form *ethyl acetylmethanetricarboxylate* (*ethyl β-ketopropane-aaa-tricarboxylate*), $C(CO_2Et)_3 \cdot COMe$, b. p. 253° or 147—148°/14 mm., and with benzoyl chloride to form *ethyl benzoylmethanetricarboxylate*, $C_{17}H_{20}O_7$, b. p. 214°/14 mm. Methyl sodiomethanetricarboxylate and methyl chloro-formate react at 120° to form *methyl methanetetracarboxylate*, $C(CO_2Me)_4$, m. p. 74—75°, b. p. 295° (corr.)/735 mm., or 163°/12 mm., colourless, tasteless needles, which is not attacked by alkaline potassium permanganate or by bromine, and is converted into malonic acid by dilute sulphuric acid and into methyl carbonate and methyl sodiomethanetricarboxylate by alcoholic sodium methoxide. *Dimethyl diethyl methanetetracarboxylate*, b. p. 293°, or 167°/11 mm., and *ethyl methanetetracarboxylate*, m. p. 13·5°, b. p. 304° (corr.)/735 mm., or 173·5°/12 mm., D$_?^?$ 1·0886, both of which have a bitter taste, are also described.

Ethyl oxalomethanetricarboxylate (see above) is also obtained from ethyl sodiomethanetricarboxylate and ethyl chloropyruvate in benzene.

C. S.

Effect of Heating Paraformaldehyde with a Trace of Sulphuric Acid. JOHN G. M. DUNLOP (*Proc. Camb. Phil. Soc.*, 1913, **17**, 180—181).—When a mixture of paraformaldehyde and sulphuric acid is heated at 115° in a sealed tube, bent in such a manner that one end is heated while the other end is kept cool by immersion in a beaker of water, a mobile distillate is obtained, which, when fractionated, yields methyl formate and a liquid, b. p. 95—96°, still under investigation, which appears to be a polymeride of formaldehyde. The yield of methyl formate is very variable and depends on the amount of sulphuric acid and also on the temperature. With about six drops of sulphuric acid to ten grams of trioxymethylene, a yield of about one to two grams of ester appears to be usual. With five grams of acid to the same weight of trioxymethylene, great charring takes place and practically no ester is formed.

H. W.

Methylation of *iso*Valerone by means of Sodamide and Methyl Iodide. Tetramethyl*iso*valerone or βγεεζ-Hexamethylheptan-δ-one. ALBIN HALLER and EDOUARD BAUER (*Compt. rend.*, 1913, **156**, 1295—1298. Compare this vol., i, 488).—By the action of sodamide on *iso*valerone dissolved in benzene, followed by addition of methyl iodide according to the usual method, a liquid was obtained which, after twice repeating this methylation, gave, on fractional distillation, *βγεζ-tetramethylheptan-δ-one*, b. p. 76—78°/13 mm., yielding only traces of an oxime, and *βγγεζ-pentamethylheptan-δ-one*, b. p. 88—89°/13 mm., which gave no oxime, and was not decomposed on boiling with sodamide in benzene. The last substance on further methylation with sodamide and methyl iodide in toluene yielded *βγεεζ-hexamethylheptan-δ-one*, b. p. 107—109°/14 mm., which gave

neither oxime nor semicarbazone, and was not decomposed by sodamide in boiling toluene. On reduction with sodium in alcohol, it yielded the corresponding $\beta\gamma\gamma\epsilon\epsilon\zeta$-*hexamethylheptan-$\delta$-ol*, b. p. 115—117°/13 mm., giving a *phenylurethane*, m. p. 91—92°.   W. G.

Reactions of Methylene. IV. The Decomposition of Ketens at High Temperature. HERMANN STAUDINGER and R. ENDLE (*Ber.*, 1913, **46**, 1437—1442. Compare A., 1912, i, 245)—Since it has been shown (this vol., i, 604) that dicarbon dioxide is incapable of existence, but decomposes into carbon monoxide with rupture of the ethylenic bond, whilst, generally, ethylene derivatives are remarkably stable towards heat, the authors have been led to examine the behaviour of ketens at high temperatures, as these substances form an intermediate link between dicarbon dioxide and the true ethylene derivatives.

The experiments were performed in a quartz tube closed at one end at which the substance was placed. In the middle of the tube a silver spiral was placed which could be maintained at 600—700°. The tube was further connected with a suitable condensing arrangement. Previous to an experiment the tube was exhausted. The substance was then vaporised, and the vapours conducted over the heated spiral.

Diphenylketen, when heated in the above manner, yielded fluorene in accordance with the scheme:

$$(C_6H_5)_2C{:}CO \longrightarrow \frac{C_6H_5}{C_6H_5}{>}C{<} + CO \longrightarrow \frac{C_6H_4}{C_6H_4}{>}CH_2 + CO.$$

Dimethylketen, obtained by heating tetramethyldiketo*cyclo*butane, gave propylene and tetramethylethylene:

$$CMe_2{:}CO \longrightarrow CMe_2{<} \longrightarrow CH_3{\cdot}CH{:}CH_2\,; \quad 2CMe{<} \longrightarrow CMe_2{:}CMe_2.$$

In similar circumstances, diphenylethylene and tetraphenylethylene were not altered, whilst only slight decomposition occurred with diphenyldichloroethylene. Diphenylmethane also underwent no change. At 250°, diphenylbromomethane was converted into tetraphenylethylene and hydrogen bromide. When the silver spiral was replaced by fragments of porcelain, diphenylbromomethane and diphenylchloromethane yielded at 700° tetraphenylethylene instead of fluorene, so that possibly the course of the reaction depends on the contact material.

Phenylcarbimide and phenylthiocarbimide were not affected by a silver spiral at 700°, or by a platinum spiral heated to glowing.
                                                                  H. W.

Esterification of Dihydroxyacetone with Phosphates. ALEXANDER VON LEBEDEV (*Zeitsch. physiol. Chem.*, 1913, **84**, 305).— Polemical (compare Euler and Johansson, A., 1912, i, 750).
                                                                  E. F. A.

The Action of Ultraviolet Light on Sucrose. YNGVE DALSTROM (*Arkiv. Kem. Min. Geol.*, 1913, **4**, No. 30, 1—14).—The source of ultraviolet light was an arc burning between carbon or iron electrodes. The apparatus was similar to that used by Euler and

Ohlén (A., 1911, i, 524), the temperature being 70°. The progress of any reaction taking place was followed by observing the change in rotation of the solutions used, and by titrating any acid formed with standard barium hydroxide solution.

The action of the light of short wave-length produced by the above-mentioned arcs consists, in the first instance, in the formation of an organic acid, which then brings about the hydrolysis of the remaining sucrose. Any direct action of the ultraviolet light on the hydrolysis can only be very small. T. S. P.

Action of Reducing Agents on the Chloraloses. MAURICE HANRIOT and ANDRÉ KLING (*Compt. rend.*, 1913, **156**, 1380—1382).— a- and β-Chloralose and galactochloralose are reduced in aqueous solution by aluminium activated with mercury, one of the chlorine atoms being replaced by hydrogen, and the products obtained are the same as in the action of ammonia on the chloraloses (compare A., 1911, i, 524, 525). In alkaline solution, sodium amalgam removes a second atom of chlorine, and from a-chloralose a *compound*, $C_7H_{11}O_6 \cdot CH_2Cl$, m. p. 168°, is obtained. β-Chloralose yields a similar *compound*, m. p. 166°, giving a *dibenzoyl* derivative, needles, m. p. 149°, and on oxidation with nitric acid it yields a non-crystalline substance giving with hydrazine hydrate a *compound*, $C_7H_7O_5Cl,N_2H_4$, white needles, m. p. 170°.

Sodium in liquid ammonia removes the third chlorine atom from the chloralose, but the product of the action could not be crystallised, the action seeming to lead to the destruction of the chloralose nucleus. W. G.

Pseudo-crystals of Starch and Crystals of Dextrose. GIOVANNI MALFITANO and (Mlle.) A. N. MOSCHKOV (*Compt. rend.*, 1913, **156**, 1412—1415. Compare A., 1910, i, 301, 817).—The so-called crystals of starch, when examined microscopically, although resembling crystals of dextrose fairly closely, are found not to have a true crystalline form. These particles of starch have not the polyhedric form, neither do they exhibit the phenomenon of birefringence. W. G.

The Molecular Size of Dextrin-β. WILHELM BILTZ and WILHELM TRUTHE (*Ber.*, 1913, **46**, 1377—1380. Compare Pringsheim and Langhans, A., 1912, i, 832).—The osmotic pressures exerted by dilute solutions of dextrin-β in a cell composed of collodion impregnated with copper ferrocyanide have been measured directly, and the calculated molecular weights plotted against concentration. By extrapolation for infinite dilution, the value 950 ± 50 is obtained, which confirms the expectation that dextrin-β is a hexa-amylose. The fact that the curve rises rapidly with increasing concentration is not due so much to association as to the time required to reach equilibrium, for higher pressures and therefore lower molecular weights are obtained when the water column is allowed to sink to position than when it is made to rise. The method is being described

in another place. The results obtained for similar substances compare favourably with the values obtained by cryoscopic and other means.   J. C. W.

Cellulose. EDWARD G. PARKER (*J. Physical Chem.*, 1913, **17**, 219—229).—Lange's method of estimating cellulose by hydrolysing the non-celluloses with potassium hydroxide, and the various modifications of it which have been proposed, give untrustworthy results, as the yield of normal cellulose varies with slight variations in the time of boiling, concentration of alkali, and temperature. By heating in a paraffin bath at 130—140° under reflux, after a certain interval of time the yield of normal cellulose from absorbent cotton became constant. The time required for the hydrolysis of the non-celluloses was less with dilute potassium hydroxide within the limits used, a 1 or 2% solution requiring three hours and a 20% solution fifteen hours. It is suggested that the increased evolution of steam from the dilute solutions carried the non-celluloses more rapidly into suspension where the alkali could act on them.

The author's sample of cotton wool contained approximately 92—93% of normal cellulose, 4—5% of soluble cellulose, and 3·25% of water.

Samples of oxycellulose prepared by the action of hydrochloric acid and potassium chlorate and of cellulose reprecipitated from cuprammonium solution contain a much higher proportion of matter soluble in potassium hydroxide. It is suggested that the soluble part of cotton wool consists of oxy- and hydro-cellulose and that cotton reprecipitated from Schweitzer's reagent consists largely of oxycellulose.   R. J. C.

Esters of Cellulose with Benzoic Acid and their Derivatives. G. J. BRIGGS (*Zeitsch. angew. Chem.*, 1913, **26**, 255—256).—Hauser and Muschner have stated (this vol., i, 363) that they were unable to prepare the dibenzoate and tetrabenzoate described by Cross and Bevan. The author gives in detail the methods which were employed in the preparation of these derivatives of cellulose. Both esters are obtained by treating alkali cellulose with a 5—10% solution of benzoyl chloride in benzene, and are separated, first by treating the crude product with chloroform or glacial acetic acid in which the tetrabenzoate dissolves, and then by treating the residue with a cuprammonium solution which removes the unattacked cellulose.   W. H. G.

Oxycellulose. R. OERTEL (*Zeitsch. angew. Chem.*, 1913, **26**, 246—250).—The oxycelluloses prepared by the methods of Witz, Nastukoff, Vignon, or Faber and Tollens are not simple substances. An oxycellulose having properties differing from those already known and described in the literature is obtained by passing an electric current between platinum electrodes and through a solution of potassium chloride containing cellulose in suspension. Under this treatment a large proportion of the cellulose is decomposed and passes into solution, but if the electrolysis is not carried too far, a product

is obtained which is soluble in a 10% solution of sodium hydroxide and has a copper value of 21·0—29·6 according to the extent of the electrolysis, the reducing power becoming greater as the treatment is prolonged. If the electrolysis be carried sufficiently far, the product obtained dissolves in water, forming a stable, colloidal solution, and has a copper value as high as 39·5.

The oxycellulose prepared by the electrolytic method is rapidly destroyed by a hot solution of sodium hydroxide, and when dissolved in a cuprammonium solution gives a very limpid solution. It is converted by sulphuric acid into dextrose, but the yield is not so high as in the case of cellulose, for whereas 100 parts of the latter yield 111 parts of dextrose, 100 parts of oxycellulose yield only 100 parts of dextrose. Oxycellulose when acetylated, using zinc chloride as catalyst, yields an acetate, part of which is soluble in acetone and has $[a]_D - 17°$, and part in chloroform ($[a]_D - 19°$ to $- 20°$); the proportion of acetyl radicle present in the product is not so high as in cellulose triacetate.

The yield of cellobiose acetate from oxycellulose is also not so great as from cellulose. W. H. G.

Formation of Humic Substances by the Action of Polypeptides on Sugars. LOUIS C. MAILLARD (*Compt. rend.*, 1913, **156**, 1159—1160. Compare A., 1912, i, 13, 169; this vol., i, 165).—Glycylglycine like glycine itself readily reacts with xylose and dextrose in the presence of water, with the evolution of carbon dioxide and formation of brown humus-like substances, which are insoluble in boiling water and dilute acids, but partly soluble in ammonia and potassium hydroxide, from which solutions they are reprecipitated on neutralisation. Three samples of commercial peptones behaved similarly with the sugars. W. G.

Some Tetramethylammonium Compounds. JAROSLAV MIL-BAUER (*J. pr. Chem.*, 1913, [ii], **87**, 397—403).—The following tetramethylammonium salts are described: *perchlorate*, white crystals (solubility in cold water 1·126 : 100); *permanganate*, purple-red, tetragonal crystals, which readily decompose on exposure to moist air, and explode violently when heated. The *dithionate*, prepared by the interaction of the sulphate and barium dithionate in aqueous solution, forms lustrous, transparent, colourless cubes and octahedra. The *thiocyanate* crystallises in white, felted needles, the *stannichloride* in white, microscopic octahedra, and the *stannibromide* in pale yellow, microscopic octahedra. The *borate*, $(NMe_4)_3B_4O_7,5H_2O$, forms strongly refractive, transparent crystals, probably belonging to the triclinic system. The *sulphide* and *fluoride* could not be obtained in a pure condition. F. B.

Non-equivalence of the Five Valencies of Nitrogen. JAKOB MEISENHEIMER (*Annalen*, 1913, **397**, 273—300).—The author's explanation of the existence of amine-oxides in enantiomorphous configurations (A., 1912, i, 25) tacitly assumes the non-equivalence of the five valencies of the nitrogen atom. Many facts can be quoted in support

of the assumption, but it has now been definitely proved. Trimethylamine oxide reacts additively with an alkyl iodide, and its hydrochloride reacts with sodium alkyloxide, as follows:

$$Me_3NO + RI \longrightarrow Me_3N{<}^{OR}_{I} \xrightarrow{NaOH} Me_3N{<}^{OR}_{OH} \text{ (I).}$$

$$Me_3NO + HCl \longrightarrow Me_3N{<}^{OH}_{Cl} \xrightarrow{NaOR} Me_3N{<}^{OH}_{OR} \text{ (II).}$$
The position of the halogen atom in the ammonium salt is occupied by OH in substance (I) and by OR in substance (II). Several such pairs of isomerides have been prepared, and in every case the two substances are fundamentally different. The substances have not been isolated in the solid state, but by the evaporation of its aqueous solution, substance (I) decomposes quantitatively into trimethylamine, an aldehyde, and water, whereas substance (II) yields trimethylamine oxide and the alcohol R·OH. Pairs of isomerides of the types $Me_3N{<}^{OR}_{OR'}$ and $Me_3N{<}^{OR'}_{OR}$ have also been obtained; the evaporation of their solutions yields trimethylamine, an alcohol, and one aldehyde, the aldehyde always being that corresponding with the alkyl group of the alkyloxy-group not attached to the unique " fifth " valency of the quinquevalent nitrogen atom. Consequently, the two alkyloxy-groups are not attached to the nitrogen atom in the same manner.

The author discusses the constitutions of the isomerides $Me_3N{<}^{OR}_{OR'}$ and $Me_3N{<}^{OR'}_{OR}$, and gives reasons for rejecting formulæ:
$$Me_3N{:}O{<}^{R}_{OR'}$$

and $Me_3N{:}O{<}^{R'}_{OR}$, $[Me_3NO] \ldots R·OR'$ and $[Me_3NO] \ldots R'·OR$, and $[Me_3N \ldots OR]OR'$ and $[Me_3N \ldots OR']OR$, based on the oxonium, oxonium-ammonium, and (Werner's) ammonium theories respectively. A modification of the last theory is adopted. In Werner's formula of ammonium chloride, the nitrogen atom still remains in a sense tervalent; the four hydrogen atoms are attached to the nitrogen atom each by an amount of affinity less than that corresponding with a principal valency, so that the group NH_4 has an amount of residual affinity whereby it functions as a univalent group and is attached to the acid radicle. Objections can be raised against this view (compare Moore and Winmill, T., 1912, 101, 1673). The author is of opinion that in ammonium compounds the nitrogen is quinquevalent, all five atoms or groups being attached to it by principal valencies, four in an inner, the fifth in an outer, zone; the atom or group in the outer zone is not attached in any definite position, and therefore exerts no influence on the asymmetry of the molecule. The author's pairs of isomerides are consequently represented by the formulæ: $[Me_3N·OR]·OR'$ and $[Me_3N·OR']·OR$, which satisfactorily represent their behaviour.

[With KURT BRATRING.]—Hydrated trimethylamine oxide,

$$NMe_3O,2H_2O,$$

prepared best by Dunstan and Goulding's method (T., 1899, 75, 1005), can be dehydrated by heating under 10—12 mm. at a tempera-

ture not exceeding 150° until the greater part of the water has been
expelled; the temperature is then raised to 190—200°, when *trimethyl-
amine oxide*, NMe_3O, sublimes in colourless needles, m. p. 208°, which
are extremely hygroscopic. By boiling for three-quarters of an hour
with ethyl iodide in ethyl alcohol or with propyl iodide in propyl
alcohol, the anhydrous oxide is readily converted into additive *com-
pounds*, $OEt \cdot NMe_3I$, m. p. 122—125°, and $OPr \cdot NMe_3I$, m. p.
145—147°, respectively, both colourless, crystalline substances. By
treating a dilute aqueous solution of methoxytrimethylammonium
iodide with silver oxide and subsequently with cold hydrochloric acid
and evaporating, *methoxytrimethylammonium chloride*, $OMe \cdot NMe_3Cl$, is
obtained, but the evaporation of an alcoholic solution of the methoxy-
trimethylammonium hydroxide without the addition of hydrochloric
acid results in the formation of trimethylamine (isolated as the
platinichloride) and formaldehyde (isolated as the *p*-nitrophenyl-
hydrazone). Similar results are obtained by the evaporation of
alcoholic solutions of ethoxytrimethylammonium hydroxide and
propoxytrimethylammonium hydroxide, acetaldehyde and prop-
aldehyde, respectively, being formed. By treating trimethylamine
oxide hydrochloride, dissolved in the necessary alcohol, with the
calculated amount of sodium methoxide, ethoxide, or propoxide,
hydroxytrimethylammonium methoxide, ethoxide, and *propoxide* respec-
tively are produced, $OH \cdot NMe_3 \cdot OR$. By evaporation of their alcoholic
solutions, these substances yield no trimethylamine, and only a trace
of an aldehyde; the residue in all three cases is converted into
trimethylamine oxide hydrochloride by alcoholic hydrogen chloride.

[With J. DODONOW.]—*Tetramethylammonium ethoxide,*
$$NMe_4 \cdot OEt, EtOH,$$
hygroscopic crystals, is obtained by treating tetramethylammonium
chloride in anhydrous alcohol with the calculated amount of sodium
ethoxide, adding ether, and removing the sodium chloride by filtration
and the solvent by evaporation in a vacuum at 40°. *Alkyloxytrimethyl-
ammonium alkyloxides*, $[NMe_3 \cdot OR] \cdot OR'$, are obtained in alcoholic
solution by treating alkyloxytrimethylammonium iodides with alcoholic
sodium alkyloxides. The substances have not been isolated, but the
products of their decomposition by the evaporation of their alcoholic
solutions in a current of nitrogen have been examined. *Methoxytri-
methylammonium ethoxide* and *methoxytrimethylammonium propoxide*
each yield formaldehyde, *ethoxytrimethylammonium methoxide* and
ethoxytrimethylammonium propoxide each yield acetaldehyde, whilst
propoxytrimethylammonium methoxide yields propaldehyde.

[By the AUTHOR.]—It is probable that phosphonium compounds
have a constitution similar to that of ammonium compounds suggested
by the author; the existence of phosphorus pentachloride is not
evidence against the probability, since the equivalence of the five
chlorine atoms has not been proved. The additive compound of
phosphenyl chloride and bromine, therefore, should be different from
that of phosphenyl bromide and chlorine, the two substances having
the constitutions $[PPhCl_2Br]Br$ and $[PPhBr_2Cl]Cl$ respectively.
Experiment shows, however, that the two substances are identical.

C. S.

Action of Ethylene Dibromide, Methylene Iodide, and Iodine on Ethyl Aminocrotonate. ERICH BENARY (*Ber.*, 1913, **46**, 1375—1377).—Unlike chloroacetyl chloride, ethylene dibromide and methylene iodide do not form pyrrole derivatives on condensation with ethyl aminocrotonate in presence of pyridine, but they give rise to ethyl dihydrocollidinedicarboxylate and ethyl lutidinedicarboxylate respectively. When iodine is added to the sodium compound of ethylamino-crotonate in ether, *ethyl iodoaminocrotonate*, $NHI \cdot CMe \colon CH \cdot CO_2Et$, is obtained in soft leaflets, m. p. 83—84°, which are hydrolysed by dilute sulphuric acid to ethyl α-iodoacetoacetate (compare ethyl bromo-aminocrotonate, Behrend, A., 1900, i, 210).   J. C. W.

The Reaction Products of Ammonia on Ethyl Dicarbin-tetracarboxylate. ROLAND SCHOLL, KARL HOLDERMANN, and ARMIN LANGER (*Monatsh.*, 1913, **34**, 623—629).—Ethyl dicarbintetracarb-oxylate [ethyl ethylenetetracarboxylate] is best prepared by the method of Blank and Samson (A., 1899, i, 484). It reacts slowly with a saturated alcoholic solution of ammonia at the ordinary temperature, producing *ethyl α-aminoethane-ααββ-tetracarboxylate,*

$$NH_2 \cdot C(CO_2Et)_2 \cdot CH(CO_2Et)_2,$$
as an additive product. This is an oily liquid, which dissociates into its two components when distilled under reduced pressure and also regenerates ethyl ethylenetetracarboxylate when treated with nitrous acid. The stability of the amino-acid towards acid and alkali is believed to be incompatible with the alternative structure suggested by the two reactions just cited (compare Meister, A., 1888, 675).

If a bomb tube containing a mixture of liquid ammonia and ethyl ethylenetetracarboxylate is kept sealed at the ordinary temperature for sixty hours, tablet or prismatic crystals of *α-aminoethane-ααββ-tetracarboxylamide,* $NH_2 \cdot C(CO \cdot NH_2)_2 \cdot CH(CO \cdot NH_2)_2$, separate. This substance is unstable and smells of ammonia; it is decomposed by water, and when heated alone, gradually decomposes with final carbonisation.   D. F. T.

The Course of the Action of Ammonia on Ethyl Dicarbin-tetracarboxylate. ERNST PHILIPPI and ALFRED UHL (*Monatsh.*, 1913, **34**, 717—731. Compare preceding abstract).—The paper opens with a discussion of various theories as to the mechanism of amide formation.

Carefully dried ammonia was passed for twenty minutes, after all sign of heat evolution had disappeared, into a suspension of ethyl ethylenetetracarboxylate (ethyl dicarbintetracarboxylate) in absolute alcohol, and the resultant solution kept for three months; a yellowish-white, crystalline crust separated. The alcoholic mother liquid con-tained a little unaltered ester together with an oily additive *compound* of molecular proportions of ammonia and ester; *platinichloride,* yellow, microscopic, columnar crystals. The additive compound is believed to be *ethyl α-aminoethane-ααββ-tetracarboxylate,* the presence of the carboxyl groups having so increased the activity of the ethylenic linking of the original ester as to cause addition at this position; such addition of ammonia has been observed at the double bond of several ethylenic esters. When boiled for several hours with 2*N*-hydrochloric

acid, carbon dioxide is set free, leaving the hydrochloride of aspartic acid. A solution of the additive compound in hydrochloric acid when treated with nitrous acid regenerates ethyl ethylenetetracarboxylate; this behaviour is explained by the primary formation of the expected hydroxy-compound, which immediately passes into the ethylenic ester with loss of a molecule of water. The solid crust obtained in the initial experiment consisted of *α-aminoethane-ααββ-tetracarboxylamide*, a hygroscopic, unstable substance which decomposes on moderate heating. Altogether 89·6% of the original ester could be accounted for in the products. D. F. T.

Internally Complex Metallic Salts of Derivatives of Oxalic Acid and of Triformaldoxime. KARL A. HOFMANN and UDO EHRHARDT (*Ber.*, 1913, **46**, 1457—1466).—Various amido-derivatives of oxalic acid have been examined in connexion with the power of formation of internally complex salts, because their structure is such as to suggest an easy formation of a ring composed of five atoms. It is discovered that the stability of the complex salt depends on the number of amido- or imido-groups present, for, of the substances examined, oxamic acid shows least tendency, whilst oxalhydrazide shows the greatest tendency to formation of complex salts. This increase in tendency to form complex salts caused by the increase in supplementary valencies due to the nitrogen atoms accords well with the views of Ley (A., 1905, i, 175) as to the structure of such salts.

As criteria for the occurrence of internally complex salts were accepted an abnormal colour (usually intense), and stability towards alkali and acetic acid. The salts were prepared in each case in alkaline solution, and caused to crystallise by the addition of methyl alcohol.

Oxamic acid under the above conditions gave no complex salt with a nickel, iron, or manganese salt, but with copper acetate and concentrated potassium hydroxide solution, bluish-violet needles of a *potassium-copper* salt, $K_2(NH \cdot CO \cdot CO_2)_2Cu$, were obtained, which are decomposed by excessive alkali or by pure water, yielding copper oxide.

Oxamide gave no compound with iron or manganese, but yielded a *potassium-copper* salt, $K_2(NH \cdot CO \cdot CO \cdot NH)_2Cu,1\frac{1}{2}H_2O$, reddish-violet needles, soluble in alkali to a violet-blue solution, which slowly decomposes, and a *potassium-nickel* salt, $K_2(NH \cdot CO \cdot CO \cdot NH)_2Ni$, bright yellow plates soluble in dilute hydroxide solution to an unstable golden-yellow solution.

Oxalaminohydrazide yielded a *potassium copper* salt, violet-red needles, $K_2(NH \cdot NH \cdot CO \cdot CO \cdot NH)_2Cu,2H_2O$, which, when moist, undergoes gradual decomposition into a basic copper oxamate, and a *potassium-nickel* salt, $K_2(NH \cdot NH \cdot CO \cdot CO \cdot NH)_2Ni$, golden-yellow rods, which dissolve in water to a reddish-yellow solution without decomposition (compare Kerp and Unger, A., 1897, i, 270; Schiff, A., 1902, i, 85).

Oxalhydrazide in strong alkali solution with nickel acetate gives a violet solution, but on crystallisation yellow, hexagonal prisms of a more complex product are obtained; the *potassium-copper* salt,

$$K_2(N_2H_2 \cdot CO \cdot CO \cdot N_2H_2)_2Cu,$$
forms bright brown needles, decomp. 270°, soluble in water to a greenish-yellow colour.

Hydroxyloxamide gives a *sodium-copper* salt,

$$Na_4(NH \cdot CO \cdot CO \cdot NO)_2Cu, 4H_2O,$$

reddish-violet needles, and a *sodium-nickel* salt,

$$Na_4(NH \cdot CO \cdot CO \cdot NO)_2Ni, 2H_2O,$$

orange-yellow, hexagonal prisms, which decomposes about 280°. From the composition of these two salts the authors are of the opinion that the salts are derived by displacement of hydroxylic hydrogen, and that under the influence of the alkali used in the process of preparation the $-CO \cdot NH_2$ group undergoes a preceding change into the structure $-C(:NH)OH$. With bivalent and tervalent iron, also, hydroxyloxamide gives yellowish-red alkaline solutions.

Oxalodihydroxamic acid gives a *potassium-copper* salt,

$$K_2(C_4N_4O_8H_3)Cu,$$

brownish-red needles, which decompose at 180°, and a *potassium-nickel* salt, $K_2(C_4N_4O_8H_3)Ni, H_2O$, brownish-yellow needles. Cobalt and iron salts in the presence of excess of alkali give reddish-yellow solutions with oxalodihydroxamic acid.

Formaldoxime is known to give deep colorations with copper, iron, and nickel solutions in the presence of potassium hydroxide (compare Dunstan, T., 1898, **73**, 353), but complex salts have now been isolated for the first time. The colour of the solutions is so intense that manganese, iron, and nickel can be detected at a dilution of one part in a million; the solution of the manganous salt is yellow, but rapidly oxidises in the air to a *manganic* salt, $(CH_2:NO)_3Mn, 2H_2O$., blackish-brown, rectangular plates, which decompose above 220°, and give an intense reddish-brown solution in water. The almost colourless alkaline solution of the nickelous salt in a similar manner absorbs oxygen, yielding a deep brown solution of the *sodium-nickelic* salt,

$$Na_3(CH_2:NO)_6Ni,$$

steel-blue, lustrous crystals, which decompose near 225°. The volume of oxygen absorbed in the two previous oxidations was in good accord with the theoretical. In a similar manner the yellowish red alkaline solution of the ferrous salt undergoes gradual oxidation to the deep violet-red solution of the sodium-ferric salt, which is better obtained by using a ferric salt directly; the *sodium-ferric* salt,

$$Na_2(CH_2:NO)_5Fe, H_2O,$$

forms blue, hexagonal plates, which decompose near 195°. The structure of these salts is believed to be analogous to that of the internally complex salts of the dioximes.   D. F. T.

Synthesis of Parabanic and Substituted Parabanic Acids. HEINRICH BILTZ and ERNST TOPP (*Ber.*, 1913, **46**, 1387—1404).— The authors have effected the synthesis of parabanic and substituted parabanic acids by the action of oxalyl chloride on carbamide and substituted carbamides in ethereal or, more rarely, acetic anhydride solution. Reaction generally takes place smoothly, and the yields, particularly with doubly-substituted carbamides, are excellent. In the case of parabanic acid itself, and, possibly, of dimethylparabanic acid, however, the older methods are simpler and cheaper.

Parabanic acid was obtained in small yield by the action of a boiling ethereal solution of oxalyl chloride on carbamide, and was identified

by conversion into its silver salt. Oxalyldicarbamide, $C_4H_6O_4N_4$, m. p. 270—275° (decomp.), was isolated as by-product. Similar observations have been made by Bornwater (A., 1911, i, 617). Methylparabanic acid, m. p. 153—154°, b. p. 201—202°/13 mm., and oxalyldimethylcarbamide, m. p. 230—232° (decomp.), were similarly prepared from methylcarbamide. An attempt to prepare oxalyl-dimethylcarbamide by melting methylparabanic acid with methyl-carbamide was unsuccessful. Boiling acetic anhydride converted methylparabanic acid into 3-acetyl-1-methylparabanic acid, m. p. 183—185°, which was also obtained by the action of oxalyl chloride on acetylmethylcarbamide. Cold aqueous hydrochloric acid was without action on it, whilst the hot reagent caused great decomposition. Saturation of an absolute alcoholic suspension of it with hydrogen chloride brought about the elimination of the acetyl group, methylparabanic acid being formed in almost quantitative yield.

Dimethylparabanic acid, leaflets, m. p. 154°, b. p. 148—150°/13 mm., was obtained in 70% yield from s-dimethylcarbamide and oxalyl chloride, and also from s-dimethylcarbamide and ethyl chloropyruvate.

Dimethylcarbamide hydrochloride, needles, m. p. 124°, was obtained by saturating a solution of s-dimethylcarbamide in ethyl acetate with hydrogen chloride. *Methylcarbamide hydrochloride*, prepared similarly, is very hygroscopic. It has m. p. about 85—87° after softening at about 70°, and evolves hydrogen chloride at about 125°.

Ethylparabanic acid, m. p. 127—128°, and *oxalyldiethylcarbamide*, needles, m. p. 220—222° (decomp.), were obtained from ethylcarbamide and oxalyl chloride. The properties of the first-named substance differ from those of the ethylparabanic acid described by Andreasch (A., 1898, i, 243).

9-Ethyluric acid glycol (A., 1910, i, 526) was oxidised by potassium dichromate and sulphuric acid to ethylparabanic acid. An attempt was also made to degrade the former substance to the latter in the manner adopted for 7 : 9-dimethyluric acid (Biltz and Krebs, A., 1910, i, 521). An aqueous solution of the glycol was converted by heat into 5-*hydroxy* - 3 - *ethylhydantoylcarbamide*, which was transformed into *3-ethylcaffolide* and ammonium chloride when treated with hydrochloric acid and subsequently evaporated to dryness. When an aqueous solution of 3-ethylcaffolide was boiled, 5-*hydroxy*-3-*ethylhydantoylamide* was formed, which, when oxidised, yielded ethylparabanic acid. The intermediate products could not be obtained in the crystalline state, but the course of the degradation can be deduced from the final product and from the isolation of the by-products expected in the various stages.

Diethylparabanic acid, needles, m. p. 49—51°, b. p. 138—140°/13 mm., was obtained in 78% yield from s diethylcarbamide and oxalyl chloride, and was identical with the product obtained by the degradation of 7 : 9-diethyluric acid glycol (A., 1911, i, 693). Diethylthioparabanic acid had b. p. 148—150°/13 mm.

Phenylparabanic acid, m. p. 213—214° after softening at 208° [Stojentin (A., 1885, 1196) gives m. p. 208°], diphenylparabanic acid, m. p. 202° after previous softening, *benzylparabanic acid*, m. p.,

167—169°, and pp-*bisbromophenylparabanic acid*, $C_{15}H_8O_5N_2Br_2$, were prepared in an analogous manner.

Thiocarbamide reacted vigorously with oxalyl chloride at first, but, even in the presence of a considerable excess of the latter, was not completely converted into *thioparabanic acid*. By repeated crystallisation from ethyl acetate, the latter was obtained in yellowish-red, indistinct crystals, m. p. 215—220° (decomp.), and was further identified by conversion into the *silver* salt, $C_3O_2N_2SAg_2$, and transformation of the latter into 1 : 3-dimethylthioparabanic acid, m. p. 113—115° [Andreasch (A., 1881, 897) gives 112·5°], by means of methyl iodide. When desulphurised by means of hydrochloric or nitric acids, this substance yielded dimethylparabanic acid. Dimethylthioparabanic acid was also prepared by the action of oxalyl chloride on dimethylthiocarbamide, and then had m. p. 113—115°, after softening at 110°, b. p. 153—155°/13 mm.

The authors have also examined the "thioparabanic acid" obtained by Michael (A., 1894, i, 164) by the condensation of thiocarbamide with ethyl oxalate in the presence of sodium ethoxide. They find that it softens at 165°, and has m. p. 173—175° (decomp.). The fusion separates into two layers, the upper one of which begins to distil at about 190°. Since also this substance slowly yields a precipitate with calcium chloride and ammonia, even at the ordinary temperature, the authors are led to the conclusion that it is an additive compound of thiocarbamide and ethyl oxalate (compare Nencki, A., 1874, 981).

Ethylthioparabanic acid was obtained in small yield from ethylthiocarbamide and oxalyl chloride, the loss being chiefly attributable to the difficulty of separating the acid from unchanged ethylthiocarbamide by crystallisation. The observed m. p., 65—69°, is sufficiently close to that found by Andreasch (66°, *loc. cit.*) to prove the identity of the two products. Desulphurisation by means of a boiling alcoholic solution of silver nitrate converted ethylthioparabanic acid into ethylparabanic acid, m. p. 127—128°.

Diphenylthioparabanic acid, pale yellow needles, m. p. 228—230°, was obtained in 94% yield from s-diphenylcarbamide and ethereal oxalyl chloride.   H. W.

Oxalyldicarbamide. HEINRICH BILTZ and ERNST TOPP (*Ber.*, 1913, 46, 1404—1417. Compare preceding abstract, and also Bornwater, A., 1911, i, 617).—When an ethereal solution of oxalyl chloride reacts with finely-powdered carbamide, parabanic acid is formed together with a substance characterised by its very sparing solubility in ordinary solvents, to which the constitution $C_2O_2(NH \cdot CO \cdot NH_2)_2$ is ascribed. This latter substance differs from the oxalyldicarbamide prepared by Grimaux by the fusion of a mixture of parabanic acid and carbamide (A., 1880, 105) in that it gives no biuret reaction, whereas Grimaux's compound yields a faint violet coloration with potassium hydroxide and copper sulphate. Further, oxalyldicarbamide may also be obtained by the oxidation of allantoin in acid solution, 5-hydroxyallantoin being formed as an intermediate product :

$$CO\begin{subarray}{l} \diagup NH \cdot C(OH) \cdot NH \cdot CO \cdot NH_2 \\ \diagdown NH \cdot CO \end{subarray} \longrightarrow C_2O_2(NH \cdot CO \cdot NH_2)_2.$$
The authors have made a comparative critical examination of these three products, and are led to the conclusion that they are probably identical. The coloration given by Grimaux's compound with potassium hydroxide and copper sulphate is probably due to the presence of some impurity, the nature of which could not be established, but which is neither biuret, oxamide, allantoxanic acid nor allantoxaidine. Certain differences, however, remain unexplained. Thus, oxalyldicarbamide, when acted on by hydriodic acid, yields hydantoin together with other products, whilst, in similar circumstances, Grimaux's compound gives a *substance*, $C_4H_5O_3N_3$, in small quantity. Also, potassium hydroxide transforms all three compounds mainly into oxaluric acid and oxalic acid, but differences are found among the by-products of the action.

Ponomarev's observation (A., 1885, 760) that concentrated potassium hydroxide converts Grimaux's compound into potassium allantoxanate is probably incorrect.

Oxalyldicarbamide was obtained by the oxidation of an aqueous solution of allantoin and sodium acetate by means of ammonium persulphate or by potassium permanganate in dilute acetic acid solution. A portion of the allantoin remained unattacked even when an excess of the oxidising agent was used, whilst, also, oxaluric acid was formed. The latter was isolated in the form of its *ammonium* salt, needles, decomposing at 243—245°, from which the free acid and also the silver salt were obtained.

Grimaux's compound was obtained by heating a mixture of parabanic acid and carbamide and purified by extraction with boiling water. Such preparations yielded with potassium hydroxide and copper sulphate violet colorations of varying intensity. By repeated solution of the product in concentrated sulphuric acid, re-precipitation by means of water, and subsequent repeated extraction with boiling water, substances were obtained which gave only a very faint violet coloration, but the impurity could not thus be completely removed.

All three preparations evolved ammonia at the ordinary temperature when treated with potassium hydroxide (D 1·1—1·4). Under similar conditions oxalyldimethylcarbamide evolved only methylamine, whilst oxalyldiethylcarbamide gave ethylamine. These substances must therefore have the formulæ $C_2O_2(NH \cdot CO \cdot NHMe)_2$ and $C_2O_2(NH \cdot CO \cdot NHEt)_2$ respectively.

When treated with potassium hydroxide under varying conditions, neither of the compounds yielded potassium allantoxanate. Specimens of oxalyldicarbamide, prepared from oxalyl chloride or from allantoin, yielded carbon dioxide, potassium oxalate, and potassium oxalurate. Grimaux's compound yielded mainly potassium oxalurate; sometimes, also, a potassium salt which crystallised in short prisms, became somewhat discoloured at 280°, but was not greatly decomposed at 360°. This salt was probably derived from the impurity which yields the violet coloration, since it gave a distinct violet colour with potassium hydroxide and copper sulphate. In one experiment a second potassium salt, prisms, was obtained, which, with hydrochloric acid, yielded the free acid. The latter was sparingly soluble in water, darkened from 275° onwards, but showed no decomposition point below 360°.

The three compounds were very stable towards acid, and no differences were observed in their behaviour in this respect. Oxalic acid, but no parabanic acid, was obtained from each by the action of boiling fuming nitric acid. Concentrated hydriodic acid (D 1·5) converted Grimaux's compound into oxalic acid. The formation of methyl- and ethyl-parabanic acids by the action of boiling glacial acetic acid on dimethyl- and diethyl-oxalyldicarbamide (compare previous abstract) must be attributed to the formation of the glyoxalone ring during the course of the action, since oxaluric acid itself is partly transformed into parabanic acid by prolonged treatment with boiling glacial acetic acid.

Hydantoin, m. p. 215—217°, and ammonium iodide were obtained by the action of fuming hydriodic acid (D 1·96) at 130—140° on oxalyldicarbamide obtained from oxalyl chloride or from allantoin. Under similar treatment, Grimaux's compound yielded a substance, $C_4H_5O_3N_3$, leaflets, m. p. 270—273° (decomp.), which behaved as a monobasic acid. The *ammonium* salt formed needles, which decomposed at 270—273°. The *silver* salt, $C_4H_4O_3N_3Ag$, was analysed, and appeared to contain a certain amount of silver united to nitrogen.

H. W.

Oxalyl Chloride. V. Oxalyl Bromide and Attempts to Prepare Dicarbon Dioxide. HERMANN STAUDINGER and E. ANTHES (*Ber.*, 1913, **46**, 1426—1437. Compare A., 1912, i, 567).—The authors have prepared oxalyl bromide, which they find to be more readily decomposed by heat and more reactive than the corresponding chloride. In the hope of isolating dicarbon dioxide, CO:CO, they have investigated the action of metals on it. Ready interaction occurs with both zinc and mercury, but in each case carbon monoxide is evolved, so that dicarbon dioxide is probably incapable of existence at the ordinary temperature. With potassium, or the liquid alloy of sodium and potassium, an explosive product is formed, to which the authors attribute the composition OK·C:C·OK.

Phosphorus pentabromide (2 mols.) reacts slowly with anhydrous oxalic acid (1 mol.). If the mixture is warmed, oxalyl bromide is not obtained, nor is the process improved by mixing the materials with sand. If, however, phosphoryl bromide is mixed with phosphorus pentabromide, the dried oxalic acid added, and the mixture maintained at 50° during one day and subsequently distilled, small quantities of oxalyl bromide are obtained. A better method consists in the treatment of well-cooled oxalyl chloride with hydrogen bromide (compare this vol., i, 616), when oxalyl bromide is obtained in 85% yield. It is a greenish-yellow liquid, b. p. 102—103°/720 mm., 16—17°/10 mm., m. p. −19·5°.

A boiling 20% ethereal solution of oxalyl chloride does not react with zinc even after addition of iodine, mercuric chloride, or a trace of water. In ethyl acetate solution, reaction occurs if the zinc has been activated by means of diphenylchloroacetyl chloride. Carbon monoxide is then formed. Mercury, sodium, silver, or magnesium turnings do not react with oxalyl chloride, but a brown precipitate is obtained with magnesium powder in the presence of ether, investigation of

which is incomplete. The vapour of oxalyl chloride is practically completely decomposed by silver at 200°, carbon monoxide being formed. With zinc practically no action occurs.

Oxalyl bromide, on the other hand, is readily decomposed by zinc or mercury at the ordinary temperature, carbon monoxide being formed. Mercurous bromide has no action on it at the ordinary temperature or at 100°. Sodium potassium amalgam reacts with oxalyl bromide without marked development of heat or alteration in appearance. The product, however, explodes violently when subjected to vibration. Attempts to cause potassium to react with oxalyl bromide vapour at 130° or in xylene solution were unsuccessful.

Oxalyl bromide gradually becomes pale reddish-brown when preserved, owing to separation of bromine, decomposition being catalysed by light. At 100° it is stable, but at 150—200° is decomposed into carbon monoxide, bromine, and carbonyl bromide. Oxalyl chloride, on the other hand, could be heated during eighteen hours at 200° without noticeable decomposition occurring; at 340° it is completely decomposed during seventy hours into carbon monoxide and carbonyl chloride.

Oxalyl bromide reacts readily with benzaldehyde in light petroleum solution, forming a white additive *product*, m. p. 131°, with decomposition into benzaldehyde, benzylidene bromide, and carbon monoxide. Under similar conditions an additive *product* is slowly formed from oxalyl chloride, which, when rapidly heated, has m. p. about 212°, but loses carbon monoxide at a lower temperature.

Oxalyl bromide reacts more readily than the corresponding chloride with dimethylaniline, dimethylaminobenzoic acid, crystal-violet and tetramethyldiaminobenzil being formed.

Oxalyl iodide could not be isolated by the action of hydrogen iodide on oxalyl chloride. Even at − 80° only carbon monoxide and iodine were obtained. The latter substances were also produced quantitatively when a solution of oxalyl chloride in ethyl acetate was boiled with sodium iodide.

Unsuccessful attempts were also made to obtain diphenyloxaliminobromide and iodide by the action of the requisite halogen acid on diphenyloxalimino-chloride, $NPh:CCl\cdot CCl:NPh$. The bromide could not be obtained from oxanilide by the action of phosphorus tri- or pentabromide.　　　　　　　　　　　　　　　　　H. W.

An Ester of Hydrocobalticyanic Acid. CHARLES E. BOLSER and L. B. RICHARDSON (*J. Amer. Chem. Soc.*, 1913, **35**, 377—381).— By the action of ethyl iodide on silver cobalticyanide, suspended in alcohol, *ethyl dihydrogen cobalticyanide*, $EtH_2Co(CN)_6, H_2O$, has been obtained as a yellowish-white solid which loses its water of crystallisation at a little over 100° and becomes blue. On the addition of silver nitrate to a solution of the ester, *disilver ethyl cobalticyanide* is produced as a white precipitate; a *copper* salt was also obtained. When the ester is treated with sodium hydroxide, ethylcarbimide is evolved, indicating that the 'ethyl group in some, if not all, of the molecules is attached to nitrogen.

An attempt was made to prepare the corresponding ester of hydroferricyanic acid, but without success.   E. G.

Reaction of Nitroprussides with Acetone. LIVIO CAMBI (*Atti R. Accad. Lincei*, 1913, [v], 22, i, 376—381).—In this reaction the production of the coloration is accompanied by the production of oximinoacetone, for it is possible to isolate in impure form a coloured salt which yields this compound on treatment with alkali. Analogous results were obtained in the case of acetophenone, a coloured salt being obtained which yielded oximinoacetophenone when treated with alkali.   R. V. S.

Maximum Yield of Amines by the Reduction of Alkyl Cyanides. JITENDRA NATH RAKSHIT (*J. Amer. Chem. Soc.*, 1913, 35, 444—446).—A study of the conditions under which amines are produced by the reduction of nitriles has shown that the best yields can be obtained by the following modification of Ladenburg's method.

The nitrile (5 c.c.) is dissolved in 75 c.c. of alcohol and the solution is introduced in successive quantities of 5 c.c. into a flask containing 5 grams of sodium and attached to a reflux condenser. The mixture is heated at 50—60°. After 20 c.c. of the solution have entered the flask, 5 c.c. of alcohol are added, and the amine evolved on distillation is absorbed in dilute hydrochloric acid. When the whole of the nitrile solution has been introduced, alcohol is added until a layer remains above the solid sodium ethoxide in the flask. When the evolution of hydrogen ceases, the condenser is removed and the flask is connected directly to the absorption apparatus and heated as long as alkaline vapour is produced. If necessary, a further quantity of alcohol is added and the distillation continued. The acid solution is evaporated to dryness on the water-bath, and the amine hydrochloride extracted from the residue with a mixture of alcohol (15 c.c.) and ether (10 c.c.).

The results of experiments with acetonitrile, propionitrile, and butyronitrile show that the amines can be obtained by this method in nearly quantitative yield.   E. G.

Amylene-*iso*nitroamineoxime and **-bisnitroso*iso*nitroamine.** GUIDO CUSMANO (*Atti R. Accad. Lincei*, 1913, [v], 22, i, 225—231. Compare A., 1911, i, 186).—Cryoscopic molecular weight determinations on the β-nitrosohydroxylamino-β-methylbutan-γ-oneoxime previously described, and on its sodium salt indicate that the compound is probably a bisnitroso*iso*nitroamine. Its formation is probably preceded, however, by that of an *iso*nitroamineoxime which suffers rearrangement and polymerisation. In fact, the freshly prepared substance has m. p. 71°; later, or after recrystallisation, the m. p. is 82°, as formerly stated. Hence it is possible to proceed from oximes of the type $:CX \cdot C:N \cdot OH$ to nitrosyl compounds, $:CX \cdot CH \cdot NO$.

When the bisnitroso*iso*nitroamine is treated with sodium nitrite in aqueous solution, the bisnitroso-oxime, $(NO \cdot CMe_2 \cdot CMe:NOH)_2$, is

formed; the crystals at first melt at 83°, but later on, or after recrystallisation, the m. p. is 140°; the substance is soluble in alkali hydroxides and in acids, and gives a blue coloration with diphenylamine and sulphuric acid.

The *iso*nitroamineoxime previously described yields an *ethyl* ester, $C_7H_{15}O_2N_8$, m. p. 119°, which is prepared by means of the *silver* salt.

The *isonitroamine* of β-methylbutan γ-one, $CMe_2(N_2O_2H)\cdot COMe$, is obtained by the action of hydrochloric acid on the sodium salt of the *iso*nitroamineoxime, or by the action of nitrous acid on β-hydroxylamino-β-methylbutan-γ-one (previously described); it forms large, tabular crystals, m. p. 62°, and gives a blue coloration with diphenylamine and sulphuric acid. The substance has acid properties and is fairly stable, but when heated above its m. p. decomposes, leaving a partially crystalline residue, from which a substance crystallising in quadrangular tablets, m. p. 99°, can be isolated.   R. V. S.

Preparation of Fatty Acids and their Salts containing Arsenic and Phosphorus. FELIX HEINDMANN (D.R.-P. 257641).— When the unsaturated acids of the acetylene series are heated with the halogen derivatives of arsenic or phosphorus, they furnish acidic compounds having a high molecular weight and containing a halogen substituent in addition to phosphorus (or arsenic); they give rise to soluble alkali, and insoluble calcium and strontium salts.

The *compound* produced when stearolic acid and arsenic trichloride (1·5 parts) are heated together at 140° during six hours is obtained (by extraction with ether) as a viscous oil which gradually in part solidifies; it contains As = 11% and chlorine 6—7%; the *strontium* salt, a flesh-coloured powder, contains 12% As; the *calcium* salt is also mentioned.

The *compound* from behenolic acid and arsenic trichloride is a pale brown, viscous oil containing 8—9% As and 5—6% Cl; the *strontium* salt is a colourless powder.

When stearolic acid is heated with an equal quantity of phosphorus trichloride at 140° during fifteen hours, it furnishes two acidic *compounds*; one a viscous, brownish-yellow acid extractable with ether containing P = 4—5% and Cl = 8%; the other an orange-yellow resin insoluble in ether and containing P = 15%. The analogous *compound* from behenolic acid and phosphorus trichloride, and the *strontium* and *calcium* salts are also described, whilst the arsenic and phosphorus chlorides employed can be replaced by the corresponding bromides.   F. M. G. M.

The Benzene Problem. HANS VON LIEBIG (*J. pr. Chem.*, 1913, [ii], **87**, 393—397. Compare A., 1912, i, 686).—A reply to Gebhard's criticism (this vol., i, 28).   F. B.

3 : 3-Dimethyl-[0,1,3]-*dicyclo*hexane. Its Synthesis and Behaviour on Catalytic Reduction. NICOLAI D. ZELINSKI and A. E. USPENSKI (*Ber.*, 1913, **46**, 1466—1474).—The starting point for this substance was 1 : 1-dimethyl*cyclo*hexane-3 : 5-dione, which was prepared by a slight modification of the process of Vorländer (A.,

1897, i, 275); this substance is reduced by the gradual addition of sodium to a hot solution in absolute alcohol with the formation of 1 : 1-*dimethyl*cyclohexane-3 : 5-*diol*, a sweet substance which separates from a mixtuie of benzene and acetone in lustrous, colourless needles. By heating with phosphorus tribromide in a sealed tube at 110—120°, this glycol is converted into 3 : 5-*dibromo*-1 : 1-*dimethyl*cyclohexane, a colourless liquid, b. p. 120—122°/12 mm., D_4^{18} 1·5865, n^{18} 1·5329, which can also be obtained, but less advantageously, by the action of hydrobromic acid on the glycol. Zinc dust acts readily on a warm aqueous-alcoholic solution of this dibromide with the formation of a second ring, the product being 3 : 3-*dimethyl*-[0,1,3]-bicyclo*hexane*,

$$CH_2 {\Large<}{\genfrac{}{}{0pt}{}{CH-CH_2}{CH-CH_2}}{\Large>}CMe_2.$$
This substance is a colourless liquid, b. p. 115° (corr.), D_4^{20} 0·7962, n^{20} 1·4331, which reacts vigorously with dry bromine, but only slightly with sulphuric acid diluted with half its bulk of water or also with cold dilute potassium permanganate solution. The formation of hydrogen bromide in the first reaction and the lack of change with the other reagents indicate the saturated nature of the hydrocarbon ; in fact, treatment with potassium permanganate solution was resorted to as a means of removing small quantities of an olefinic cyclic hydrocarbon impurity. For the purpose of comparison, the isomeric 1 : 1-dimethyl-Δ^3-*cyclo*hexene (Crossley and Renouf, T., 1905, 87, 1491) was examined, and the following values obtained : b. p. 117—117·5° (corr.), D_4^{20} 0·7994, n^{20} 1·4430, the differences in the density and refractivity indicating the more saturated nature of the new substance.

When 3 : 3-dimethyl-[0,1,3]-*di*cyclohexane is heated with hydriodic acid at 100—110°, an iodo-compound is obtained, which can be reduced in alcoholic solution by zinc dust, yielding a hydrocarbon which from its properties, b. p. 115—116°/760 mm., D_4^{20} 0·7703, n^{20} 1·4223, and its indifference towards permanganate and bromine is probably 1 : 1 : 3-*trimethyl*cyclopentane. That the fission of the trimethylene ring has occurred thus and not at the 2 : 6 linking is evidenced by the distinct nature of the otherwise expected *gem*-dimethylhexamethylene (Crossley, *loc. cit.*). Reduction by hydrogen under the catalytic influence of platinum-black at 125°, or by palladium-black at 55—60°, followed a quite different course, the product, b. p. 109·5—110·5° (corr.), D_4^{20} 0·7403, n^{20} 1·4088, being probably 1-*methyl*-2-*iso*butyl*cyclo*propane. As might be expected (Zelinski, A., 1913, i, 254), reduction by hydrogen under the influence of nickel causes a more considerable change, and even with reduction at 95—100° the physical properties of the product indicate the admixture of the above *cyclo*propane derivative with an appreciable quantity of an octane.   D. F. T.

Anhydrides of Aromatic Sulphonic Acids. HANS MEYER and KARL SCHLEGL (*Monatsh.*, 1913, 34, 561—577).—The action of thionyl chloride on aromatic sulphonic acids presents another example of the very considerable effect of minute traces of foreign substances

on the course and products of a chemical change. The product may be, in this case, the sulphonic anhydride, the sulphonyl chloride, or a mixture of both; the variation is apparently due to traces of impurity in the thionyl chloride, but in the majority of cases investigated no trustworthy decision could be made as to the disturbing factor. The formation of chloride and anhydride appears to be concurrent.

The sulphonic acid anhydrides are colourless or pale yellow, crystalline solids, which are remarkably stable towards water and weak alkali. They react with alcohol, ammonia, and amines, producing the corresponding esters and amides; they can be sulphonated and nitrated. On account of their sparing solubility in indifferent organic solvents they can easily be separated from the very soluble acid chlorides. It is surprising that, although they are stable towards water in bulk, yet they become easily hydrated by moist solvents or by exposure to damp air. The thionyl chloride used for their preparation was purified by distillation over quinoline or dimethylaniline (compare Besthorn, A., 1909, i, 673), the remaining yellow coloration being removed by further successive distillations over linseed oil and pure bees-wax.

Benzenesulphonic acid when heated with excess of thionyl chloride passes into solution with loss of its water of crystallisation, and after further heating, the solution, when cooled, deposits a mixture of benzenesulphonyl chloride with the anhydride, m. p. 90—91° (Billeter, A., 1905, i, 584); the latter substance was usually the preponderating constituent, but occasionally, with apparently the same conditions, the case was the reverse. Silver benzenesulphonate reacts with thionyl chloride yielding the acid chloride as the sole product.

p-*Bromobenzenesulphonic anhydride*, obtained by heating the acid with thionyl chloride and pouring the reaction mixture into ice water, is a colourless, crystalline substance, m. p. 164—167° (decomp.).

2 : 5-*Dibromobenzenesulphonic anhydride*, obtained by a similar process to the last, is a crystalline powder (compare Rosenberg, A., 1886, 551).

m-*Nitrobenzenesulphonic anhydride*, obtained analogously, forms colourless crystals decomposing at 130—140°; the accompanying *chloride* had m. p. 58°.

p-*Toluenesulphonic anhydride*, crystals, m. p. 122—125°, is obtained together with the chloride by heating p-toluenesulphonic acid with pure thionyl chloride; if the thionyl chloride is not pure, the acid chloride is the sole product.

Mesitylensulphonic anhydride is often obtained mixed with the corresponding chloride if mesitylenesulphonic acid is heated with commercial specimens of thionyl chloride. If the last substance has been purified the only product is the acid chloride, but the power to produce the anhydride is restored to the thionyl chloride by distilling it with sulphur chloride. Sodium mesitylenesulphonate behaves in the same curious manner with the various specimens of thionyl chloride.

ψ-*Cumenesulphonic anhydride* is obtained mixed with the corre-

sponding acid chloride under the reverse conditions to those observed in the last case. Purified thionyl chloride gives rise to a mixture of the acid anhydride and acid chloride, whilst the commercial substance yields the acid chloride only.

α-Naphthalenesulphonic anhydride could not be obtained as the corresponding acid and also the sodium salt of the acid were converted by thionyl chloride entirely into the acid chloride.

β-Naphthalenesulphonic anhydride, a pale yellow, crystalline substance, is obtained together with the *chloride*, m. p. 73—74°, by the interaction of β-naphthalenesulphonic acid and excess of thionyl chloride.

α-Anthraquinonesulphonic acid, yellow crystals, m. p. 210—211°, and also the β-isomeride are converted by thionyl chloride entirely into α- and β-anthraquinonesulphonyl chlorides, crystalline solids, m. p. 203—204° and 185—187° respectively.

2-Chloro-5-nitrobenzenesulphonic anhydride forms colourless crystals, m. p. 120—125° (decomp.).

Ethanesulphonic acid with thionyl chloride yielded the acid chloride, whilst 3-pyridinesulphonic acid failed to react.   D. F. T.

Tridiphenylylmethyl. WILHELM SCHLENK (*Ber.*, 1913, **46**, 1475—1481. Compare A., 1910, i, 236).—In reply to Schmidlin (this vol., i, 32) it is stated that the tridiphenylylmethyl obtained earlier by the author (*loc. cit.*) is a homogeneous product, and that the supposed isomeride of Schmidlin is due to an impurity caused by the presence of 4:4'-dibromodiphenyl in the *p*-bromodiphenyl used. In the subsequent Grignard reaction by which the carbinol is produced, the former substance gives rise to 4:4'-*diphenylene-bis-[bidiphenylylcarbinol]*, $OH \cdot C(C_6H_4Ph)_2 \cdot C_6H_4 \cdot C_6H_4 \cdot C(C_6H_4Ph)_2 \cdot OH$, which, mixed with tridiphenylylcarbinol, constitutes Schmidlin's "β-tridiphenylylcarbinol."

4:4'-Diphenylene-bis-[-bidiphenylylcarbinol] can be obtained pure by the condensation of 4:4'-di-iododiphenyl with bisdiphenylylketone and also of ethyl diphenyl-4:4'-dicarboxylate with iododiphenyl, in each case by the Grignard process. The substance is being more closely investigated.   D. F. T.

α-Naphthylbisdiphenylylmethyl. WILHELM SCHLENK and C. BORNHARDT (*Ber.*, 1913, **46**, 1482—1483).—Contrary to the opinion of Schmidlin and Bergmann (this vol., i, 46), *α-naphthylbisdiphenylylcarbinol*, $C_{10}H_7 \cdot C(C_6H_4Ph)_2 \cdot OH$, can be readily obtained by the action of magnesium α-naphthyl bromide on bisdiphenylyl ketone; it forms prismatic crystals, m. p. 228°, which give a bluish-violet solution in sulphuric acid. When heated with a mixture of acetyl chloride and benzene, it is converted into *chloro-α-naphthylbisdiphenylylmethane*, $C_{10}H_7 \cdot C(C_6H_4Ph)_2Cl$, m. p. 214—216°, which gives a deep blue solution in molten phenol. If the chloro-compound is heated in benzene solution with copper bronze under an atmosphere of carbon dioxide, *α-naphthylbisdiphenylylmethyl* is obtained, which separates from its brownish-red benzene solution as a greyish-green, crystalline powder. As a

solution of this substance which has been converted into the peroxide by shaking with air does not regain any of its original colour on keeping, it is probable that the substance is almost entirely unimolecular. D. F. T.

Preparation of Aromatic Nitroamino-compounds. HEINRICH BART (D.R.-P. 258059).—When 3-nitro-4-hydroxyazobenzene-4'-sulphonic acid, $OH \cdot C_6H_3(NO_2) \cdot N \vdots N \cdot C_6H_4 \cdot SO_3H$, is reduced with iodine and sulphurous acid (or phosphorus) it furnishes sulphanilic acid and 3-*nitro*-p-*aminophenol*, glistening. red needles, m. p. 127°, whilst 3-nitro-*p*-aminophenol, together with 4-chloroaniline-3-sulphonic acid, is obtained in a similar manner from 3-nitro-4-hydroxy-4'-chloroazo-benzene-3'-sulphonic acid, $OH \cdot C_6H_3(NO_2) \cdot N \vdots N \cdot C_6H_3 \cdot Cl \cdot SO_3H$.

F. M. G. M.

Preparation of 5-Chloro-6 amino-1-naphthol-3-sulphonic Acid. FARBENFABRIKEN VORM. FRIEDR. BAYER & Co. (D.R.-P. 258299).—When β-naphthylamine-5 : 7-disulphonic acid is treated with *p*-toluenesulphonyl chloride and the product subsequently chlorinated, it gives rise to 1-*chloro-2-p-toluenesulphonylaminonaphthalene*-5 : 7-*disulphonic acid*, a pale yellow, crystalline powder ; when this is fused at 150—180° with potassium hydroxide, it furnishes 5-*chloro*-6-*p*-*toluenesulphonylamino*-1-*naphthol*-3-*sulphonic acid*, a red, crystalline powder, which when stirred into fuming sulphuric acid yields 5-*chloro*-6-*amino*-1-*naphthol*-3-*sulphonic acid*. F. M. G. M.

Preparation of Creosol (*p*-Hydroxytolyl 3-Methyl Ether). SACCHARIN-FABRIK AKTIENGESELLSCHAFT VORM. FAHLBERG, LIST & Co. (D.R.-P. 258105. Compare A., 1877, ii, 888 ; 1899, i, 346).—When homocatechol is treated with methyl sulphate, it furnishes a 70% yield of pure creosol together with 5—6% of homoveratrole.

F. M. G. M.

Desmotropy of Phenols in the Anthracene Series. ROLAND SCHOLL (*Ber.*, 1913, **46**, 1442).—A claim for priority against Meyer and Schlösser (this vol., i, 295). H. W.

Certain *p*-Toluoylmethyl-, Phenyl-, Nitrophenyl-, Tolyl- and Naphthyl-ethers ; 3-*p*-Tolyl-1 : 4-benzoxazine and 3-*p*-Tolyl-phenmorpholine and their Derivatives. FRANZ KUNCKELL [with KARL PULS] (*Ber. Deut. pharm. Ges.*, 1913, **23**, 269—278).—A series of ethers has been prepared by the action of *p*-tolyl chloromethyl ketone, $C_6H_4Me \cdot CO \cdot CH_2Cl$, on the sodium or potassium salts of phenols.

Phenyl-p-*toluoylmethyl ether*, $C_6H_4Me \cdot CO \cdot CH_2 \cdot OPh$, white needles, m. p. 73—75°, is prepared by boiling an alcoholic solution of *p*-tolyl chloromethyl ketone with an aqueous solution of potassium phenoxide. When dissolved in alcohol and treated with an excess of bromine water, it yields a monobromo-*derivative*, $C_{15}H_{13}O_2Br$, needles, m. p. 105—107°. The similarly prepared p-*nitrophenyl* p-*toluoylmethyl ether* forms pale yellow leaflets, m. p. 165—166°, and is transformed by

phenylhydrazine in acetic acid solution into a somewhat unstable *phenylhydrazone*, yellow needles, m. p. 167—168°.   o-*Nitrophenyl* p-*toluoylmethyl ether* is best obtained by heating an intimate mixture of dry potassium o-nitrophenoxide with p-tolyl chloromethyl ketone at 70°, and crystallises in yellowish-white needles, m. p. 123—124°. p-*Chlorophenyl* p-*toluoylmethyl ether* forms a white, crystalline powder, m. p. 123—124°.   Phenyl p-toluoylmethyl sulphide, m. p. 64°, is obtained by heating a mixture of sodium phenyl sulphide and p-tolyl chloromethyl ketone with light petroleum at 80° during several hours. m-*Tolyl* p-*toluoylmethyl ether*, white leaflets, m. p. 72°, and p-*tolyl* p-*toluoylmethyl ether*, needles, m. p. 101—102°, are similarly prepared.   o-*Tolyl* p-*toluoylmethyl ether*, needles, has m. p. 82°. p-*Toluoylmethyl* β-*naphthyl ether*, prepared by boiling an alcoholic solution of p-tolyl chloromethyl ketone with a solution of β-naphthol in aqueous potassium hydroxide, forms colourless, rhombic crystals, m. p. 82—83°.   The similarly obtained p-*toluoylmethyl* a-*naphthyl ether*, m. p. 99—101°, yields with bromine in acetic acid solution a *compound*, $C_{19}H_{15}O_2Br$, silky needles, m. p. 148—150°.
3-p-*Tolyl* 1 : 4-*benzoxazine* (formula I.), m. p. 90—92°, is obtained by the reduction of a cold alcoholic solution of o-nitrophenyl p-toluoylmethyl ether by stannous chloride and fuming hydrochloric acid.   Its *hydrochloride* was analysed.   When the same ether is reduced at a higher temperature by tin and hydrochloric acid, 3-p-*tolylphenmorpholine* (formula II.) is formed in white needles, m. p. 67—68°.   It yields a *nitroso-*derivative, m. p. 101—102°.   The *hydrochloride*, needles, m. p. 190—191°, and the *platinichloride*, m. p. 180—182°, were analysed.

II. W.

Syntheses in the Fatty Aromatic Series. IX.   JULIUS VON BRAUN, A. GRABOWSKI, and G. KIRSCHBAUM (*Ber.*, 1913, 46, 1266—1282.   Compare A., 1912, i, 265 ; 1911, i, 830).—A systematic investigation of the effect of alterations in structure on the odour of the primary alcohols and aldehydes of the phenylethane and phenylpropane groups.   It is found that the introduction of a methyl radicle into the benzene ring has very little effect, but that such substitution at the carbon atom adjacent to the carbinol or aldehyde group of phenylpropyl alcohol or phenylpropaldehyde causes a characteristic change in the odour; substitution of a methyl radicle into the corresponding position of the phenylethane derivatives or at the carbon atom adjacent to the benzene ring in the phenylpropane derivatives produces only a slight weakening of the odour of the parent substances.

m-Xylyl bromide, $C_6H_4Me \cdot CH_2Br$, was converted through the cyanide into tolylethylamine, the benzoyl derivative of which when fused with phosphorus pentachloride and then distilled under reduced

pressure, undergoes decomposition into benzonitrile and m-*tolylethyl chloride*, a colourless liquid of pleasant odour, b. p. 112°/23 mm.; this on heating with sodium acetate and acetic acid for fifteen hours yields the corresponding *acetate*, a liquid of fruity odour, b. p. 130°/18 mm., which is easily hydrolysed to β-m-*tolylethyl alcohol*,

$$C_6H_4Me \cdot CH_2 \cdot CH_2 \cdot OH,$$
a liquid, b. p. 123—125°/18 mm., D_1^{20} 1·001, of a pleasant odour, resembling that of phenylethyl alcohol.

γ m-Tolylpropyl alcohol can be produced by a process similar to the last, but a more direct method is possible by starting with 6-methylquinoline or 8-methylquinoline; these can be reduced to the corresponding tetrahydroquinoline derivatives, which by the Schotten-Baumann reaction are converted into *benzoyl-6-methyltetrahydroquinoline*, m. p. 78°, and *benzoyl-8 methyltetrahydroquinoline*, needles, m. p. 100°, respectively. If these benzoyl compounds are caused to undergo scission by heating with phosphorus pentachloride (A., 1904, i, 918) they produce *benzo-o-γ-chloropropyl-p-toluidide*, m. p. 151°, and *benzo-o-γ-chloropropyl-o-toluidide*, m. p. 112°, which on cautious hydrolysis by hydrochloric acid in a sealed tube yield the hydrochlorides of o-γ-*chloropropyl-p-toluidine* (*hydrochloride*, m. p. 183°) and o-γ-*chloropropyl-o-toluidine* (*hydrochloride*, m. p. 172°; red *platinichloride*, m. p. 191°). Diazotisation of chloropropyl-p-toluidine hydrochloride, followed by treatment with copper powder, gives rise to 6-*chloro-3-methylphenylpropyl chloride*, $CH_2Cl \cdot [CH_2]_2 \cdot C_6H_3MeCl$, b. p. 125°/9 mm., possessing an odour resembling that of orange rind. If chloropropyl-p-toluidine is diazotised in solution in·sulphuric acid and the reaction product warmed, the resultant *chloropropyl-p-cresol* when heated with alkali loses hydrogen chloride with the formation of 6-*methylchroman*,

$$C_6H_3Me \underset{O——CH_2}{\overset{CH_2 \cdot CH_2}{<}}, \text{ a pale yellow liquid, b. p. } 107°/12 \text{ mm., of}$$
peppermint odour, which gives a red coloration with concentrated sulphuric acid. Reduction of a diazotised solution of the chloropropyltoluidine hydrochloride by an alkaline solution of stannous chloride produces m-*tolylpropyl chloride*, b. p. 130°/14 mm., which can be converted through the *acetate*, b. p. 136°/10 mm., into γ-m-*tolylpropyl alcohol*, $C_6H_4Me \cdot [CH_2]_2 \cdot CH_2 \cdot OH$, b. p. 140°/14 mm., D_1^{20} 0·9609, which closely resembles phenylpropyl alcohol in odour.

The most satisfactory starting point for γ-phenyl-n-butyl alcohol is acetophenone, which by condensation with zinc and ethyl bromoacetate followed by dehydration is converted into β-phenylcrotonic acid; this can be reduced to β-phenyl-n-butyric acid, the *ethyl* ester, b. p. 118°/9 mm., of which can be reduced by sodium and alcohol, giving a 60% yield of γ-*phenyl-n-butyl alcohol*, $CHMePh \cdot CH_2 \cdot CH_2 \cdot OH$, b. p. 134°/16 mm., D_4^{20} 0·9834, which resembles phenylpropyl and phenylethyl alcohols in odour. When heated with hydrochloric acid, the alcohol yields the corresponding *chloride*, b. p. 114—116°/17 mm., which is remarkably resistant to the usual chemical agents; it gives no reaction with potassium acetate and acetic acid, and when treated in light petroleum with aluminium chloride is hardly affected, yielding only traces of a non-volatile hydrocarbon and of a hydrocarbon, b. p.

90—100°/10 mm., possibly methylhydrindene; even with sodium the reaction does not occur normally, as the product is iso*butylbenzene*, b. p. 174—175°, D_4^{20} 0·8625. γ-*Phenyl*-n-*butyl bromide*, b. p. 108—110°/8 mm., can be obtained in a similar manner from the phenylbutyl alcohol, and reacts normally with ethyl sodiomalonate and ethyl sodioacetoacetate as well as with magnesium; the product from its slow reaction with sodium is a mixture of approximately equal quantities of *iso*butylbenzene and βη-*diphenyloctane*, a colourless liquid, b. p. 192—193°/10 mm., D_4^{20} 0·9539, resembling glycerol in appearance. γ-Phenylpropyl bromide, on the other hand, gives with sodium a 75% yield of aζ-diphenylhexane.

γ-*Phenyl*-β-*methylpropyl alcohol*, $CH_2Ph\cdot CHMe\cdot CH_2\cdot OH$, is a rather viscous oil, b. p. 128—129°/16 mm., D_4^{20} 0·9826, with an odour recalling linalool. It is obtained in 65% yield by the reduction of ethyl β-phenyl-a-methylpropionate by sodium and alcohol; the corresponding *phenylmethylpropyl chloride*, b. p. 112—114°/17 mm., is even less reactive than γ-phenyl-n-butyl chloride, for whilst the latter reacts with sodium iodide, the former fails to do so. The *bromide*, b. p. 110°/9 mm., however, behaves in a less abnormal manner, reacting with ethyl sodiomalonate and ethyl sodioacetoacetate; with sodium it reacts slowly, producing *iso*butylbenzene together with βe-*dibenzylhexane*, a viscous oil, b. p. 186—188°/8 mm., D_4^{20} 0·9457.

β-Phenyl-n-propyl alcohol, $CHMePh\cdot CH_2\cdot OH$, can be obtained by the reduction of the corresponding aldehyde (hydratropaldehyde: Claisen, A., 1905, i, 286). An attempt to prepare it through a-phenylethyl bromide by the Grignard reaction miscarried, because the action of magnesium was merely synthetic, producing βγ-diphenylbutane, m. p. 121—122°. The chloride of the above alcohol was prepared by a series of changes, commencing with β-phenyl-n-butyric acid; this reacts with phosphorus pentachloride, producing the acid *chloride*, b. p. 114°/11 mm., which with ammonia in ethereal solution yields the *amide*, m. p. 98·5°; this amide can be converted by the usual process with hypobromite into β-*phenyl*-n-*propylamine*, b. p. 104°/21 mm.; yellow *platinichloride*, m. p. 229° (decomp.); yellow *picrate*, m. p. 180°; *benzoyl* derivative, m. p. 85°. The last-named substance when fused with phosphorus pentachloride, and the mixture distilled under reduced pressure, gives a distillate which on hydrolysis with hydrochloric acid yields β-*phenyl*-n-*propyl chloride*, b. p. 98—100°/22 mm. The same chloride is obtained from benzo-o-β-chloro*iso*-propylanilide (the scission product of 3-methyldihydroindole: von Braun and Kirschbaum, A., 1912, i, 499) by cautious hydrolysis with hydrochloric acid and reduction of the diazo-compound of the resultant o-β-chloro*iso*propylaniline by alkaline stannous chloride solution. The yield of chloride in these two methods of preparation is not very satisfactory, and the product is very unreactive, being completely unaffected by the acetates of the alkali metals or of silver.

β-Phenyl-n-butaldehyde, $CHPhMe\cdot CH_2\cdot CHO$, was prepared by the "nitro" method, because in spite of its lack of reactivity, γ-phenyl-n-butyl chloride will undergo double decomposition with sodium iodide producing γ-*phenyl*-n-*butyl iodide*, a colourless liquid, b. p. 132°/14 mm.; this reacts in the usual manner with silver nitrite, and the reaction

mixture on distillation gives γ-*phenyl*-n-*butyl nitrite*, b. p. approx. 120°/12 mm., and α-*nitro*-γ-*phenyl*-n-*butane*, b. p. 138°/12 mm. The latter substance when treated in alcoholic solution with an equimolecular quantity of sodium hydroxide solution, and then with a solution of stannous chloride in hydrochloric acid, produces an oil which, after boiling with dilute sulphuric acid, yields β-*phenyl*-n-*butaldehyde*, b. p. 110°/9 mm.; *phenylhydrazone*, oily; the odour of the substance is sharp, and recalls that of phenylacetaldehyde.

D. F. T.

Cholesterol. XVI. Methyl *iso*Hexyl Ketone, a Degradation Product of Cholesterol. ADOLF WINDAUS and C. RESAU (*Ber.*, 1913, **46**, 1246—1248).—It has been observed by many workers that the oxidation of cholesterol by various methods is always accompanied by the formation of a substance of pleasant odour (compare Windaus, A., 1909, i, 920). The odoriferous substance has now been isolated by collecting the distillate from a boiling solution of cholesteryl acetate in acetic acid to which a solution of chromic acid was gradually added; acetic acid was removed from the distillate by sodium hydroxide solution, the liquid was again distilled, then dissolved in ether, and the acetone removed by shaking with water. Careful evaporation of the ether then gave a small residue of the pleasant smelling oil; *semicarbazone*, colourless, rectangular leaflets, m. p. 153—154°.

The composition, $C_9H_{19}ON_3$, of the semicarbazone suggested that the parent substance is an octanone, and a comparison of the m. p.'s of the semicarbazones indicated that the odoriferous substance was methyl *iso*hexyl ketone. For further confirmation, methyl *iso*hexyl ketone (Darzens, A., 1905, i, 172) was prepared (p-*nitrophenylhydrazone*, deep yellow crystals, m. p. 83°), and the identity of the semicarbazones was satisfactorily established.

D. F. T.

Preparation of Alkali Salts of *m*-Hydroxyphenoxypropane-sulphonic Acid. ALBERT WOLFF (D.R.-P. 258473).—*Sodium γ-chloro-β-hydroxypropane-α-sulphonate*, $CH_2Cl\cdot CH(OH)\cdot CH_2\cdot SO_3Na$, hard, colourless crystals, is obtained when a boiling aqueous solution of sodium sulphite (252 parts) in 500 parts of water is treated with 128 parts of α-dichlorohydrin.
Sodium β-hydroxy-γ-m-hydroxyphenoxypropane-α-sulphonate,
$$OH\cdot C_6H_4\cdot O\cdot CH_2\cdot CH(OH)\cdot CH_2\cdot SO_3Na,$$
a colourless, crystalline powder, can be prepared in 90% yield by heating a concentrated solution of catechol (110 parts) in 56 parts of sodium hydroxide with 196 parts of the foregoing sodium chlorohydroxypropanesulphonate during two hours under reflux in the presence of an indifferent gas such as hydrogen.

F. M. G. M.

Aromatic Telluretine Compounds. I. KARL LEDERER (*Ber.*, 1913, **46**, 1358—1362).—Diphenyl telluride has been condensed with bromoacetic acid and its esters, and compounds analogous to dimethylthetine bromide (Brown and Letts, A., 1874, 980) and to phenylmethylselenetine bromide (Pope and Neville, T., 1902, **81**, 1553) have been

obtained. The corresponding purely aromatic derivatives of sulphur and selenium could not be prepared.

Diphenyl telluride and methyl bromoacetate were left together for two or three days and then precipitated with ether. The *methyl* ester of *diphenyltelluretine bromide*, $TePh_2Br\cdot OH_2\cdot CO_2Me$, formed stout prisms from hot water, m. p. 105—106°. It was transformed by silver chloride into the *chloride*, m. p. 115—116°, with which zinc, gold, mercuric and platinic chlorides formed *double* salts. The *chromate* and *dichromate* could not be recrystallised, but the *picrate*,

$$C_6H_2(NO_2)_3\cdot O\cdot TePh_2\cdot CH_2\cdot CO_2Me.$$
formed well-defined, yellow needles, m. p. 144—145°. The *ethyl* ester, m. p. 63—64°, from ethyl bromoacetate was resolved by boiling water into its components. *Diphenyltelluretine bromide*, $TePh_2Br\cdot CH_2\cdot CO_2H$, itself was obtained from bromoacetic acid as a very hygroscopic mass, which, on shaking with silver oxide, gave *diphenyltelluretine*,

$$OH\cdot TePh_2\cdot CH_2\cdot CO_2H,$$
in the form of needles, m. p. 117—118°. The esters were hydrolysed by, and gave the same compound with, silver oxide.   J. C. W.

Preparation and Reactions of Acid Haloids. HERMANN STAUDINGER and E. ANTHES (*Ber.*, 1913, **46**, 1417—1426).—Acid chlorides can be converted into the corresponding bromides or iodides by the action of an excess of hydrogen bromide or hydrogen iodide, the reaction being interpreted according to the scheme :

$$R\cdot COCl + HI \rightleftharpoons R\cdot CClI\cdot OH \rightleftharpoons R\cdot COI + HCl.$$

The analogous reaction with hydrocyanic acid does not appear to be applicable to the production of nitriles.

Acetyl chloride was converted into almost pure acetyl bromide by the action of dry hydrogen bromide, the yield being 80%. Similarly, cooled acetyl chloride and hydrogen iodide gave a 70% yield of acetyl iodide, b. p. 105—108°. *Diphenylacetyl iodide*, pale yellow crystals, m. p. 46°, obtained from hydrogen iodide and diphenylacetyl chloride, was far more sensitive to the action of moisture than the latter substance, and, when heated at 150°, was decomposed with an almost quantitative elimination of carbon monoxide.

Benzoyl chloride was incompletely transformed into the bromide at the ordinary temperature; completely, however, at 100°. Benzoyl iodide was readily obtained in 95% yield from benzoyl chloride and hydrogen iodide. It had b. p. 109—109·5°/10 mm., and was colourless when pure, rapidly becoming yellow when preserved. The rate of decomposition of the benzoyl haloids by water has been investigated by shaking dilute ethereal solutions with water at 0° and titration of the acid formed. The iodide was found to be more readily decomposed than the bromide, and the latter more readily than the chloride. It was also noticed that elimination of the halogen acid was incomplete (compare Straus and Hüssy, A., 1909, i, 490). This was attributed to decomposition of the benzoyl haloid by ether, but no ethyl iodide and only traces of ethyl benzoate could be detected. When ether was replaced by toluene or xylene, sharp differences in the behaviour of the haloids could not be detected, probably owing to the slight solubility of water in the hydrocarbons. When heated in a sealed tube for twenty

hours at 190°, benzoyl iodide yielded iodine, benzoic acid, and black, asphalt-like products, but no carbon monoxide. At 250°, carbon monoxide was not liberated. At 500°, however, under 15—25 mm. pressure, benzoyl iodide yielded iodobenzene and iodine, whilst at 700° still more pronounced decomposition occurred. Benzoyl bromide was stable at 500°, but yielded bromobenzene at 700°, whilst decomposition of benzoyl chloride did not occur even at 700°.

Benzoyl iodide reacted vigorously with benzaldehyde with formation of *iodobenzyl benzoate*, $Ph \cdot CO_2 \cdot CHIPh$. The product so obtained was contaminated with iodine and could not be purified owing to its extreme instability. It was obtained, however, in colourless crystals, m. p. about 60°, by mixing the reagents in light petroleum solution. Benzoyl bromide reacted slowly with benzaldehyde, bromobenzyl benzoate, m. p. 65°, being formed, whilst no compound was obtained from benzoyl chloride.

Benzoyl iodide was scarcely affected by treatment with dry hydrogen chloride for three hours, but, after fifteen hours, the presence of benzoyl chloride was ascertained.

Benzoyl iodide reacted slowly with mercury at the ordinary temperature. At 120—130° reaction was complete within two to three days. Benzil did not appear to be formed. The main products, particularly at the higher temperature, were brown resins and a *substance*, m. p. 40°, which has not yet been investigated. In benzene solution, reaction occurred more slowly. In ethereal solution a ready action was observed, the products of which were ethyl iodide and ethyl benzoate.

Hydrogen bromide did not react with carbonyl chloride even at 200°. Slight reaction was observed when hydrogen iodide was mixed with gaseous carbonyl chloride.

Hydrogen cyanide appeared to be without action on boiling acetyl chloride or on oxalyl chloride at 15—20°. H. W.

The **Perkin Reaction.** HANS MEYER and ROBERT BEER (*Monatsh.*, 1913, **34**, 649—658).—In spite of the earlier investigations, it is still not certain whether in the Perkin synthesis the reaction occurs between the aldehyde and the salt of the fatty acid, or whether the anhydride plays a primary part.

It is now demonstrated that the yield of unsaturated acid depends largely on the aldehyde used; with sodium acetate and acetic anhydride, o-iodobenzaldehyde, o-chlorobenzaldehyde, o-nitrobenzaldehyde, benzaldehyde and p-dimethylaminobenzaldehyde gave yields in decreasing order of magnitude; with potassium acetate and acetic anhydride the relative behaviour of the various aldehydes appears to be the same, but the yields are uniformly better.

A comparison of the yields obtained by using o-chlorobenzaldehyde with the acetates of various metals in the presence of acetic anhydride shows that the alkali metals give better results the higher the atomic weight; lead acetate gives results comparable with the acetates of the alkali metals; mercuric acetate is poorer, whilst the acetates of copper and of the alkaline earth metals produce very small yields of chlorocinnamic acid.

The presence of an acid anhydride is not indispensable; benzaldehyde heated for twenty-six hours with potassium acetate and acetic acid gives a 30% yield of cinnamic acid. The yields of unsaturated acid when o-chlorobenzaldehyde is heated with an acetate and acetic acid is usually somewhat smaller than when acetic anhydride is used, but rubidium and lead acetates gave actually slightly better yields with the acid than with the anhydride. Michael's view (A., 1901, i, 358) that the Perkin reaction occurs between aldehyde and acid anhydride is, therefore, untenable.

The rôle of the acetic acid in the immediately preceding experiments appears to be merely that of solvent, and it is found that a 40% yield of unsaturated acid can be obtained by heating together o-chloro-benzaldehyde and potassium acetate, without the addition of a third substance, to 240° for thirty-six hours.   D. F. T.

The Halogen-Substituted Cinnamic Acids and their Behaviour in Ultra-violet Light. RICHARD STOERMER and PAUL HEYMANN (*Ber.*, 1913, **46**, 1249—1266. Compare A., 1912, i, 974).— In reply to Liebermann (this vol., i, 265), the authors submit that the former's proof of the structure of *allo*-cinnamic acid is not above suspicion, and that the nature of his experiments renders his decision merely a probability. The action of sulphuric acid on *allo*-cinnamic acid yields only ordinary cinnamic acid, and even if fuming sulphuric acid is used, the main product under suitable conditions is ordinary cinnamic acid accompanied by a relatively very small quantity of truxone (compare Liebermann, A., 1898, i, 662). It is also already recognised that there are exceptions to Liebermann's method of deciding the constitution of these isomerides by physical properties.

The main portion of the paper consists of the results of an extension of the investigation of the behaviour of ethylenic stereoisomerides in ultra-violet light (Stoermer, A., 1911, i, 295; 1910, i, 114).

α-Chlorocinnamic acid (Sudborough and James, T., 1906, **89**, 107), m. p. 137° (*aniline* salt, needles, m. p. 137°), exposed in acetic acid solution to the ultra-violet rays from a mercury lamp for twenty-one days is converted to the extent of 21% into *allo*-α-chlorocinnamic acid, m. p. 111° (*aniline* salt, needles, m. p. 96°). In a similar manner in methyl alcoholic solution, α-chlorocinnamamide, m. p. 121°, is converted to the extent of 10% into the amide (m. p. 134°) of the *allo*-acid in ten days.

α-Bromocinnamic acid, m. p. 131° (*aniline* salt, needles, m. p. 132°), when exposed in acetic acid to ultra-violet rays for twenty-one days is converted to the extent of 10% into *allo*-α-bromocinnamic acid, m. p. 120° (*aniline* salt, scales, m. p. 102°). When a methyl alcoholic solution of the *allo*-acid was exposed to ultra-violet rays, 71% was converted into the more stable isomeride. Similarly, α-bromocinnamamide, leaflets, m. p. 117°, in methyl-alcoholic solution is converted into the *allo*-isomeride (needles, m. p. 129°; 24% in 240 hours); the latter substance under similar treatment is re-converted to the extent of 50% into the original amide.

β-Bromocinnamic acid, needles or leaflets, m. p. 135°, is readily pro-

duced by submitting the *allo*-isomeride (Erlenmeyer, A., 1896, i, 46) in chloroform solution containing a little bromine to the action of sunlight; the product is an equilibrium mixture. The action of ultra-violet rays on an acetic acid solution for thirty-five days converted 40% of the acid into the *allo*-isomeride, m. p. 159—160°. Ultra-violet illumination converted 75% of the *allo*-acid in ethyl acetate solution into the ordinary acid.

Of the two β-chlorocinnamic acids, m. p. 142° and 132° respectively, the latter from its similarity to the analogous bromo-compound must be the *allo*-isomeride (compare Michael and Pendleton, A., 1889, 1063). The acetic acid solution of the former (*trans*-) compound is converted to the extent of 40% in twenty-one days into the *allo*-isomeride; the *aniline* salt, like that of *allo*-β-bromocinnamic acid, is unstable. In contact with bromine in sunlight the *allo*-acid is slowly re-converted into the other form.

The authors discontinue the use of the term *allo* in connexion with the αβ-dihalogen-substituted cinnamic acids, because the compounds which from their power of indone formation must be the *cis*-isomerides are more stable than the *trans*-isomerides.

cis αβ-Dichlorocinnamic acid, m. p. 121° (*aniline* salt, needles, m. p. 129°), when treated with cold sulphuric acid yields dichloroindone.

When a solution in acetic acid is submitted to ultra-violet rays for twenty-one days, 45% of the acid undergoes conversion into the hitherto unknown trans-*αβ-dichlorocinnamic acid*, rhombic tablets, m. p. 101°; *barium* salt, woolly needles; *aniline* salt, needles, m. p. 121°. The *trans*-acid is also obtained by the elimination of hydrogen chloride from the dichloride of α-chlorocinnamic acid by the action of potassium hydroxide solution; it is separated from the *cis*-isomeride simultaneously formed by the sparing solubility of the *potassium* salt of the *trans*-acid in alcohol. The action of sunlight on a chloroform solution of the *trans*-acid containing a little bromine causes a re-conversion into the *cis*-isomeride.

The action of bromine on phenylpropiolic acid solution in carbon disulphide in the absence of sunlight produces a mixture of *cis*-αβ-dibromocinnamic acid, yellow prisms, m. p. 100°, with the isomeric *trans*-acid, scales, m. p. 136°, in approximately the proportion 2 : 1; the two acids give *aniline* salts, needles, m. p. 126° and 128° respectively. In chloroform solution containing bromine, sunlight causes a partial change of the *trans*- into the *cis*-isomeride, but as the latter always predominates in the equilibrium mixture, it may be regarded as the more stable (compare Roser and Haselhoff, A., 1888, 1304). In ultra-violet light, the *cis*-acid, dissolved in acetic acid, is converted into the *trans*-acid to the extent of 40% in fourteen days. This *cis*-acid is converted by cold sulphuric acid into dibromoindone, but a much better method for the production of this substance is the action of aluminium chloride on the corresponding acid chloride in carbon disulphide solution at water-bath temperature; under these conditions a quantitative yield of dibromoindone, m. p. 123°, is obtained.

αβ-Di-iodocinnamic acid, m. p. 171° (Liebermann and Sachse, A., 1892, 470), decomposes when exposed in solution to ultra-violet rays; consequently no isomerisation could be detected; from the fact that the

known acid gives no indone formation with sulphuric acid, it is presumably of the *trans*-configuration.

Curves are given illustrating the course of the isomerisation of the acids, and the properties of the various acids are tabulated.

D. F. T.

The Constitution of Abietic Acid. PAUL LEVY (*Zeitsch. anorg. Chem.*, 1913, **81**, 145—155).—The evidence for the constitution of abietic acid is reviewed and a few new experiments described. Oxidation with nitric acid yields dinitropropane and *trans-cyclo*hexane-1 : 2-dicarboxylic acid. Abietic acid is related to retene and pinene, contains a *cyclo*hexane ring and an *iso*propyl group, and has its carboxyl group attached to a tertiary carbon atom. None of the formulæ hitherto proposed conforms to all these conditions, with the exception of that due to Easterfield and Bagley (T., 1904, **85**, 1241).

C. H. D.

Benzoylated Cyanohydrins and Amides from Aldehydes, and the Corresponding Hydroxy-acids JULES ALOY and CHARLES RABAUT (*Bull. Soc. chim.*, 1913, [iv], **13**, 457—460. Compare A., 1912, i, 462).—The preparation of benzoylated cyanohydrins by the action of benzoyl chloride on a mixture of an aldehyde with aqueous potassium cyanide has been extended to the fatty and heterocyclic series.

Benzoylglycollonitrile [*Benzoyloxyacetonitrile*], $OBz \cdot CH_2 \cdot CN$, from formaldehyde, forms well-defined, stable crystals, m. p. 26—27°, b. p. 275° or 165°/25 mm., which dissolve in concentrated hydrochloric acid or slightly warmed 60% sulphuric acid with the formation of *benzoyloxyacetamide*, $CO \cdot NH_2 \cdot CH_2 \cdot OBz$, in hard, lustrous crystals, m. p. 117—118°. Hydrolysis by hot dilute sodium hydroxide provides a convenient method for the preparation of glycollic acid, but when an insufficient quantity of very dilute alkali is employed and the reaction is arrested as soon as ammonia ceases to be liberated, benzoyloxyacetic acid, m. p. 79°, results. The *silver* salt was analysed. Alcoholic ammonia converts the nitrile into benzamide and the amide into benzamide and glycollamide. Sodium ethoxide causes no replacement by sodium in the $-CH_2$ group, but yields sodium cyanide and benzoate and ethyl benzoate, and in the case of benzoylmandelonitrile gives rise to benzoin.

Similarly, a-benzoyloxybutyronitrile is obtained from propaldehyde as an impure oil, which gives a *benzoyloxybutyramide*, $OBz \cdot CHEt \cdot CO \cdot NH_2$, m. p. 92°, and finally sodium a-hydroxybutyrate on hydrolysis, whilst *a-benzoyloxyisovaleronitrile*, $CHMe_2 \cdot CH(OBz) \cdot CN$, from *iso*butaldehyde, has m. p. 21—22°, and gives the *amide*, m. p. 98°, and then a-hydroxy-*iso*valeric acid on hydrolysis. *Benzoyloxyfurylacetonitrile*,

$$C_4H_3O \cdot CH(OBz) \cdot CN,$$
from furfuraldehyde, has m.p. 47—48°, but hydrolysis led to discoloured, indefinite substances.

The reaction is being extended to the ketones, in which case prolonged agitation is necessary (compare Francis and Davis, T., 1909, **95**, 1403 ; 1910, **97**, 949). J. C. W.

Racemisation of Tropic Acid and its Esters, together with a Theory of Racemisation, Substitution, and the Walden Inversion. JOHANNES GADAMER (*J. pr. Chem.*, 1913, [ii], 87, 312—392).—This paper contains a full and detailed account of the author's theory, a short description of which has already appeared (A., 1912, i, 934; compare Frankland, Presidential Address, T., 1913, 103, 722—725).

[With MAX KUNTZE.]—*Ethyl l-tropate*, prepared from ethyl iodide and silver *l*-tropate, has $[a]_D^{12}$ - 47 5° in alcoholic solution; the d-*ester* has $[a]_D^{14}$ + 46·6°.

Experiments are also described to show that the conversion of hyoscyamine into atropine is due to ionisation at the asymmetric atom.

F. B.

Preparation of an Inner Anhydride (Lactam) of 2-Aminobenzoyl-*o*-benzoic Acid. AKTIEN-GESELLSCHAFT FUR ANILIN-FABRIKATION (D.R.-P. 258343).—When the 2-aminobenzoyl-*o*-benzoic

(I.)

(II.)

acids of the general formula I (where X and Y may be hydrogen, methyl, a halogen or carboxylic group) are heated either alone with condensing agents or with solvents of high boiling point, they readily lose water and furnish inner anhydrides (lactams) of general formula II, and which are readily hydrolysed by alkali hydroxides to regenerate the parent substance.
When 2-*aminobenzoyl-o-benzoic acid*, rhombic crystals, m. p. 195° (with formation of the lactam), is heated at 200° with nitrobenzene it furnishes the corresponding lactam, m. p. 245°; the base accompanied by another isomeride is obtained by the nitration and subsequent reduction of benzoyl-*o*-benzoic acid and separation effected by means of the *calcium* salts.

2 : 5-*Diaminobenzoyl* o-benzoic acid, yellow needles, m. p. 265°, is obtained by heating 2-*amino-5-acetylaminobenzoyl-o-benzoic acid* (prepared by the nitration and subsequent reduction of 3-acetylaminobenzoyl-*o*-benzoic acid) with 30% sulphuric acid and subsequent decomposition of the *lactam* thus formed.

2-*Amino-5-acetylamino-4-carboxybenzoyl-o-benzoic acid*, yellow needles, m. p. 315°, is obtained by the oxidation (with potassium permanganate) of 2-*nitro-5-acetylamino-4-toluoyl-o-benzoic acid* and reduction of the so-obtained 2-*nitro-5-acetylamino-4-carboxybenzoyl-o-benzoic acid*, m. p. 247°; when heated with 30% sulphuric acid, the foregoing amino-acetylamino-base furnishes the *sulphate* of 2 : 5-*diamino-4-carboxybenzoyl-o-benzoic acid*, m. p. 340° (about), together with its *lactam*.

Reduction of the Anhydrides and Imides of Phthalic and Naphthalic Acids. ARNOLD REISSERT (*Ber.*, 1913, 46, 1484—1491). —The reduction of phthalic anhydride by zinc dust and acetic acid is known to give a complex mixture, from which diphthalyl, hydro-

diphthalyl-lactonic acid and phthalide can be isolated (Wislicenus, A., 1885, 57), whilst reduction by distillation with zinc dust yields a mixture of zinc phthalate and diphthalyl.

It is now discovered that when phthalic anhydride is gradually introduced into an agitated suspension of zinc dust in a solution of calcium chloride in 40% alcohol at 20—22° about half is converted into phthalic acid and half into diphthalyl-lactonic acid, for which the author prefers the formula $CO\diagdown\diagup_{C_6H_4}^{O}\diagup CH\cdot CO\cdot C_6H_4\cdot CO_2H$.

No satisfactory method for the preparation of phthalide from phthalic anhydride could be discovered, but it was found that phthalimide can be reduced by stirring with a suspension of zinc dust in cold $2N$-sodium hydroxide solution with the production of *hydroxyphthalimidine* (compare Graebe, A., 1885, 979), $C_6H_4\diagup_{CO}^{CH(OH)}\diagdown NH$, needles, m. p. 171—172°, which on boiling with acetic acid is converted into a *substance*, needles, m. p. 240—241°, of which the structure is probably $CO\diagdown_{NH}^{C_6H_4}\diagup CH—C(OH)\diagup_{CO}^{C_6H_4}\diagdown NH$. If after the reduction of phthalimide to hydroxyphthalimidine the reaction mixture containing excess of zinc is heated, a further reduction occurs and ammonia is liberated with the production of phthalide, $C_6H_4\diagup_{CH_2}^{CO}\diagdown O$, in almost theoretical yield.

If naphthalic anhydride is shaken with zinc dust and $2N$-sodium hydroxide solution, a blue solution is obtained, which on addition of more alkali and further shaking becomes red; on neutralisation a reddish-yellow, crystalline *substance*, $C_{24}H_{12}O_5$, m. p. 213—215°, is precipitated, whilst the naphthalic acid produced simultaneously remains in solution. The coloured reduction product, which the author designates *deoxynaphthalic anhydride*, possibly of the formula $CO\diagdown_{C_{10}H_6}^{O}\diagup C—C\diagup_{C_{10}H_6}^{O}\diagdown CO$, gives an unstable blue colour with

sodium carbonate solution and a stable red one with sodium hydroxide; on mixing intimately with concentrated ammonia solution the substance is converted into a *compound*, for which the annexed structure is suggested; this is a yellowish-red substance, which dissolves in alkali solutions with a bright blue or violet colour.

$)(OH)—C\diagdown_{C_{10}H_6}^{O}\diagup CO$
$\quad | \quad$
$\quad NH$

$CO\diagdown_{C_{10}H_6}^{O}\diagup C(OH)\diagup^{C}\diagdown_{C_{10}H_6}^{O}\diagup CO$

The reduction of naphthalimide by a similar process to that which was successful with phthalimide yielded only a pasty product.

Action of Acylamino-acid Chlorides on the Sodium Compounds of the Esters of Malonic and Cyanoacetic Acids. Siegmund Gabriel (*Ber.*, 1913, 46, 1319—1358).—A number of

phthaliminoacylmalonic esters of the series

$$C_8H_4O_2{:}N{\cdot}CXY{\cdot}CO{\cdot}CH(CO_2R)_2,$$
where X and Y = H or alkyl, have been prepared from acylamino-chlorides. It is found that the stability of the esters is enhanced when X and Y represent 1 or 2 alkyl groups, the non-substituted compounds having the character of strong acids and losing one $-CO_2R$ group on boiling with water (A., 1909, i, 491; 1911, i, 212). The presence of these groups is also 'a criterion for the pyrrolone condensation (A., 1911, i, 227), which also occurs when the malonic ester group is replaced by $-CH_2{\cdot}CN$, $-CH_2{\cdot}CO{\cdot}NH_2$, or by methyl, and when a benzoyl nucleus is substituted for the phthalyl group.

The same substituted phthaliminoacylmalonic esters are peculiar in their behaviour towards sodium alkyloxides, for the yellow sodium compound of the ester changes into the colourless neutral salt of a strong acid. Phenoxyacylmalonic esters underwent no such isomerism, whereas benzoylamino*iso*butyryl chloride condensed with methyl sodiomalonate to form a strongly acid compound with one methyl alcohol group less than the expected malonic ester. Benzoylmethyl-amino*iso*butyryl chloride, on the other hand, gave the malonic ester, from which it appears that an unsubstituted imino-group is necessary for the formation of the acidic compounds. These are shown to be derivatives of tetramic acid (Anschütz, A., 1912, i, 836), and their formation from methyl phthalimino*iso*butyrylmalonate, for example, presupposes the preliminary opening of the phthalyl ring and the addition of alcohol according to the scheme :

$$C_6H_4{<}^{CO}_{CO}{>}N{\cdot}CMe_2{\cdot}CO{\cdot}CH(CO_2Me)_2 + R{\cdot}OH$$

$$= CO_2R{\cdot}C_6H_4{\cdot}CO{\cdot}NH{\cdot}CMe_2{\cdot}CO{\cdot}CH(CO_2Me)_2$$

$$= CO_2R{\cdot}C_6H_4{\cdot}CO{\cdot}N{<}^{CO\text{----}CH{\cdot}CO_2Me}_{CMe_2{\cdot}CO} + CH_3{\cdot}OH.$$
This is supported by synthesis and by the fact that the methyl ethyl ester obtained from the methyl malonate and sodium ethoxide on the one hand, and from the ethyl malonate and sodium methoxide on the other, were isomeric. All these tetramic acid derivatives lose the ester group which is attached to the tetramic acid ring on hydrolysis with very dilute acids, and are decomposed by hydriodic acid into phthalic acid, alkyl iodide, carbon dioxide, and aminomethylbutanone.

[With JAMES COLMAN and KARL A. BÖTTCHER.]—For the preparation of ethyl phthalimino*iso*butyrylmalonate (A., 1911, i, 213), it is recommended to use enough ethyl sodiomalonate to form the *sodium* compound of the new ester. This forms light yellow needles, and gives a yellow, alkaline solution"which is decomposed by carbon dioxide. The ethyl alcoholic solution or the solution of the free ester mixed with sodium ethoxide gradually becomes pale in the cold, quickly on warming, and on evaporation deposits the white, isomeric *sodium* salt, $C_{19}H_{20}O_7NNa$, which gives a neutral solution and is only decomposed by mineral acids, when *ethyl carbethoxybenzoyldimethyltetramcarboxylate* [2 : 4-*diketo-1-benzoyl-5 : 5-dimethylpyrrolidine-o-3-dicarboxylate*],

$$CO_2Et{\cdot}C_6H_4{\cdot}CO{\cdot}N{<}^{CO\text{----}CH{\cdot}CO_2Et}_{CMe_2{\cdot}CO}\text{ , is formed as a crystalline}$$
powder, m. p. 81°. It has a strongly acid reaction, gives an orange-red colour with ferric chloride, and yields the *tetramic acid*,

$$CO_2Et \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot CO}{\overset{CO——CH_2}{\big<}},$$
on hydrolysis with warm dilute hydrochloric acid as a white powder, m. p. 198—199°, which disengages carbon dioxide from barium carbonate, gives a red coloration with ferric chloride, and an *ammonium* salt, in slender, white needles. The acid gives with one molecule of bromine the *monobromide*,

$$CO_2Et \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot CO}{\overset{CO——CHBr}{\big<}},$$
m. p. 159—160°, from glacial acetic acid, which forms a hydrate with $1H_2O$ in rhombic needles, m. p. 121—122°, from dilute acetic acid, and yields phthalic acid and *bromoaminomethylbutanone hydrobromide*, $CH_2Br \cdot CO \cdot CMe_2 \cdot NH_2,HBr$, in leaflets, m. p. 156°, on boiling with hydrobromic acid. This ketone reduces Fehling's solution and forms a *picrate*, which gives a turbid liquid at 135° becoming clear at 147°. Excess of bromine gives the *dibromide*, $C_{16}H_{15}O_5NBr_2$, m. p. 155°, which is neutral and can no longer become enolic. Chlorine yields the neutral *dichloride* in flat needles, m. p. 126—126·5°, from which the *hydrochloride* of *dichloroaminomethylbutanone*,

$$CHCl_2 \cdot CO \cdot CMe_2 \cdot NH_2,HCl,$$
m. p. 203°, was obtained. The *oxime*,

$$CO_2Et \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot C:N \cdot OH}{\overset{CO——CH_2}{\big<}},$$
forms microscopic crystals, m. p. 193°.

When the initial ethyl malonate is treated with sodium methoxide or when the sodium compound is left with methyl alcohol, the white, microcrystalline, neutral *sodium* salt, $C_{18}H_{18}O_7NNa$, is obtained, from which hydrochloric acid precipitates *ethyl carbomethoxybenzoyldimethyltetramcarboxylate* [*methyl ethyl* 2 : 4-*diketo*-1-*benzoyl*-5 : 5-*dimethylpyrrolidine*-o-3-*dicarboxylate*], $CO_2Me \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot CO}{\overset{CO——CH \cdot CO_2Et}{\big<}}$, which forms colourless needles, m. p. 133—134°, gives a *copper* and a *silver* salt, and, on hydrolysis, the *tetramic acid*, $C_{15}H_{15}O_5N$, in needles, m. p. 210—211°. The acid distils unchanged in a vacuum, yields an *ammonium* salt, an *oxime*, $C_{15}H_{16}O_5N_2$, in sparkling prisms, m. p. 210°, and a *hydrazone*, $C_{15}H_{17}O_4N_3$, in short prisms, m. p. 222—223°. The *methyl ether*, $CO_2Me \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot C \cdot OMe}{\overset{CO——CH}{\big<}}$, is obtained by the action of methyl alcohol and hydrogen chloride as a crystalline powder, m. p. 103—104°, which gives no colour with ferric chloride, is insoluble in alkalis, and yields a *bromo*-derivative, $C_{16}H_{16}O_5NBr$, in matted needles, m. p. 140°. The *acetyl* compound,

$$CO_2Me \cdot C_6H_4 \cdot CO \cdot N \underset{CMe_2 \cdot C \cdot OAc}{\overset{CO——CH}{\big<}},$$
forms crystalline granules, m. p. 119—120°. The *monobromo*-derivative forms flat, rectangular prisms, m. p. 221°, which yield an *ammonium* salt and the above bromoaminomethylbutanone hydro-

bromide. The *dibromo*-derivative forms glistening needles, m. p. 193°, and the *dichloride*, m. p. 172—173°, yields the above dichloroaminomethylbutanone salt on hydrolysis.

Methyl phthaliminoi-obutyrylmalonate,

$$C_8H_4O_2:N\cdot CMe_2\cdot CO\cdot CH(CO_2Me)_2,$$
forms colourless, rhombohedral crystals, m. p. 91°, which give a dark cherry-red colour with ferric chloride. The *sodium* compound is yellow, reacts alkaline, and changes in methyl alcohol into the colourless, neutral *isomeride*, from which hydrochloric acid liberates *methyl carbomethoxybenzoyldimethyltetramcarboxylate* [2 : 4-*diketo*-1-*benzoyl*-5 : 5-*dimethylpyrrolidine*-o-3-*dicarboxylate*],

$$CO_2Me\cdot C_6H_4\cdot CO\cdot N{<}^{CO——CH\cdot CO_2Me}_{CMe_2\cdot CH},$$
in short, thick columns, m. p. 155°, which may be distilled in a vacuum. It forms a *silver* salt, and gives the above tetramic acid, m. p. 210—211°, on hydrolysis. In order to synthesise the compound, α-amino*iso*butyric acid was condensed with the chloride of methyl hydrogen phthalate (Meyer, A., 1901, i, 750) to form *carbomethoxybenzoylamino*iso*butyric acid*, $CO_2Me\cdot C_6H_4\cdot CO\cdot NH\cdot CMe_2\cdot CO_2H$, in rhombic tablets, m. p. 168°. This was converted into the *chloride* by means of thionyl chloride, and then condensed with methyl sodiomalonate and the product identified with the expected ester, m. p. 155°. When the methyl ester, m. p. 91°, is allowed to react with sodium ethoxide, the neutral *sodium* salt of *methyl carbethoxybenzoyldimethyltetramcarboxylate*,

$$CO_2Et\cdot C_6H_4\cdot CO\cdot N{<}^{CO——CH\cdot CO_2Me}_{CMe_2\cdot CO},$$
